Among the members of the great, yet not fully specialized, family of the Colubridae, many North American snakes are placed. The green-snake or grass-snake, *Cyclophis vernula*, of the United States is very common, especially in New England. It is very often found in the tall grass, or even among the branches of shrubs. It is generally very gentle in its habits, but will occasionally show fight, inflicting trifling wounds with its teeth. The members of this genus, like the more strictly arboreal bush-colubers, are more frequent in America than in the old world. The mountain black-snake, *Coluber obsoletus*, having keeled scales, is a large snake found chiefly along the Alleghanies. *C. guttatus*, the brightly colored corn-snake of the South, is most active after dark. *C. quatrivittatus*, called chicken-snake, often enters human dwellings of the humbler sort, and does good by killing rats and mice; like others of its genus it often destroys young chickens. *C. vulpinus*, the fox-snake, has a rather wide range. The common black-snake, *Batrachion constrictor*, has one of the widest geographical ranges of any known species. The swift, bold, and active creature will fight bravely if brought to a pass whence there is no easy escape, and many stories are told of its fierceness and intrepidity, some of which, like too many snake-stories, are no doubt exaggerations. Though not venomous the black-snake fights and destroys the more slug-

gish rattlesnake. *B. flagelliformis*, the long, swift, and harmless, though much dreaded, coach-whip snake, is very common in the South-eastern States. *B. tentatum* has a wide Western range. A green species of *Batrachion* is mentioned as occasionally sharing the hospitalities of the prairie-dog's burrow, together with the rattlesnake and the burrowing-owl.

The Fresh-water colubrine snakes are exceedingly well represented in North America. *Tropidonotus sipedon* is one of our commonest water-snakes, if, indeed, it be not the commonest of North American serpents. There are a dozen other American species of this genus. They feed largely on fish, frogs, and tadpoles. Country-people usually consider them venomous, probably on account of their belligerent spirit when captured. The garter-snake genus (*Eutania*) is represented here by some 20 recognized species. *E. saurita* and *E. sordalis* are our commonest garter-snakes. The latter has little fondness for the water. It is often found near piles of decaying chips and saw-dust, where it feeds upon larvae and wood-ticks. It is harmless, but will sometimes fight bravely. *Storeria occipitomaculata* and *S. dekayi* are small species and not uncommon northward. The so-called Hoop-snake, *Ahaetor erythrogrammus*, is a common species in the Southern and Western States. The prevalent belief that it can take its tail in its mouth and roll along the ground like a hoop is entirely incorrect. The horn-snake of the South is *Furancia abacura*, a species much resembling the hoop-snake. The water-snakes of the family Homalopsidae are represented in the U. S. by the genus *Helicops*, one species of which has been found in Florida.

Of the "night tree-snakes" (Dipsadidae), one species of *Dipsas* is found in Texas and Arizona, representing a remarkable and widely disseminated genus. The species are generally long and slender. The name *Dipsas* is Greek, and signifies "thirsty"; the ancients believed that the snake of this name had an unquenchable thirst which it imparted to those who were bitten by it. It is needless to add that this belief was not founded upon facts. The great black gopher-snake, or indigo-snake of the Southern cotton-belt (*Spilotes cooperi*), is said to attain the length of 12 feet. It is bold and active and is believed occasionally to occupy the same burrow with one or more of the larger tortoises (also locally called "gophers" or burrowers). This genus is chiefly South American. The common pine-snake or bull-snake of the east (*Ptyophis melanoturus*) is a large and very swift creature, common in pine-forests. *P. bellona* is a very common and important Western form, which is not only harmless but exceedingly useful as a vermin-destroyer. The swift and spiteful snakes of the genus *Dromicus* are common in tropical America, and *D. flavilatus* is sparingly found in the cotton-growing States. It is grouped with the semi-arboreal colubrines. The true tree-snakes, or Dendrophidae, are very abundant in tropical America, and a few species are Mexican. The Dryophidae, or whip-snakes, are very slender tropical forms, some of them American. A few of the Scytalidae are Mexican, and others are South American.

The family of Amblycephalidae, or blunt-heads (chiefly East Indian), has several South American representatives.

To the Erycidae, or sand-snakes, mostly old-world desert forms with some boa-like features, belong several American genera; and *Charina*, *Wenona*, and *Lichanura* are strictly North American forms, presenting many points of interest to the naturalist.

The very remarkable old-world family Pythonidae has but a single known American representative—a little known and very singular species of *Loxocemus*. On the contrary, the Boidae (excepting a few Poly-

nesian and Australian species) are all American. *Boa imperator*, the emperor-snake of Mexico, approaches closely to the well-known *B. constrictor* of S. America. Closely allied are *B. mexicana* and *B. isthmica*. Here belongs the anaconda (*q. v.*) of literature, though the original anaconda was East Indian or Ceylonese. *Xiphosoma caninum* is the dog-headed boa of Brazil, with a generally greenish hue, varied with bands and spots of lighter tint.

Epicrates cencleria is one of the species called aboma (which is strictly the name of an African snake). The ancient Mexicans used to worship this serpent with bloody rites.

The venomous snakes of America are very numerous. The great family Elapidae has many genera—one of which, *Elaps* proper, has many South American species. *E. fulvus* is the showily variegated little harlequin snake of the Southern States. It is singular that this little reptile, though undoubtedly venomous, is regarded by almost all who know it as perfectly harmless. At ordinary times it is not easy to provoke it to bite.

Of the exceedingly venomous Hydrophidae, or sea-snakes, so common in the Indian Ocean, only one species, *Pelamis bicolor*, ranges eastward across the Pacific to tropical America; and the same or some other has been reported, perhaps incorrectly, from the Atlantic waters of Central America. The exceedingly venomous family, Causidae, chiefly African, has one Venezuelan representative, a *Dinodipsas*. A characteristic family, though one not peculiar to America, is that of the Crotalidae or pit-vipers. The common copper-head, *Ancistrodon contortrix*, has a wide range in N. America, and is exceedingly venomous. Still more dreaded is the water-moccasin, *A. piscivorus*, of the Southern States. The terrible fer-de-lance, *Trigonoccephalus lanceolatus*, is found in some of the West Indian Islands.

For a description of the Rattlesnake the reader is referred to the *ENCYCLOPEDIA BRITANNICA*. Besides the species named we may mention as noteworthy

THE RATTLE-SNAKE.

Crotalus molossus of New Mexico and Arizona; *C. confluent*, the common prairie-rattlesnake; *C. lucifer*, the black rattlesnake of the Pacific States; *C. cerastes*, the horned rattler, or side-winder, of New Mexico. The small rattlesnakes of the genus *Caulidona* are very commonly designated by the aboriginal name of Massasauga. There has been described a species of rattlesnake called *Aplouspis lepida*, from Western Texas, which has been considered the most highly specialized of all the group, if not of all existing snakes.

It is probable that every state and territory of the Union is at least locally infested by rattlesnakes of one or more species. In the New England States they are for the most part limited to very rocky and thinly settled tracts—the finely splintered trappean surfaces on the sunny sides of such ridges as that of Mt. Holyoke and Mt. Tom being especially adapted to their habits. The abandonment and reforestation of old farm-lands in New England seems to be lead-

ing to the return of the rattlesnake to districts where he has long been a stranger. It is asserted that the rattlesnake of New England is especially dangerous, and that the proportion of deaths following from its bite is much larger than that observed in more southerly latitudes. Much more certain is it that the largest species of rattlesnakes are as a rule the most deadly; the bite of the little "massasauga" being not nearly so dangerous as that of *Crotalus horridus*, or the South American *C. durissus*, or the great diamond rattlesnake that haunts the swamps and hammock-lands of the Gulf States.

The one remedy, and the only one worth considering for rattlesnake-bite, is whiskey or its equivalent. The snake-poison is a tremendous heart-depressant, and the only remedy is the direct counter-poison (or "physiological antidote") of alcohol, a heart stimulant; for there is no known and available chemical antidote. The amount of stimulation the patient will generally bear after a snake-bite is very wonderful. The remedy should be pushed vigorously, but not inconsiderately. As a rule, when signs of intoxication begin to be discernible the stimulus must be given with greater moderation. If spirits of ammonia, or pure ethylic ether, be at hand, it is well to begin the treatment with a large dose of one or both, by reason of their speedy action; but the slower alcoholic stimulation is much more effective.

It is well known that savages everywhere, at least when pushed by hunger, will eat the flesh of serpents. It is equally well known that in Europe asp's flesh was regarded (as it still is locally) as a sovereign remedy for various ills and diseases; and one theory of the derivation of the name *aspic* as given to a favorite made-dish of the European cuisine is that it originally contained stewed asps. It is, however, much less generally known to the reading public that the rattlesnake is eaten by white people, not only in Lower Canada but also as far south as the Gulf of Mexico. At a time not yet distant the flesh of the rattlesnake was served up upon the well-appointed tables of wealthy and not unrefined planters and prosperous towns-people in the Gulf States. By way of euphemism the serpent's flesh was called "musical squirrel," or by some other similar disguise. All the recorded testimony confirms the statement that rattlesnake meat is tender and delicate and of good flavor. Rattlesnake's oil is regularly kept for sale in many drug-stores. Thousands of country-folk believe that it has singular virtues as a remedy; and along with skunk's-grease, opossum-fat, dog-fat, and raccoon-tallow, it meets with a ready sale at good prices. Its virtues are, in fact, much the same as those of lard or goose-grease. There is no reason to believe that it has any special qualities which give it a value above that of any other animal-oil.

The name "blind-worm," applied in the early part of this article to snakes of the genus *Typhlops* and the allied forms, is in English literature given to *Anguis fragilis*, "which is neither blind nor a worm," but a snake-like lizard, mentioned here solely as one of a rather numerous group of limbless lizards, popularly confounded with true snakes. One of the most interesting of these creatures is the "glass-snake," *Ophiosaurus ventralis* of the Southern States, so called from the brittleness of its tail, which is very readily broken off. Very similar are the European glass-snake, *Pseudopus pallasi*, *P. gracilis* of India, and the African *Hyalosaurus*. Australia has a great number of limbless and snake-like lizards, and there are several in the Californian region. Among other limbless vertebrates are the *Cæciliidae*, chiefly tropical and subterranean in their habits, often eyeless or nearly so. They are batrachians, and not true reptiles. The *Amphisbæniidae*, also serpent-like and nearly blind, are true lizards. They

are mostly South American, but *Rhinocera floridana*, the "thunder-worm" of Florida, may be assigned to the same family. (c. w. g.)

SOAP. The manufacture of soap has for many years been an American industry of considerable importance, its growth being such that the United States has long ceased to be a considerable market for European soaps, and now competes with England and France in exportation to foreign countries. Marseilles, long the market of the finer toilet-soaps, no longer enjoys a monopoly in this direction, large quantities of such soaps being now made in this country, both for home consumption and for export. Soap and candles (formerly made at the same factories) were imported largely into the United States until about 1824, when, under the encouragement of a protective tariff, their manufacture became active in this country. Up to that time only soft soap (largely as a domestic manufacture) and common laundry and toilet soaps had been made here, but better qualities were now manufactured, and on a scale that greatly reduced importations. In 1864 the duties were increased from 3 to 10 cents per lb., since which time the finest grades of perfumed toilet-soaps have been manufactured in America in quantities sufficient not only to supply the home market but to sell extensively abroad.

The primitive American soaps were made with potash instead of soda, potash being then derived from the forest-refuse in much greater quantities than at present. This is still the case with home-made soaps where potash continues a common product, as in Canada and several of the States, but the cheap production of caustic soda during the present century, by what is known as the Le Blanc process, has in most places replaced potash by soda as the alkali of soap. The kitchen fats, chiefly those of beef and mutton, were saponified with crude potash to form the soft soap of the early American household. The recipe ordinarily used, and which has become traditional in country-kitchens, is the following: 12 lbs. of fat and 9 lbs. of potash are steeped in boiling water in a cask, the water being added 3 gallons at a time every 24 hours until 12 gallons have been added. Saponification soon begins, but takes many days for its completion, the mixture being frequently stirred. When completed all the fat lumps have disappeared, the soap has a silky lustre when stirred, and is of the consistency of a jelly. It is a powerful detergent for coarser household purposes, and is preferred to hard soap for scrubbing floors, washing crockery, and the like. It is not a true soap, chemically considered, but a solution of a potash soap in caustic lye, with free glycerine. In improved processes the potash lye is boiled with kitchen fats and other oily substances until the mixture becomes a clear, transparent, slimy liquid. The detergent powers of this are very great, from its strongly alkaline condition, and it is much esteemed for such processes as scouring wool, coarse linens, etc. The hard bar-soaps of America are made in a very similar manner, but of choicer materials, to which are added 25 to 30 per cent. of powdered rosin. At the present day the manufacture of soap is an American industry of considerable importance, several of the factories confining themselves to the choicest grades of fancy and toilet soaps, in the production of which they are on a level with the best European manufacturers. In 1880 there were 629 establishments engaged in this business in the United States, employing 5,589 hands, and yielding a product valued at \$26,552,627. Nearly one-fourth of the whole product was made in the State of New York; Massachusetts, Pennsylvania, Illinois, and New Jersey coming next in order. We have no later statistics of manufacture, but the importations and

exportations for 1886 were as follows: Toilet soaps imported—value, \$178,673; other grades, \$258,623; total value, \$437,296. Exportations of toilet and fancy soaps, \$60,646; of other grades, \$772,131; total value, \$832,777—the exportations of soap thus exceeding the importations about \$400,000. This, then, is one of the industries in which the United States not only can stand alone, but is able to compete successfully with Europe for a foreign market. (c. m.)

SOAP STONE. See TALC.

SOCIALISM. No movement of modern times has awakened or deserved greater attention than the one indicated by this title. See Vol. XXII. p. 205 (p. 216 Am. Rep.). Its accurate definition is exceedingly difficult, owing to an entire lack of agreement concerning the true limits of the word "Socialism." In general, it may be described as that movement which seeks by economic changes to destroy the existing inequalities of the world's social conditions. For convenience of discussion it may be best to divide the Socialists of America into two classes: First, those who believe the necessary changes can be secured only by the early or immediate employment of force; and, second, those who believe in more conservative methods, such as agitation and peaceful combination. Into all socialistic schemes the idea of governmental change enters, with this radical difference, however: some Socialists rely upon the final abolition of existing forms of government and seek the establishment of a pure democracy, while others insist upon giving to government a paternal form, thus increasing its function and power instead of diminishing it. Of course, its paternal functions are to be exercised in the interest of the wage-toilers of the country.

1. The more radical wing of the Socialists of America has given expression to its life and views in the several platforms and declarations of the International Working People's Associations and the International Workmen's Association, sometimes designated as the "Blacks" and "Reds," respectively. The latter are regarded as the more moderate and conservative wing, and have probably the larger constituency in America. The International Working People's Association ("Blacks"), in a manifesto issued a few years ago in New York, after reciting the grievances under which the laboring classes rest by reason of the oppressions of capital, proceeds to declare "that they (the oppressors) will not resign these privileges voluntarily we know, that they will not make any concession we likewise know. Since we must then rely upon the kindness of our masters for whatever redress we have, and knowing that from them no good may be expected, there remains but one recourse—FORCE. Our forefathers have not only told us that against despots force is justifiable, because it is the only means, but they themselves have set the immemorial example." They avow, among others, the following demands: 1. Destruction of the existing class-rule by all means, i.e., energetic, relentless, and international action. 2. Establishment of a free society, based upon co-operative organization of production. 3. Free exchange of productions of all sorts. 4. Secular education. 5. Equal rights for all sexes and races. 6. Public affairs to be regulated by free contract. This section of Socialists believes in the use of dynamite and other explosives as means to the end of social regeneration. The International Workmen's Association published in 1884 a *Declaration of the Rights of Man*, which is given to the world in a brief treatise on *Socialism*, by A. J. Starkweather and S. Robert Wilson. This manifesto was issued in San Francisco, Cal. It declares that liberty is the power which belongs to a man of exercising all his faculties at pleasure.

Every individual is entitled to an equal proportional share of all the natural advantages of earth. The whole people should hold the land, light, air, and water, together with other of nature's resources, as the natural heritage in common of all mankind. Every individual is entitled to an equal proportionate share of all accumulated wealth created by past generations, and that wealth should be held by society as the natural heritage in common of all mankind. Debt, profit, interest, rent, and the competitive system of industry are declared instruments of degradation and tyranny, and cancers upon the social body. So, also, are the present methods of punishing crime, the present monetary system, the present methods of suffrage, education, jurisprudence, church and military. The right of property is substantially limited by the rights acquired by production. So long as members of society fulfil their portion of the social contract they have a right to demand of society the means necessary to provide for their subsistence. Society is bound also to insure the means of existence to those who are incapable of labor. Every act against the imprescriptible rights of man, by whomsoever exercised, even in the name of the law itself, and within the forms it prescribes, is arbitrary and void. The very respect due to law forbids submission to it, and if the attempt be made to execute such act by violence or by artifice, it is not only permitted, but enjoined upon every individual to repel such assaults even by force. Government should be as nearly as possible pure democracy. Governments, as at present constituted, are simply means of enslavement. Appended to this Declaration is an explanation of the method of organization of the I. W. A., in which the individual workman is invited to gather a group of seven others, and, after a series of educational conferences, the members of this group are to become individually the leaders of other groups of eight, and so on—the object of these gatherings is stated to be education—in rights and in chemistry!

2. Next should be named that class of Socialists seeking immediate social renovation by sweeping and revolutionary changes, but by methods which are conservative. The Socialist Labor Party most distinctly represents this class; it proposes to accomplish its ends gradually, but seeks as present possibilities: 1. The establishment of a Bureau of Labor in connection with the U. S. government. 2. Reduction in the hours of labor. 3. Abolition of convict labor. 4. The enactment of an employers' liability law. 5. The prohibition of child labor. 6. Compulsory education. 7. Factory, mine, and workshop inspection. 8. Inspection of food and dwellings. 9. Payment of all wages in cash.

3. A still more modified form of socialism has arisen in connection with the adoption of the theories of Henry George as expressed in his work *Progress and Poverty*. This has given rise to the formation of the Anti-Poverty Society, whose work for the present is mainly educational, but which aims at a final enforcement of its views by political action. It declares: "That all men are created by Almighty God with certain inalienable rights; that these inalienable rights are rights to life, liberty, and the pursuit of happiness; that life cannot be had without proper access to the materials of which this earth is made, and that therefore God has given an equal and indefeasible right to each and everyone of his children of access to these materials; that no prescription, no vested right, no law can deprive the child of a beggar of the same right as the child that is born of an imperial throne possesses to equal common ownership of the bounties of nature." Proceeding upon this assumption, it is claimed that the painful inequalities of existence are due to the infraction of a natural law. Land being the common property

of all, the wealthy landholder is enriched by an increase of value in his land which is an "unearned increment;" and the population which caused the increase ought to be rewarded with what itself has created. All private ownership in land should be abolished, and the community should take in taxation its rental value.

4. Christian socialism. Recognizing the manifest wrongs and burdens concomitant to our present economic conditions, a large number of Christian writers have addressed themselves to this subject. Their labors have been confined to seeking ameliorations rather than radical changes at the present, and to emphasizing the idea of human brotherhood, in response to which, it is claimed, men should seek more nearly to equalize the conditions of human life by justice that is kind rather than to repair the ravages of injustice by charity. This form of socialism, which is claimed to grow out of the life of Jesus and from the very spirit of the gospels, is a powerful factor in the life of America to-day, and cannot fail of a favorable reaction on the violent spirit of discontent excited by philosophic socialism.

American Socialists, with the possible exception of many in the last-named class, are generally agreed, according to Prof. R. T. Ely, on four points: the first of these is that it is desirable to abolish private property in instruments of production, not in income, so far as this consists simply in articles of use and enjoyment and which cannot serve as a further basis of production. 2. Not to abolish capital, but the distinct class of capitalists. 3. They believe in the use of the best machinery and in improved methods of production, and in the organization of production on a vast international basis. 4. They believe in co-operation as a substitute for the wage-system.

The growth of socialism in this country has been rapid and will probably keep pace with the just causes of discontent. The centralization of wealth, the rise of monopolies, the control of many of the necessities of life by gigantic "trusts," accompanied as they often are by combinations on the part of employers to restrict the wages and restrain the liberty of the employed by means of "ironclad oaths" and "black lists"—these are denounced as artificial forms of oppression which are superadded to the natural disadvantages arising for the laboring classes by reason of the use of improved means of production and the rapid increase of laborers by unrestricted immigration. The *Republic* of Plato and the *Utopia* of Sir Thomas More were early expressions of human yearning to which Christian prophecy responds in the promise of a millennium. It is not improbable that a gradual advance in liberal legislation, whereby the powers of avarice shall be limited and the rights of the toiling masses shall be restored, may avert the use of violence, and that in the orderly advance of a Christian civilization there shall come at last to the people of this country an equitable and universal distribution of those advantages which our possession of nature's gifts and our inheritance of centuries of advance in intelligence and power shall afford.

The socialism that is linked to materialism is threatening and violent; its only hope of ameliorating the condition of the oppressed is in the use of force. Those forms of socialism which are affected by Christian thought are hopeful of a solution of existing difficulties by methods that are educational and peaceful. That the wrongs complained of are real, that they are becoming more burdensome with the advance of time, and that they will become unendurable if left to go on unchecked, is apparent to every thoughtful mind. The cure by violence is full of suggestions of horror. It may be avoided if, instead of ignoring these wrongs, men will address

themselves to the remedy, and, by giving emphasis to the idea of human brotherhood, secure such concessions to the world's toilers as shall bring greater possibilities of happiness to all.

Literature: W. H. Fremantle, *The World as the Subject of Redemption* (London, 1885); Henry George, *Progress and Poverty* (New York, 1883); R. T. Ely, *The Labor Question* (New York, 1886); A. J. Starkweather and S. Robert Wilson, *Socialism* (New York, 1884). A brief list is also appended of periodicals devoted to the dissemination of socialistic ideas. *Truth*, monthly, San Francisco; Burnette G. Haskell, editor; *The Labor Enquirer*, weekly, Denver; J. R. Buchanan, editor; *Examiner*, weekly, Hartford; *Sociologist*, monthly, Knoxville, Tenn.; *New-Yorker Volks Zeitung*, daily, New York; *Arbeiter Zeitung*, daily, Chicago; *Tageblatt*, daily, Philadelphia; *Freiheit*, weekly, New York; *Vorbote*, weekly, Chicago; *Die Fackel*, weekly, Chicago; *The Free Soiler*, monthly, New York; *Journal of United Labor*, Philadelphia; *The Protest*, Exeter, N. H.; *Man*, weekly, New York; *The Truth Seeker*, weekly, New York; *The Radical Review*, Chicago; *Luzifer*, weekly, Valley Falls, Kan.; *The Non-Conformist*, daily, Haverhill, Mass.; *Mail*, daily, Stockton, Cal.; *Labor Herald*, Pittsburg; *Labor Standard*, Paterson, N. J.; *Labor Free Press*, Baltimore; *Advertier*, Trenton, N. J.; *Irish World*, New York; *Union*, St. Louis; *Vidette*, Salem, Oregon. All the last named are weekly papers. (T. A. K. G.)

SOCIETIES, MUTUAL AID. Man is a gregarious animal in a far more comprehensive sense than any of the lower animals. Each community not only combines as a whole for mutual aid and assistance, but within every civilized community are numerous minor aggregations, wheels within wheels, combined for more specialized purposes of mutual benefit, and designed to cover almost all the needs and wishes of man which can be helped by association. There are numerous societies for political, literary, scientific, social, and recreative purposes, whose object is to aid each other in amusement, the acquisition of knowledge, the gaining of public rights, etc., but none of these are included within our present purpose, which is confined to the consideration of societies organized to aid their members in gaining the means of livelihood, and in most of which pecuniary help in case of sickness or death is a leading feature.

Societies of this character have existed from a remote period. In ancient times they can be traced in Greece and were numerous in the Roman Empire, their methods and aims being not unlike those of modern societies. In the mediæval period the principle of mutual benefit association was active. The trade guilds, the most important of the associations of that era, were numerous and powerful, and in certain localities went so far beyond their original function as to exercise a controlling influence upon government. These associations differed radically from the trade unions of to-day. They were organized not against capital but against labor competition. Labor in those days was its own employer, the masters had begun life as mechanics, and the interest of one was the interest of all. The guilds established rigid rules to prevent an overflow of labor from without into their organizations, and with such effect as to divide the lower rank of society into two classes: one of masters, mechanics, and apprentices in the trade guilds; one of laborers, tamps, and beggars who were refused admittance to these guilds. It was an artificial state of society, but it long held its own in opposition to the force of the natural law of industry. The guilds were important institutions in that era, and accumulated property, much of which still exists, though the societies themselves have been reduced to mere shadows, and exist simply to take care of this property. Pecuniary aid in case of distress was a feature of the guilds, and was a leading characteristic of certain charitable and social societies which existed at the same time, and which approached our modern beneficial societies in character and purposes, the

supply of a burial fund being one of their leading features.

There is, however, a definite line of division between mediæval and modern times in respect to the principles of labor association. The rise of the factory system, and the employment of great sums of money in single manufacturing enterprises, gave the death-blow to the guilds. They vanished as vital organizations, and have been succeeded by the trade unions, in which the principle of exclusion of outside labor still exists, but only as a minor object, the major object being that of preventing the encroachments of capital. The contest is now for an equitable division between labor and capital of the profits arising from manufacturing enterprise, this being one of the most difficult questions to settle that has arisen in modern history.

By the side of these trade unions have arisen many mutual aid, or "friendly societies" as they are called in England, which have no connection with the labor question, but limit their purposes to the single one of pecuniary assistance in the case of accident, sickness, or death. In these societies the members make weekly or monthly contributions to a common fund, accumulating a sum which is paid out again in definite weekly amounts in case of sickness or accident to any member, and to aid in the burial of members in case of death. In other cases there is no payment except a given sum for burial, while some mechanics' societies have a fund to pay for loss of tools by accident or otherwise.

As the trade unions are all new societies, none of them being continuations of the guilds, so the same may be said of the mutual aid societies, with one exception, that of the Free Masons, which alone has come down to us from mediæval times. (See articles on FREE MASONRY in the *ENCYCLOPEDIA BRITANNICA* and in this work.) The Free Masons is the strongest and most influential of modern secret societies and possesses a very intricate organization, the main body being supplemented by higher "degrees," some of which are almost distinct societies in themselves.

Next in importance comes the Independent Order of Odd Fellows, a society of English origin but which, like the Masons, has become very strong within the United States. The exact date of its origin is not known, the first trace of its existence being in 1745, when it seems to have constituted a secret society for convivial purposes, with a small fund for the relief of poor and burial of deceased members. About the same time another important English society, the Ancient Order of Foresters, came into existence. This is to-day of considerable strength in England, and has established itself to some extent in the United States. The Order of Druids is another English society of some strength, while several others might be named of minor importance. In the last century these societies had not the definite organization and purposes of more recent times, their beneficial feature being of secondary importance. It was in 1812 that the Odd Fellows Society reorganized itself for the purpose of mutual assistance in prescribed sums in case of sickness and in the defraying of funeral expenses. In imitation of the Free Masons, it devised pass-words and signs for the mutual recognition of members and to prevent imposture, established new rules of order and better defined conditions of management, and assumed its present name of "The Independent Order of Odd Fellows." This new departure was a distinct advance on the informal workings of the preceding benevolent and charitable institutions, and gave the cue to the organization of the more recent societies. The Free Masons alone retain the generalized conditions of pecuniary aid of the earlier period, other societies binding themselves to the payment of fixed

sums in case of sickness or death. The first governmental recognition of these associations was made in England in 1793, when an act was passed designed to place them on a firm footing, by giving them a legal status, permitting them to hold property, and to sue and be sued in courts of law. This act was repealed in 1829 and a new law passed, which has been succeeded by several others, the latest being that of 1875.

Of the English societies the Masons and the Odd Fellows are both largely represented within the United States. The first lodge of American Masons was organized in Boston in 1733, and in the following year one was instituted in Philadelphia, with Benjamin Franklin as its Worshipful Master. There are more Masons in the United States to-day than in any other country in the world, their strength here being over 600,000. The order of Odd Fellows was brought to America in 1819, when a lodge was founded in Baltimore by some members of the Manchester Union. It grew rapidly, and in 1842 the American branch cut loose from the parent society of Great Britain, in consequence of certain differences in their working rules. Since that period the society has flourished in the United States, and is strong numerically and financially at the present day, its membership in this country being over 600,000 with nearly 10,000 lodges.

In addition to the societies of English origin there are a considerable number of American institution, some of them of national importance. The Knights of Pythias was founded in Washington in 1864, its expressed object being "peace on earth and good will toward men," and to disseminate the "great principles of friendship, charity, and benevolence." It became a popular order and has grown rapidly, having in 1885 more than 2000 subordinate lodges and over 160,000 members. A society of earlier origin is the "Red Men," in whose lodge-meetings the customs and dress of the American Indians are simulated. This has not grown in later years as rapidly as some other societies, but is to-day in a prosperous condition. Another of the older American societies is the "Order of American Mechanics." Some societies of more recent institution, however, have surpassed in popularity those older ones, and notably "The Knights of the Golden Eagle," which has at present 281 "castles" or lodges in Pennsylvania alone. Of recent years the disposition to found new societies has been active, and many have come into being, among which may be named "The Knights of Malta," "The Senate of Sparta," "The Knights of the Mystic Chain," "The Legion of the Red Cross," "The Royal Arcanum," "The Brotherhood of the Union," "The United Workmen," "The Patriotic Sons of America," "The Knights of Friendship," "The Universal Order of Security," and "Order of the Iron Hall." This is not offered as a full list. Other societies could be named, while there are many which are as yet of local importance only. But in the list of important mutual aid societies of the United States must be included "The Grand Army of the Republic," an organization composed of the veteran soldiers of the civil war, and one that is worthy of the highest respect of the American people.

These various societies are differently constituted, and have different methods of beneficial procedure. In some, new members are examined by a competent physician; in others, the dues vary in accordance with the age of the member; in certain societies of recent origin benefit payments are made only in case of death, a sum being paid sufficient for the burial of the deceased member and the temporary support of his family. In these the members are assessed for dues only when the death of a fellow-member takes place, and the dues vary with the number of

deaths. These societies are conducted on the life insurance principle, and some of the older societies have adopted a similar principle, permitting their members to insure their lives for fixed sums by making payments in accordance therewith. One recent society which combines the payment of sick benefits with life insurance is that known as the "Iron Hall," whose working principle has been adopted by other organizations known as the "Order of Tonti" and the "Sexennial League." Numerous other societies, of local interest, might be named, all based on the useful principle of aiding their members in seasons of distress. Each new society seeks to afford the most help for the least payment, and it must be confessed that much progress has been made in the beneficial management of society funds.

In addition to the mutual aid societies organized expressly for charitable and insurance purposes, there are numerous associations which add to this aim others of equal importance. There are two particular classes of these societies, the labor unions and the temperance associations, both of which call for some consideration. With the growth of the factory system of labor, as we have already said, trade unions took the place formerly occupied by the guilds, which had long ceased to be vital organizations. The combination of working-men in opposition to capital began in England in the latter part of the last century, particular opposition being shown at that time to the introduction of new labor-saving inventions. There is no evidence that any such societies existed in America during the colonial period. Home labor was then the rule, and there were no large collections of mechanics in industrial centres. But by the opening of the 19th century the modern conditions of labor were well established, and the long conflict between labor and capital had begun. Something like a strike took place in New York in 1802, when the sailors of that port quit work to enforce an advance of wages from \$10 to \$14 a month. Organizations of labor appeared at the same time, beginning in local combinations of single trades. The New York Society of Journeymen Shipwrights was formed in 1803, and a society of House Carpenters in 1806. In 1817 the New York Typographical Society is spoken of as a strong institution. Yet up to 1825 there is little trace of such societies outside of the State of New York.

After 1825 labor showed a disposition to combine on a larger scale. The local unions increased in number, and the idea of national unions arose. The two cities most prominent in this movement were Boston and New York. In 1833 an address was made before "The General Trades Unions of the City of New York," the first indication we have of the effort to combine all the workmen of one locality. A premature attempt to form a national trades union was made in 1835, though with no definite result, and it was not till after 1850 that any efforts to organize national unions became successful. Of these the earliest was the National Typographical Union, traceable to 1850, but not permanently organized till 1852. In 1869 its name was changed to "The International Typographical Union," with the purpose of including the printers of Canada. This is the oldest American trades union now in existence, all the earlier ones having vanished. The hatters combined in 1854; the iron and steel workers in 1858; the iron moulders, and the machinists and blacksmiths, in 1859; and it is said that 26 trades had national organizations in 1860. These national unions were followed by the so-called international societies, most of which, however, are international only in name. In 1864 the Grand International Brotherhood of Locomotive Engineers was formed, and that of the cigar-makers in the same year. Societies of this national character were formed with

rapidity after that period, until to-day there is scarcely a distinct trade without such an organization.

The next step in the process of combination was the effort to form a national organization of all the trades. This was taken in 1866, when the National Labor Union was formed. It grew rapidly in numbers for a few years, and then declined and died out. A more successful effort was made in 1869. On Thanksgiving day of that year Uriah S. Stevens, a Philadelphia tailor, called a meeting which proved the initial step in the organization of the Knights of Labor, a society which in 19 years has grown into the most powerful labor organization of modern times. It differs from all previous labor societies in including all branches of skilled and unskilled labor in its organization, its expressed purposes being mutual aid of members, protection against the encroachments of capital, and the attainment of reforms in industrial relations. This society admits all men to membership except bankers, brokers, professional gamblers, lawyers, and liquor makers and sellers, and is the first of such societies to recognize the claim of unskilled labor to the same protection which skilled labor has so long possessed. Other general societies on a different basis have been instituted from time to time, constituting federations of labor unions, delegate bodies to which each subordinate union sends a representative. Such labor congresses now exist in all the large cities of the Union. In 1881 there was organized in Pittsburgh, on a national basis, a "Federation of Organized Trades and Labor Unions," on the model of the trade-union congress of England.

Just how many persons are included in these American trade societies is not known. It cannot be less than a million, and may be much more. In 1880, according to the Census Report, there were 2440 such societies in the United States, representing 132 industries. Of these one-quarter of the whole (620) were located in the State of Pennsylvania, while no other State had much over 200. This is a natural result of the great importance of Pennsylvania in the mechanical industries. The same State leads in benevolent and beneficial organizations—probably from the same cause. The societies above described, the strictly beneficial, and in some cases the labor associations, are often the only savings banks of working-men, being accident, sick, and life insurance companies in which the small weekly dues paid by the members are frequently their sole provision against future want. These dues are usually from 12 to 15 cents per week. The trade societies protect their members against reduction of wages and pay them benefits during strikes, thus serving a doubly useful purpose. In this connection it is necessary to mention the socialist societies which have gained so unenviable a reputation in recent years. Of these there are three in the United States: "The Socialistic Labor Party," "The International Working People's Association," and "The International Workmen's Association." It is the last named of these which has rendered itself so objectionable by its open advocacy of anarchical violence, and by the murderous use of dynamite as an exemplification of its principles. It is chiefly composed of the most turbulent element of European labor, disposed to put in practice here methods devised against the oppressive governments of their native soil, but in no sense applicable to American institutions. The others named are to some extent anarchical in their principles, but have not yet proved so in their practice. (See SOCIALISM.)

Of the remaining societies in which the mutual aid of members is a prominent feature, that of the Grangers, or Patrons of Husbandry, has been already treated (see GRANGERS). Its purposes are largely

social, but mainly protective, including the purchase of goods and machinery at producers' prices and mutual defence against railroad discrimination. We have yet to mention the temperance societies, in which a crusade against liquor is the principal feature, though in some cases combined with financial aid to members. The associated temperance movement began early in the century, and grew very active after 1825, but the existing orders of temperance did not come into being until 1842, when the "Sons of Temperance" society was organized. In the same year there was introduced into the United States an English society, "The Independent Order of Rechabites," which had existed since 1835. It spread with great rapidity in this country, and had at one time more than 100,000 members, but has now but a small fraction of that number. The Sons of Temperance grew with yet greater rapidity, and in 1850 had 232,233 members. It declined greatly during the civil war, but it is now growing again, and in 1888 numbered 78,913 members. It is a secret society, admits to membership women as well as men, and colored as well as white men, and is beneficiary in its workings. This pioneer society was followed in 1851 by the "Order of Good Templars," which left out the mutual aid principle, and made temperance reform its sole purpose. This society grew very rapidly, extended, like the Sons of Temperance, to England and other countries, and has lodges now in every country of the civilized world. In 1875 it had in all 735,000 members. Since then it has declined in numbers, its strength in 1888 being 483,103 members. Women are eligible to membership, and there is a juvenile branch having, in 1888, a membership of 139,951. Juvenile temperance has made great progress in other societies, as the "Cadets of Temperance," and the English "Band of Hope Union," which is said to have over 800,000 members in Great Britain and Ireland. Other American societies are the "Templars of Honor and Temperance," organized in 1845; the "Independent Order of Good Samaritans and Daughters of Samaria," organized in 1847; the "Royal Templars of Temperance," organized in 1869; and a considerable number of smaller societies of local interest only. Temperance societies exist in many churches, the most publicly prominent of these being the Catholic Total Abstinence Beneficial Society, which has done great good in its crusade against strong drink. Of recent societies, however, the most important is the Woman's Christian Temperance Union, which has been exceedingly active in the cause of temperance reform, and has very recently combined many of the juvenile temperance organizations into a single society, "The Loyal Temperance Legion," whose membership is estimated at 500,000. There are other temperance societies of recent organization, such as the "Law and Order Society," "The Reform Clubs," etc., but as these last-named societies do not belong to the beneficiary class they need not be further mentioned.

What has been above said is sufficient to show that the idea of association for mutual benefit has had a remarkable development in the United States during the nineteenth century, and that at present the membership of such societies includes a very considerable portion of our population. It might be shown also that these societies have made no less progress in their methods of beneficiary procedure, and the skilful handling of their funds, the experience of life insurance companies having proved highly useful to the mutual aid societies. As at present constituted, in fact, every degree of progress in this direction can be traced in the workings of the several societies. In the Free Masons, for instance, we have a retention of the mediæval general and non-obligatory system of charity. Other socie-

ties retain the early methods of sick benefits, while still others have introduced life insurance as an important feature of their beneficial methods, though the legality of this attempt has been seriously questioned. Others add to the mutual aid idea purposes of self-defence against the encroachments of capital, and of aggression against the liquor interests and the ravages of intemperance. The mutual aid feature of these societies is of the utmost importance and value to the industrial portions of our population, they forming, in a majority of cases, the only bulwark of their members against want in case of sickness and accident, and assurance of relief to their families in case of death. (C. M.)

SODA. Of all the chemical products used in human industries soda is far the most important, and the increase in its consumption has borne an intimate relation to the progress of civilization. Formerly, of the two salts soda and potash the latter was the more important, being most abundantly and cheaply produced. The chief source of soda at that time was the ashes of certain sea and sea-shore plants. In 1791 the Le Blanc process of producing carbonate of soda directly from common salt was perfected, and since then the use of soda has grown enormously. In this process salt is decomposed by the aid of sulphuric acid, and sodium sulphate or "salt cake" produced. Sodium carbonate is then produced by mixing the salt cake with limestone and charcoal, or small coal. This process has never been employed in America, except on a small scale. In 1866 Ernest Solvay, of Brussels, devised what is known as the ammonia process. In this a solution of bicarbonate of ammonia is mixed with common salt, and decomposes it, yielding a bicarbonate of soda precipitate and a solution of ammonium chloride. This process is growing in favor, and is employed in the soda manufactories now existing in the United States. Of recent years the American production of this substance has largely increased, though it is yet far below that of Europe. About one-fourth of the soda now used is made by the ammonia process. A factory employing this process was established at Syracuse, N. Y., in 1881, using the salt of the wells of that state, and has now a capacity of about 40,000 tons annually. Another factory has been recently started at Syracuse, to make fine sulphate of soda for glass-makers' use. Yet the soda used in this country continues to be in large part imported from England, the proportions being, in 1885, 167,093 tons imported to 15,000 manufactured. The importation of the various salts of soda in 1886 amounted to 368,766,594 lbs., while about 10 per cent. of this quantity was produced in the United States. In the manufacture of soda, it is interesting to observe how greatly the industry has been diverted from its original object. Soda, originally the only valuable product of the Le Blanc process, has now become but a by-product. The hydrochloric acid yielded in the process first became valuable through the growing demand for chlorine, and more recently the production of soda and chlorine have both become unprofitable, and the chief profit comes from the utilization of the process in the wet method of extracting copper from its ores. The growth of the ammonia process comes from the growing abundance and cheapness of ammonia, which is now obtained commercially from coke-ovens and from the gases of blast furnaces. It appears possible, indeed, to collect and utilize a portion of the nitrogen of nearly all fuels, and it has been suggested that the soda-maker shall cease to use raw coal as fuel, but coke it, collect for sale the oil and ammonia evolved, and use for heating the gases yielded in coking and the coke itself; thus obtaining his fuel virtually without cost.

The materials for making carbonate of soda are of unlimited abundance in this country, yet the cheapness of foreign labor has hitherto prevented successful competition. Soda is made in limited quantities at Philadelphia from the cryolite of Greenland, while caustic soda is manufactured somewhat largely in that city and elsewhere, though the main supply is still obtained by importation. Soda for baking-powders is also extensively produced in American factories. One San Francisco concern is manufacturing soda for this purpose from the native salts of Nevada, while great progress is making in the production of carbonate, bicarbonate, and other salts of soda from these western alkaline deposits.

These deposits are perhaps destined in the future to become the world's great source of soda. In the rainless region of the far west is a broad "alkaline belt" in many parts of which the earth is deeply impregnated with alkaline salts, principally those of soda, while there are many lakes whose waters contain a considerable percentage of soda salts, and in certain places crystallized soda occurs in thick deposits. This varies from nearly pure carbonate in some instances to chloride and sulphate in others, while the quantity is abundant beyond any possible demand. The alkaline belt lies in the least explored region of the United States, its lack of rain rendering it unfit for agriculture, while its prospectors are mainly in search of minerals, and pay little attention to its alkali beds. Yet some of these are coming into use as sources of commercial soda, and others are likely to do so with the development of railroad facilities of transportation. Up to a recent period the only natural deposits worked to any extent were those situated in the Carson Desert, Churchill Co., Nevada. Here there are two lakes, their beds evidently the craters of extinct volcanoes. The soil is saturated with soda, which is leached by the springs and streams flowing into the lakes, and, as the waters of these lakes evaporate during the summer, the soda is deposited in crystalline form. This crystalline mass, containing a considerable percentage of carbonate of soda, is collected, dried, and sent to market. Several smaller deposits in Nevada have been worked to some extent for the San Francisco market. The lakes in this region have no outlet, and all are more or less saturated with the alkaline leachings of the soil, which vary from nearly pure carbonate in some cases to sulphate and chloride in others. Large deposits of nearly pure sodium sulphate occur in Nevada near the California borderline, where the crystalline mass is said to be from 2 to 8 feet thick over an area of 100 to 200 acres.

Wyoming Territory possesses numerous small soda lakes, some of which are now worked for commercial purposes. About 13 miles nearly due south from Laramie City lie the "Union Pacific Lakes," to which a branch railroad has been extended. There are here five lakes, while the soil is everywhere impregnated with sulphate of soda. In wet years the soda in these lakes is almost fluid. In dry years, from large evaporation, it becomes solid in four of the lakes, and a saturated solution in the fifth. The soda of these lakes has been worked since 1885, over 60 tons of caustic soda being produced in that year. It being the sulphate salt, the first step in the Le Blanc process can be dispensed with, but the trouble and delay in getting rid of its abundant water largely negatives this advantage. The deposit is practically inexhaustible, it being now more than 9 feet thick over an area of more than 100 acres, and annually added to by the inflow from saturated springs. It is estimated to contain about 50,000,000 cubic feet of chemically pure sulphate of soda. The Donney Lakes, about 18 miles southwest of Laramie, comprise three lakes, covering about 520 acres. In one of these the deposit is 11 feet thick, in the others 5 to

6 feet. The Dupont Lakes in Carbon Co., Wyoming, are four in number, varying in area from 4 to 2000 acres, their waters saturated with sulphate and carbonate of soda. One of these lakes is covered by two claims, known as the New York and Philadelphia claims, the former including 160, the latter 80 acres. One bore-hole, sunk 50 feet from the shore, showed a bed of 4 feet of soda; another, 230 feet out, went through 14 feet of solid soda without reaching its bottom. This is over 70 per cent. sulphate of soda. The percentage of carbonate of soda is much greater in the Dupont than in the Donney and the Union Pacific Lakes, amounting, in some of the deposits made by evaporation, to 59.24 per cent. Near Morrison, Colorado, the soil, over an area of 80 acres, is impregnated with soda salts to a depth of 52 feet. There is another large deposit near Croton Springs, Arizona, where a thick bed of the several salts of soda covers an area of several square miles. Few of these deposits have been examined with a view to their utilization, the distance from railroads and high cost of transportation rendering them unavailable at present.

As for the uses to which soda is applied, they are manifold. One of the most important of these is the glass industry, which consumes about half the soda used in the United States. In 1885 the consumption in this industry was: Soda ash, 60,050 tons; salt-cake, 23,419 tons; nitrate of soda, 2987 tons; common salt, 2323 tons—making a total of 88,779 tons. The use of salt cake or sulphate of soda in this industry has largely increased of recent years, its percentage increasing from 14 in 1880 to 28 in 1885. Another large soda-consuming industry is the soap manufacture, while soda is an important requisite in paper making, in dyeing and bleaching of cotton and woollen goods, in boiler cleaning, etc. It is used in considerable quantities in the making of baking-powders, which now replace yeast in most American kitchens. Bicarbonate or sesquicarbonate of soda is an essential element of these powders, the purpose being to develop carbonic-acid gas in the interior of the dough, a result similar to that which is attained by the use of yeast. Soda bicarbonate is also used as one of the constituents of soda-powders and seidlitz-powders. These are but a few of the uses to which the salts of soda are put. They are used also in the starch, sugar, glucose, oil refining, candle, aniline dyes, wood-pulp, earthenware and pottery, dynamite, and many other industries, the number and diversity of which are sufficient warrant for the statement made at the beginning of this article that soda is far the most important chemical product used in human industries. (C. M.)

SOILS. Soils are the results of two active and incessant terrestrial influences, the disintegration of the rock materials of the earth's surface, and the deposit in the abraded material of organic substances, the product of animal and vegetable life processes, and of the decay of dead organic matter. To the former the great bulk of all soils is due; to the latter, much of their fertility. The breaking down of the rocks is a slow but incessant process. It is effected by the agency of rains and running water, of frosts and sunshine, of atmospheric action, and other less important influences; the small rock particles thus produced and scattered through the soil being gradually reduced to a finer stage by minor influences, among them the action of plant-roots and of the small animals which burrow in the earth's surface. The influence of earthworms, ants, and other small creatures upon the constituents and conditions of the soil has of late years been shown to be considerable and important. Organic materials are deposited in the soil largely by natural processes, and to an important extent through the agency of man. These in bulk constitute but a small percentage of the soil,

but their utility is far in excess of their quantity. Many of the most important food plants feed largely upon them, and exhaust them from the soil at a rate that requires their annual restoration. Human agency assists also in the making of soils by the addition of fertilizing mineral substances, such as lime, the mineral phosphates, etc., thus adding to imperfect soils some important element of fertility, or modifying the character of the soil so as to adapt it to the production of certain crops. Through these agencies of man and other animals, and through the disintegrating processes of nature, soils of greatly varied composition are produced, their character often changing considerably within a few miles of distance, and occasionally within the limits of a single farm.

Soils, considered in reference to their degree of openness and closeness, lie between two extremes, the sandy and the clayey. Their degree of fertility, however, does not conform to this division, the sandy soils, for instance, while frequently barren, being by no means always so, since the composition of sand may very greatly vary. The distinction of these two extremes is that of degree of comminution of material and retention of moisture, and of comparative permeability, rather than of fertility, the latter quality being by no means dependent on the above characteristics. Austere barrenness, as a rule, is confined to the silicious sands, and to rainless and streamless regions, there being scarcely any other condition of soil and climate that is not adapted to the free growth of plant forms. Of the sands and gravels that cover such vast spaces in the Eastern Hemisphere, the infertility is due rather to lack of rain than to native barrenness. The sands of the Sahara and of Arabia show no lack of fertility where watered by springs and wells. These vast stretches of sandy soil are paralleled in other parts of the earth by other homogeneous deposits of great extent. In Southern Russia, for instance, there is a vast tract, 200,000,000 acres in extent, of "black earth," which is of extraordinary and persistent fertility. In the highlands of Scotland and Bavaria, as also in Prussia and elsewhere, are great stretches of moorland, bearing only a nearly useless growth of heath or moss. In the United States we have similar great homogeneous surfaces, as in the alluvial bottom lands of the Mississippi, the compact, deep, widely extended soil of the prairies, the broad reaches of alkali lands in the western mountain region, the sands of New Jersey and some other localities, the vast swamp regions along the southern Atlantic coast, and other less extended instances. But as a whole, the soils of this country as of other regions are heterogeneous in distribution, depending largely upon the character of the underlying rock, and in many cases differing greatly within limited areas—clay, sand, gravel, vegetable mould, and unlike mixtures of these, occurring often in close proximity to each other.

The agencies and methods by which the hard rock surfaces are broken into fragments and ground down into soils, have been sufficiently considered in the article on *AGRICULTURE*, Chap. II., in this work, and we need here but consider some further aspects of the subject. There are two broad classes into which soils may be divided, the sedentary and the transported. Of these the sedentary soils, or soils in place, are those in which the materials of rock disintegration have not been moved by natural agencies, but remain where produced. They have arisen from the weathering of exposed rocks, which they still cover or lie contiguous to, and with which they are identical in composition. Such soils have usually little depth, their presence protecting the rocks which they cover from further disintegration. The inspection of the underlying rock usually gives valuable information as to their composition and agricultural

value, the mineral elements visible in it not being so readily observable in the finely comminuted soil. Soils of this character are not abundant in New England and the regions north of the Ohio, and east of the Missouri, nor in the river valleys of the country. Here they occur only in small patches, as where the friable outcropping red sandstone of the Connecticut valley has crumbled into soil, or where trap bluffs have made soils at their bases. In the more southern and western regions, away from the river valleys, sedentary soils are the rule.

Transported soils are those in which the material has been removed to a distance from its place of origin by moving agencies, principally ice and water, and deposited elsewhere as sediment. Of these those known as drift or diluvial soils are characterized by the rounded edges and surfaces of their larger fragments, and by their lack of stratification. They embrace soils proper and collections of stones, varying in size from grains to great rock boulders, which are scattered indiscriminately through and over the soil. These soils are supposed to be the product of ice action, the work of the great glacial movement which, there is satisfactory reason to believe, took place during the glacial age of geology, affecting the whole country from the Arctic zone to about the latitude of 40°, its effects on the soil extending to southern New England, to nearly the southern boundary of Pennsylvania, and to the Ohio River, and extending from the Atlantic to the States west of the Mississippi. The whole of this region is more or less covered with the rock débris moved by the glacier, the material being as a rule transported 20 to 40 miles from its place of origin, and in some cases from 60 to 100 miles. Drift soils are often of the most diversified character, including rock materials of great variety, which have been mingled and carried in the ice flow. Of those only the hard granite and silicious rocks occur in large fragments, the softer ones being ground to powder, the fine soil and stones of varied size being often indiscriminately commingled. Drift surfaces are usually irregular and hilly, the hills being conical heaps or long ridges of mixed sand, gravel, and boulders, often of great depth. South of the boulder line is a region, occasionally of considerable width, of much finer material, and partly stratified. This is supposed to have been the mud and sand carried by the waters of the melting glacier, and deposited by the streams over a broad area farther south. The sands of southern New Jersey and Long Island may have been due to this process, as well as the fertile soil of southern Pennsylvania. Drift soils greatly vary in productiveness, in consonance with their variety of materials. The soils of New England, for instance, are lacking in fertility, while those of Pennsylvania and Ohio are of unsurpassed excellence.

Another form of the transported soil is that known as alluvial. This consists of the worn materials transported by running waters, and deposited along the course of overflowing rivers. These are always more or less stratified, the coarser materials on the bottom, the finer on top. The coarser are also deposited most abundantly along the upper reaches of the rivers, the finer farther down, impalpable mud being carried much farther than sand or gravel. Such soils occur in the valleys of streams, and in silted-up beds of old rivers, lakes, and gulfs. In the United States, much the most extensive deposit of alluvial soil is that laid down in the bottom lands of the Mississippi River and its western tributaries, the Ohio cutting too narrow a channel to leave much space for such deposits. The bottom lands of the Mississippi, covered everywhere with finely comminuted materials abraded by the river and its tributaries from the head-water and bordering regions of the streams, and deposited along the more level

lower reaches of the river, average 40 miles in breadth, and extend for a distance of 500 miles, the stream winding through them with a length of 1,100 miles. Their total area is about 32,000 square miles, much of it of great depth of soil and almost inexhaustible fertility, though comparatively little of it is yet cultivated.

Soils in which drift and alluvial are mingled with sedentary materials, have been named colluvial soils. They are distinguished by the presence in transported material of sharp-angled fragments of original rock, that have evidently not been carried far. Such soils are of comparatively small extent. Of other distinctive American soils, may be mentioned those of the prairie States, which are distinguished by the absence of trees and the great depth of their fertile material. They probably belong to the alluvial class, being produced by the gradual silting up of great, shallow lakes, which formerly may have occupied this whole region. Their productive powers seem to be increased by the processes of cultivation, and seem almost inexhaustible, many years of cereal production without manuring showing little perceptible diminution in abundance of crops. In the western borders of the prairie region fertility is diminished by the lack of rain. In respect to its rainfall, the United States may be divided into two nearly equal portions by the meridian of 100°. The region east of that meridian has a sufficient and pretty regular distribution of rain; that westward is irregularly and insufficiently supplied, except a narrow belt on the Pacific coast. Part of the latter is abundantly supplied; part of it irregularly but in fair sufficiency; while in part of it the rain is insufficient for agriculture. Much of this region is, and must remain, essentially pastoral in its uses, though through a considerable portion of it irrigation has taken the place of rainfall, and abundant crops are raised from the highly fertile soil. The specially arid region of the United States is that known as the Great Basin, a vast district with an area of about 225,000 square miles, which constitutes an elevated plateau between the Rocky and the Coast mountain ranges, which, from its rainless character and the impossibility of irrigation, must remain permanently useless in an agricultural sense. (See GREAT BASIN.)

We may conclude with a brief consideration of the several varieties of soils, and their distinctions of physical and agricultural character. Plants derive their food from the fine, and particularly from the finest particles of the soil, of which a very small percentage is available for plant-food at any one time. But the larger particles are equally useful, from their aid in keeping the soil open and permeable, while through their gradual disintegration they furnish new plant-food. Gravelly soils are so named from their abundance of small stones or gravel. Such soils may be poor or rich, in conformity with the character of their fine material, and also the composition of their gravels. If there be many pebbles of felspar, the soil will probably be well supplied with alkali; if of limestone, with lime; if of quartz, the soil will be poor. Sandy soils are those which contain 90 per cent. or more of sand, or small grains of rock of any kind. If the sand be composed of nearly pure quartz grains, the soil will be barren, but generally other minerals, such as felspar and mica, are present, and iron compounds exist where the sand is red or yellow. These minerals, by their decomposition, often give considerable fertility. The green-sand of New Jersey is used as a fertilizing material, it containing much organic substance. The term sandy soil is, therefore, very indefinite as regards fertility. Coarse sandy soils are usually unprofitable, but fine sand is often agriculturally valuable.

Clayey soils, physically considered, stand at the

opposite extreme from sand. They are those in which clay or impalpable materials predominate. The extreme fineness and close compacting of their substance render them very retentive of water, which sandy soil is almost incapable of retaining, and when dry they break into cracks and rifts through shrinkage. Soils may be clayey in texture without being composed of clay, since other substances than kaolin and the other clay compounds may give them adhesiveness and impermeability.

Intermediate between clayey and sandy lie the loamy soils, or soils composed of a mixture of sand and clay, or of coarse and impalpable substances. These are less tenacious than clay, more so than sand, and exist in many degrees between sand and clay, being known by the various titles of clay loam, loam, sandy loam, light sand loam, etc. The physical condition of these soils is that best suited to ordinary agriculture. Calcareous or lime soils are those that contain carbonate of lime in predominating quantity. They are not uncommon in Europe, but are rare in the United States, and scarcely occur at all in the Northern and Middle States. In general, the lime is subordinate to sand or clay, yielding calcareous sands, calcareous clays, or calcareous loams. Marls are composed of a mixture of clayey material with finely divided carbonate of lime. The green-sand of New Jersey is of this character. Of other soils may be named peat or swamp muck, composed of humus arising from the decay of vegetable substance in bogs and marshes. Where much organic matter has decayed out of water, as leaves of trees, grasses, etc., it forms a soil of vegetable mould. Ochrey or ferruginous soils are those containing much iron oxide or silicate. They are yellow, red, or brown in color. The portion of the soil usually wrought is that near the surface, and which is directly exposed to sunlight, rain, and atmospheric influences, and which contains humus from decaying roots, etc. Beneath it lies the subsoil, unmodified by these agencies, yet often containing much fertilizing material. This is frequently brought to the surface in the deep plowing of recent farming. Under this, in certain regions, is a dense, almost impenetrable, crust known as "hard pan." It is composed of clay or gravel cemented by iron or other compacting material, and may be considered as soil on its way back to become rock. Hard pan often forms the bottom of marshes or peat-swamps, in a thin impermeable layer beneath which may lie porous soils. (C. M.)

SOLA, ABRAHAM DE (1825-1882), rabbi, was born in London, Sept. 18, 1825. He was carefully trained in Hebrew learning, and in 1847 accepted a call to a Portuguese-Hebrew congregation in Montreal. Here he became prominent as a pulpit orator and advocate of orthodox Judaism. In 1853 he was made professor of Hebrew in McGill University, and afterward lectured there on Spanish literature. He also taught Hebrew in the Presbyterian College of Montreal, and was president of the Natural History Society of that city. He died while on a visit to New York City, June 5, 1882. He published a *History of the Jews of Persia* (1848); *Scripture Zoology* (1848); *Jewish Calendar System* (1854); *Sanitary Institutions of the Hebrews* (1860); *Shabbatni Levi, the False Messiah* (1869); *History of the Jews of Poland* (1870); *History of the Jews of France* (1871).

SOLOMON, and the Book of PROVERBS. The author of the article on SOLOMON in the See Vol. XXII. ENCYCLOPÆDIA BRITANNICA speaks of p. 251 (p. 265 "the many floating and fragmentary Am. Rep.). notes of various dates that have found a place in the account of his reign in the Books of Kings." Dr. A. B. Davidson in the article on PROVERBS, in the same work, says of the times of Solomon, that "life in the civil sense began in this age.

. . . Then the tribes were consolidated into one community, the state rose into existence." One who holds that there was properly no Israelitish nation, and no united Israel, until the time of Solomon, and that the institutions described in the Pentateuch mostly originated during the successive centuries that followed Solomon, must necessarily hold that the history of Solomon, as given in the Bible, is disjointed and largely inconsistent with fact. But if we accept the statements of the Bible to the effect that Israel had been a people from the times of Abraham, and a nation from the times of Moses; that Solomon received from his ancestors the law that Moses wrote, the ark and tabernacle that Moses made, and the institutions that Moses founded; that the building of the temple was a fulfilment—up to that date, the most notable fulfilment—of the ancient promise to give Israel rest; that the religious ordinances and seasons of the Pentateuch, including the three great annual festivals, were observed in connection with the temple, in Solomon's time, then "the account of his reign in the Books of Kings" is consistent and intelligible. It presents itself as having been compiled from different sources, and as a record of only a part of the events of the times, but it is a coherent record.

On the whole, the accounts in Kings and Chronicles attribute to Solomon neither the highest type of moral and spiritual character nor the highest type of statesmanship. It is not likely, however, that his reputation as a builder, a man of culture, successful in commerce, and living magnificently, will ever greatly dwindle.

In the article PALMYRA, in the ENCYCLOPÆDIA BRITANNICA, Prof. W. Robertson Smith adduces considerations to show that the traditional reading of 1 Ki. ix. 18 is incorrect, that this passage does not mention Tadmor in the wilderness, and that the author of 2 Chron. viii. 4 is therefore mistaken in his reading of the passage in Kings. If these were conclusive they would go to show that Solomon's overland commerce was less extensive than has commonly been supposed. But they are not conclusive; they prove at most that the alleged understanding of the matter might be possible, if there were evidence in support of it, but they do not furnish the required evidence. For Solomon's purposes, the commercial route through Palmyra would not be a rival to that by the Red Sea, provided he controlled both routes, as the Biblical narratives certainly represent that he did. The opinion that Solomon founded Palmyra is more tenable than the conjecture that certain unknown Arabs founded it at some unknown later time.

For the times of Solomon in their relations to the rest of the history, see ISRAEL.

The Biblical accounts represent that there was a revival of literary culture in Israel in the reign of David, and that Solomon was especially distinguished in certain departments of science and letters. It is in accord with this that the Book of Canticles and most of Proverbs have been commonly attributed to him. In proof that Canticles is not an "unfriendly picture of Solomon," drawn by some northern Israelite, but is probably a genuine work of Solomon himself, see CANTICLES in this work. As to the Book of Proverbs, no one disputes that it contains some genuine sayings of Solomon. From the titles at the beginning of the book, and in x. 1 and xxv. 1, it is most natural to understand that the sayings here found are prevailingly (perhaps not exclusively) Solomonic; that chaps. i.-xxiv. are an earlier collection, including previous smaller collections; and that chaps. xxv.-xxix. are a supplementary collection of Solomonic proverbs, made in the days of Hezekiah. In extreme opposition to this, certain scholars hold the proverb-collections to be among the latest of the

post-exilic books. Differing from both these views, Dr. Davidson's article on this book holds that probably chaps. xxv.—xxix. are the oldest part of the book, and are a genuine collection made in Hezekiah's time by combining several earlier collections; that chaps. i.—ix were written "not very long anterior to the destruction of Jerusalem, possibly about a century after the men of Hezekiah made their collection;" that chaps. x.—xxii. 16, and the two smaller collections, xxii. 17—xxiv. are likewise, perhaps, pre exilic; and that xxx. and xxxi. are very likely post-exilic.

There is no reason directly connected with the question of the divine authority of the Scriptures to prevent our accepting views like these, provided they are well grounded; but the question whether they are well grounded is itself important. The grounds urged for them are such as the following: "The headings cannot be absolutely relied upon." It is sufficient to reply that there is no proof that the headings in Proverbs are unreliable. Dr. Davidson regards the heading in xxv. 1 as trustworthy, and observes that it presupposes the collection of proverbs in the previous chapters. Hence he infers that the heading cannot have been written by the men of Hezekiah who made the collection, but must have been added by the later editor who put the several collections together. The alternative inference is quite as probable, namely, that the heading was written by the men who made the collection, and that the collections in the previous chapters had then already been made. But it is said of these men: "They can hardly have been acquainted with x.—xxii., otherwise their code would not have contained so many duplicates of maxims in that collection." But, if these duplicated maxims prove that the first of the two collections was written later than the second, they equally prove that the second was written later than the first; that is to say, they prove nothing.

It is said that the general preface, at the opening of the book, "extends at least to xxii. 16; but . . . a new inscription 'The Proverbs of Solomon,' heads x. This implies that i.—ix. were not considered Solomonic." But this implication is not distinct enough to compel recognition from most minds. It is said that "the conjecture that Solomon himself put forth any collection of his proverbs has little to support it." But the conjecture that he did not put forth such a collection has still less to support it. It is argued that neither the whole nor any part of Prov. x.—xxii. 16 can have been collected in its present shape by any person who was the author of any great number of the proverbs contained in it, because the collection is confused, one of the proverbs being repeated, while there are several instances in which one member of a proverb also does duty in another proverb. But it is difficult to see that repetitions or confused arrangement are impossible for an author of proverbs any more than for any other man.

It is further said, in regard to Solomon: "Such maxims cannot be regarded as wholly or even in a very large degree the production of an individual mind. . . . Though the stream of wisdom began to flow in his day, its beginnings were then comparatively small; as the centuries advanced it gathered volume" But the Book of Proverbs is not a very extensive work, if compared, for example, with *Poor Richard's Almanac*, or with such a collection as might be made of the pithy sayings of Matthew Henry or John Bunyan. Why should not most of the proverbs have come from Solomon himself? Why should it require centuries to accumulate the rest?

It is also argued that the "universalistic ideas of God and providence," so characteristic of the Prov-

erbs, cannot have existed in Israel till the Israelites had come in "contact with the great empires of the world." But wide ideas of God and providence do not necessarily depend on contact with great political powers; and if they did, Israel's contact with these powers was as real at certain earlier periods as during the later invasions by Assyria and Babylonia.

The alleged proofs that Prov. xxx. is post-exilic are its likeness to Job xxviii. and Ecclesiastes, and the suggestion that ver. 6 may perhaps contain an allusion to "canonical writings." The proof that xxxi. is of late origin is that some of the products mentioned in this chapter are not mentioned in Ezek. xxvii. 17, and also that the alphabetic arrangement of the verses, beginning with ver. 10, is regarded as a late style of writing. Of course, none of these considerations have any decided strength.

On the whole, it is safe to affirm these two things in regard to the Book of Proverbs: Its contents are mainly Solomonic; the strongest evidence as to when the collections were made is that found in the titles, the order of the parts, and the presumption that a man like Solomon would have something to do with editing his own published works. (W. J. B.)

SOPHOCLES, EVANGELINUS APOSTOLIDES (1807–1883), classicist, was born near Mount Pelion, in Thessaly, March 8, 1807. He was educated in the convent on Mount Sinai, but afterward came under the influence of American missionaries at Athens. In 1829 he came to Massachusetts, entered Amherst College, and afterward taught Greek at Hartford and New Haven. In 1840 he was made a tutor at Harvard College, in 1849 assistant professor of Greek, and in 1860 professor of modern and Byzantine Greek. He was an excellent teacher, and rendered valuable service to scholarship in the United States by his grammars both of ancient and modern Greek, and various text-books. His most important work is his *Greek Lexicon of the Roman and Byzantine Periods* (Boston, 1870). In his modest apartments at Harvard he lived like a hermit, seeming to the youth of the Western Republic himself a picturesque fragment of the ancient civilization he strove to elucidate. He died at Cambridge, Dec. 17, 1883.

SORGHUM. See AGRICULTURE, Chap. V. 4.

SOULÉ, PIERRE (1801–1870), senator, was born at Castillon, France, in 1801. His father had been a lieutenant-general in the French republican army. The son was educated at Toulouse and Bordeaux. While at college in the latter city he joined in a conspiracy against the Bourbon government. On its discovery he fled, and concealed himself in the guise of a shepherd for a year. Going to Paris, he became a journalist, and soon was prosecuted and imprisoned for an attack on the government. He escaped to England, thence went to the West Indies, and soon removed to the United States. In 1825 he began his career at New Orleans, and was soon prominent as a lawyer and politician. He was sent to the U. S. senate in 1847, and there advocated extreme Southern views. In 1853 he was sent as U. S. minister to Spain, where his conduct was marked throughout with insolence to the government and his fellow-diplomats. He fought a duel with the French ambassador, encouraged a revolutionary outbreak, withheld a trade-treaty which had been negotiated, and joined in the Ostend manifesto which declared the purpose of the U. S. government to take Cuba, if not by purchase, then by force. He returned in 1855, and was interested in the Tehuantepec canal project. Though he opposed the secession craze in 1860, he went with his State, and in 1861 was a Confederate agent in Europe. In 1862 he was captured in New Orleans by the Union troops, and was sent to Fort Lafayette. Being released on condition of leaving the country,

he went to France, but in 1869 he returned. He died at New Orleans March 16, 1870.

SOUND. See **ACOUSTICS.**

SOUTHARD, HENRY (1749-1842), patriot and congressman, born on Long Island, N. Y., October, 1749, his father's name being Southworth. When he was but 7 years old, his father removed to Baskingridge, N. J., where, after receiving an ordinary school education, Henry worked on the home farm and as a day-laborer, till he earned money enough to purchase a farm for himself. An excellent memory and sound practical judgment fitted him for public work. He was active as a patriot during the Revolutionary war, was for nine years a member of the State legislature, and sat in Congress from 1801 to 1811, and from 1815 to 1821. In the latter year he met as a member of a joint committee of the U. S. senate, his son Samuel Lewis, and voted with him on the Missouri Compromise. Till he had passed his ninetieth year he neither wore glasses nor used a staff. He died at Baskingridge in June, 1842.

His son, **SAMUEL LEWIS SOUTHARD** (1787-1842), judge and senator, was born at Baskingridge, June 9, 1787. He received a sound education and graduated at Princeton College in 1804. After teaching school in his native State, he went to Virginia as tutor in the family of John Taliaferro, during his residence with whom he studied law, and was admitted to the Virginia bar. In 1811 he settled as a lawyer at Hemington, N. J., and in 1814 was appointed by the legislature law-reporter. In 1815 he became associate-judge of the supreme court of the State, was a presidential elector in 1820, and United States senator from 1821 to 1823, during a considerable part of which time he was *pro tem.* president of that body. In 1823 he was appointed by Pres. Monroe secretary of the navy, and held the office till 1829, acting also as secretary of the treasury from March to July, 1825, and for a short time as secretary of war. Immediately on his giving up the portfolio of the navy he was chosen attorney-general of New Jersey, and, in 1832, governor of the State. In 1833 he was again returned to the U. S. senate, and on Pres. Harrison's death, in 1841, he became for a second time president *pro tem.* of that body. In 1822 he was made a trustee of Princeton, and LL. D. by the University of Pennsylvania in 1833. He died at Fredericksburg, Va., June 26, 1842. His publications comprise, *Reports of the Supreme Court of New Jersey, 1816-1820* (2 vols., 1819-20), a *Centennial Address* (1832); and a *Discourse on William Wirt*. His son, **SAMUEL LEWIS SOUTHARD** (1819-1859), was born at Trenton, N. J., in 1819, graduated at Princeton, 1836, took orders in the Protestant Episcopal Church, and was author of *The Mystery of Godliness* (1848), and other theological and miscellaneous publications.

SOUTH BEND, a city of Indiana, county seat of St. Joseph Co., is on St. Joseph river, and on the Lake Shore and Michigan Southern Railroad and the Chicago and Lake Huron Railroad, 85 miles E. of Chicago. It has a fine court-house, 3 national banks, a savings bank, 20 churches, a high school, St. Joseph Academy, St. Mary's Academy, and the University of Notre Dame. Three daily and six weekly newspapers are published here. The manufactures comprise agricultural implements and machinery, wagons, furniture, paper, woollen goods, etc. Its population in 1880 was 13,280, having almost doubled in ten years.

SOUTHGATE, HORATIO, missionary bishop, was born at Portland, Maine, July 5, 1812. After graduating at Bowdoin College, 1832, he spent two years at Andover, but entered the Episcopal Church, and was ordained deacon at Boston, 1835. The Foreign Committee of the Board of Missions sent him abroad in April, 1836, to investigate the condition of Moham-

edanism in Turkey and Persia. After three years' absence he returned, and was ordained priest in New York, Oct. 3, 1839. The next year he was sent back as missionary at Constantinople and delegate to the Oriental churches, remaining four years. From these experiences came his first books, *Narrative of a Tour through Armenia, Kurdistan, Persia, and Mesopotamia* (2 vols., 1840), and *Narrative of a Visit to the Syrian (Jacobite) Church of Mesopotamia* (1844). On Oct. 26, 1844, he was consecrated in Philadelphia as missionary bishop for the dominions and dependencies of Turkey. [This was the only case in which the American Episcopal Church sent a bishop to lands having native clergy of that order, and it was afterward regarded as a step of doubtful wisdom.] In 1849 Dr. Southgate came home and offered his resignation of the office, which the House of Bishops accepted in October, 1850. He published, in Greek, at Constantinople, *A Treatise on the Antiquity, Doctrine, Ministry, and Worship of the Anglican Church*, 1849. He declined the bishopric of California, 1850, and that of Hayti twenty years later. He organized St. Luke's Church, Portland, Maine (now the cathedral), 1851, was rector of the Advent, Boston, 1852-58, and of Zion, New York, 1859-72. Since then he has lived at Ravenswood, L. I. His later books are, *The War in the East* (1855); *Parochial Sermons* (1859); and *The Cross above the Crescent* (1877).

SOUTH MOUNTAIN AND ANTIETAM. These battles were fought on Sept. 14 and 17, 1862, between the Union forces under Gen. McClellan and the Confederates under Gen. Lee, near the village of Sharpsburg, on the banks of the Antietam Creek, Maryland. After defeating the Union Gen. Pope in the second battle of Bull Run, Aug. 30, 1862, Gen. Lee in the beginning of September crossed the Potomac into Maryland, with the immediate objects of gaining over that State to the Confederacy and capturing Washington and Baltimore. Pres. Lincoln instantly called on Gen. McClellan (who was then in Washington) to take command of the Army of the Potomac, with which Pope's forces had been merged, and the general forthwith set his troops in motion to meet the inroad. On his arrival on the 12th at Frederick, which Lee had left three days previously, he came into possession of the latter's plan of campaign, which, with the view of leaving no enemies in his rear, comprised an order for Jackson to recross the Potomac, capture the forces at Martinsburg, and co-operate in the capture of those at Harper's Ferry; for McLaws to march on Harper's Ferry; and for Longstreet to halt with the trains at Boonesboro'. Walker was to invest Harper's Ferry from the Maryland side, while D. H. Hill's division was to form the rear-guard. On learning Lee's plans, McClellan set about a movement to pass his army through Turner's and Crampton's Gaps in South Mountain, and, by interposing it between the separated divisions of Lee's force, to destroy them in detail. But McClellan was, as usual, not sufficiently prompt, and when the Union army reached the gaps it found them beset by Confederates under Longstreet, Hill, and McLaws. There was stubborn fighting all day of the 14th; in the evening the Confederates withdrew, and next morning the victorious Unionists passed through the gaps to the western side of the range. But Lee, by delaying the Union advance, had gained time to concentrate his dispersed forces and to capture Harper's Ferry, with 11,000 men and 73 guns.

When Lee withdrew his left from Turner's Gap he took up an elevated position between the Antietam and Sharpsburg. His right, under McLaws, on the capture of Harper's Ferry, came promptly into line, and on the 16th Lee had his army concentrated there to the number of 40,000 men—a force ragged, indeed, and shoeless, and reduced by strag-

glers revelling in an unwasted region; but resolute, injured to war, and confidently awaiting the contest that it knew to be decisive of the campaign, in a position chosen by its leader. McClellan's army numbered over 70,000, but the Confederate army was protected on both flanks by the Potomac, on which they rested respectively, while the Antietam flowed along its front, the ground consisting of meadows, corn-fields, and patches of forest. The creek was crossed by four bridges, all save the northernmost strongly guarded. McClellan's plan of attack was to throw his right over the unguarded bridge upon the enemy's left, and, when he had thus drawn their main force to that flank, to cross with his centre and left and fall upon the enemy's right. Toward evening Hooker led his corps across the upper bridge, but little more than a skirmish ensued till the lines rested. He had, however, developed McClellan's plans and thus given Lee time to make his dispositions to meet it. The only change he thought it necessary to make was to place Jackson's fresh troops in the position on his left. McClellan during the night sent Mansfield's corps across the creek to join Hooker and had Sumner in readiness to follow in the early morning.

The dawn of the 17th saw the two armies standing ready for a great conflict in which there could be no strategy, but which must be decided by sheer fighting. The battle began at sunrise in the woods bordering the Sharpsburg road to Hagerstown by an attack by Hooker on Jackson's position in front, which was also enfiladed by artillery from across the creek. Jackson's lines at length broke, but when Hooker attempted to follow he was met by masses of troops and artillery fire, and forced to halt. Mansfield was mortally wounded when advancing to support him, but his corps moved on. Hooker himself was severely wounded and borne from the field. Sumner's corps came next on the field, and with comparative ease drove back the half-defeated Confederate divisions, and took possession of the ground they had held around a little Dunker church. His whole line now moved forward as if to sure victory, when two divisions brought from the Confederate right wedged themselves into a gap in his lines. Sedgwick's division, which formed the right of the line, was flanked on its left and driven out of the woods across the clearing into the eastern woods. The Confederates, satisfied with this, failed to pursue farther but retired to their position. Fighting of a similar character went on all forenoon. One striking episode was a race between a New Hampshire and Confederate regiment for the occupation of a commanding piece of ground, the two running in parallel lines and firing at each other as they ran. The New Hampshire men won the prize. Franklin did not participate in the fight till noon, having just then arrived from the southern (Crampton's) gap of South Mountain, and was at once despatched across the creek to aid Hooker. He came just in time to check an advance of fresh troops from the Confederate right.

But while both parties thus strove gallantly on the Union right, Porter and Burnside, in command of the centre and left, remained unaccountably supine. So early as 8 A. M., the latter had been ordered to carry the bridge on his front and assail the Confederate right. Though the command was more than once and urgently repeated, he did not succeed in crossing till 1 P. M., and, even after effecting this, two more hours were lost before he carried the ridge commanding Sharpsburg and captured the enemy's battery there. Then A. P. Hill's division, 2000 strong—Lee's last reserve—came up from Harper's Ferry and, uniting with the Confederate forces on the left, retook the battery and drove Burnside from the height. This concluded the battle. The strug-

gle ceased, not because a victory had been won, or because night had fallen, but because both sides had suffered so severely that neither was disposed to renew it. The reason why the Unionists, with their vast superiority in numbers, failed to carry a great victory is self-evident. The corps commanders, or, rather, some of them, did not act in concert, and the attack was made in dribbles. The Union preponderance in force was thus neutralized. At any one point Lee was able to meet an attack with a force as strong as that making it.

Gen. McClellan reported his entire loss at 12,469, of whom 2010 were killed; Lee's may be set down at 13,533. McClellan says "about 2700 of the enemy's dead were counted and buried upon the battle-field." Three Confederate generals were killed and 8 wounded. Of regimental and brigade losses may be cited that of the 16th Connecticut (which here saw service for the first time), which went in 940 strong and came out 508, and that of McLaws' Confederate brigade, which went in with 1150 men and came out with 596, losing 5 out of its 6 regimental commanders. Hay's brigade lost even more in proportion. McClellan reported over 6000 prisoners taken, 13 guns, and 39 flags, while he himself had not lost a gun or a color.

Sept. 18th, there was no fighting, and when, on the 19th, McClellan prepared to renew the struggle he found that Lee had left the field and withdrawn into Virginia by the ford at Shepherdstown.

(J. H.)

SPALDING, MARTIN JOHN (1810-1872), Roman Catholic archbishop, was born in Marion County, Ky., May 23, 1810. He graduated at St. Mary's College, Lebanon, Ky., in 1826, studied theology, and went to the Propaganda College in Rome. He was ordained priest in 1834, and was made pastor of the cathedral at Bardstown. In 1838 he took charge of St. Joseph's theological seminary there, and in 1840 he removed to Lexington, Ky., but in the next year returned to his original post. In 1848 he was made coadjutor to Bishop Flaget of Louisville, and in 1850 succeeded to the bishopric. While coadjutor he introduced some religious orders, and while bishop built a handsome cathedral at Louisville. He attended the plenary council at Baltimore in 1852. In 1864 he was promoted to be archbishop of Baltimore, and he died there, Feb. 7, 1872. Archbishop Spalding was noted for his literary activity. In 1835 he began to publish the *Catholic Advocate* and was connected with it till 1858, when he established the *Louisville Guardian*. His review of Dr. Merle D'Aubigné's *History of the Reformation*, issued in 1844, was enlarged into a *History of the Protestant Reformation* (2 vols., 1860). He also published *Early Catholic Missions in Kentucky* (1846); *Evidences of Catholicity* (1847); *Life of Bishop Flaget* (1852); *Papal Infallibility* (1870).

SPARKS, JARED (1789-1866), noted for his services to American history, was born at Willington, Conn., May 10, 1789. After getting a common school education he worked on a farm, then learned carpentry, and at times taught school. His eagerness to learn procured him friends, especially among the ministers, who helped him forward in pursuit of knowledge. At the age of 20 he entered Phillips' Exeter Academy, and two years later went to Harvard College. Though his student-course was interrupted by teaching in Maryland, where he also saw service in the militia against the British invasion, he graduated in 1815. Again he taught school at Lancaster, Mass., and then returned to Harvard to study theology. In 1817 the college authorities made him a tutor in mathematics and natural philosophy, and he also assisted in editing the *North American Review*. In May, 1819, being now thirty years of age, he was ordained pastor of a Unitarian church in Baltimore,

Dr. Channing preaching on the occasion. An earnest defender of Unitarianism, he engaged in animated controversies with Dr. Wyatt of the Episcopal Church and Dr. Samuel Miller of the Presbyterian Church. In 1821 he was chosen chaplain of Congress, but two years later ill-health compelled him to abandon preaching. After travelling through the Western States he settled in Boston, and there became editor and proprietor of the *North American Review*. While in Baltimore he had been industrious in writing, editing, and compiling, but rather on religious topics. He now turned to American biography and history, his first publication being a *Life of John Ledgard* (1828), though he had already been working on his edition of the *Writings of Washington*. This work, as finally published in 12 volumes (1834-37), contained both official and private papers, with notes, illustrations, and biography. Its value was attested both by elaborate reviews and by its republication in abridged form in England, France, and Germany. Its accuracy has been assailed, but on insufficient grounds. It must be understood, however, that Sparks did in some instances modify not only the spelling but the language of the original further than would now be thought proper. Before this work had appeared, Congress had authorized Sparks to edit the *Diplomatic Correspondence of the American Revolution*, which appeared in 1829-30 in 12 volumes. Another valuable work was his *Life of Gouverneur Morris* (3 vols., 1832). After this, calling to his aid a number of literary associates, he projected his *Library of American Biography*. The first series of 10 volumes appeared between 1834 and 1838; the second, of 15, between 1844 and 1848. Of the sixty lives here presented Sparks wrote eight: Ethan Allen, Benedict Arnold, Father Marquette, De la Salle, Count Pulaski, John Ribault, and Gen. Charles Lee. Meantime his edition of *The Works of Benjamin Franklin* (10 vols., 1840) had taken its place by the side of his *Writings of Washington*. Over 250 letters contained in it were printed for the first time. Another companion work was *The Correspondence of the American Revolution* (1854), which contains the letters addressed to Washington by nearly two hundred of his eminent contemporaries. Dr. Sparks had been in 1839 made McLean professor of history in Harvard College, and in 1849 was made president of that institution. In 1853 he was compelled to resign on account of ill-health. He continued to reside at Cambridge and was engaged on a *History of the American Revolution* until his death, March 14, 1866. Rev. George E. Ellis, D.D., published his *Memoir* in 1869. His library and manuscripts are in possession of Harvard University.

SPEAR, SAMUEL THAYER, Presbyterian editor and author, was born at Ballston Spa, N. Y., March 4, 1812. He studied both medicine and theology, and was ordained in 1835 pastor of a Presbyterian church at Lansingburg, N. Y. In 1843 he removed to Brooklyn, where he held a pastorate until 1870. In 1887, on account of infirmities of age, he retired from the Brooklyn Presbytery. He was for many years one of the editors of the *Independent*, and he also contributed to various reviews. Among his works are *Family Power*; *Church and State*; *The Bible Heaven*.

SPENCE, HENRY DONALD MAURICE, English clergyman, was born in Pall Mall, London, in 1836. He was educated at Westminster School and at Corpus Christi College, Cambridge, graduating in 1864. He was made professor of modern literature in St. David's College, Lampeter, in 1865, and rector of St. Mary de Crypt, Gloucester, in 1870. He also became principal of the Theological School of Gloucester and canon of the cathedral in 1875. He was made rural dean of St. Pancras in 1877. He has been noted for his exegetical labors. With Dean Howson he prepared a *Commentary on the Acts of the*

Apostles. He assisted in Bishop Ellicott's *Commentaries*, and was editor of the *Pulpit Commentary on the Old and New Testaments*. He has also prepared some treatises on the *Talmud*.

SPENCER, AMBROSE (1765-1848), jurist, was born at Salisbury, Conn., Dec. 13, 1765. He graduated from Harvard University in 1783, studied law, and began practice at Hudson, N. Y., where he was appointed city clerk in 1786. In 1793 he represented Columbia County in the State assembly, and from 1795 to 1802 he was a State senator. In 1796 he was appointed assistant attorney-general of Columbia and Rensselaer counties, and in 1802 was made attorney-general of the State. In 1804 he was raised to the bench of the supreme court, and from 1819 till 1823 was chief justice, being also meantime a member of the State constitutional convention of 1821. On resuming the practice of law, in Albany, he held various local offices, including that of mayor of the city from 1824 to 1826. Elected to Congress in 1829, he used his efforts to arrest the injustice of the government toward the Cherokees. In 1839 he retired to Lyons, N. Y., where he occupied himself mainly with agricultural pursuits. In 1844 he was president of the Whig national convention at Baltimore. He was author of a measure for abolishing capital punishment in all cases except treason and murder, and of another authorizing the erection of a State prison near New York City. He died at Lyons, March 13, 1848. The degree of LL. D. had been conferred on him both by the University of Pennsylvania and by Harvard College.

His son, JOHN CANFIELD SPENCER (1788-1855), jurist, was born in Hudson, N. Y., Jan. 8, 1788. He graduated at Union College in 1806, and in 1807 became private secretary of Gov. Tompkins. In 1809 he was admitted to the bar at Canandaigua, and in 1811 became master in chancery. He was appointed in 1813 judge-advocate-general in the army on the northern frontier, and in 1815 assistant attorney-general for Western New York. From 1817 to 1819 he represented his district in Congress; in 1820-21 he was a member of the State assembly, in the former year serving as speaker. From 1824 to 1828 he was a State senator, serving in 1827 as a member of a board for the revision of the statutes of New York. He was appointed special attorney-general to prosecute the murderers of William Morgan (see ANTI-MASONRY), but resigned in May, 1830. From 1839 to 1841 he was secretary of state and superintendent of common schools. In October, 1841, he was appointed secretary of war under Pres. Tyler, and in March, 1843, was transferred to the treasury department. He resigned office in May, 1844, owing to his opposition to the annexation of Texas. He then returned to the practice of his profession. He served on many State commissions. New York was largely indebted to him for the organization of its asylum for idiots and the improvement of its common school system. From his *alma mater*, Union College, of which he was made a regent in 1840, he received, in 1849, the degree of LL. D. In 1838, he edited, with a preface and notes, De Tocqueville's *Democracy in America*. He died in Albany, May 18, 1855. A painful and deplorable event in his family cannot be omitted. While he was secretary of war his son was a midshipman on the naval school-ship Somers, commanded by Capt. A. S. Mackenzie. While off the coast of Africa the midshipman headed a mutiny, but the mutineers were overpowered and brought to trial before a council of officers. In accordance with their sentence Spencer and two others were hanged at the yard-arm, Dec. 1, 1842. Capt. Mackenzie's conduct was subsequently approved by a board of inquiry.

SPENCER, HERBERT, an eminent English philosopher, whose system, based on the facts and theoret-

ical views of modern science, is still in process of development and publication. Spencer was born on April 27, 1820, at Derby, England. His father was a teacher of mathematics at that place, and a man of wide culture and marked character, and by his frequent discussions on radical social questions with his brothers, men of the same type, did much to develop the growing spirit of inquiry in his son. The tendency to scientific study in the boy was early shown in a fondness for keeping insects and watching their transformations, and for years the seeking and rearing of caterpillars, and the catching, pressing, and drawing of winged insects were his regular occupations. He assisted his father also in physical experiments. At the age of 13 he was sent to study with his uncle, Rev. Thomas Spencer, rector of the parish of Hinton. Here he remained for three years, making special progress in mathematics. Returning home he studied perspective with his father, and at the age of 17 was articled to a civil engineer, and was employed on the London and Birmingham Railway. In 1841 he returned home and spent two years in study, during which he collected botanical specimens, practised drawing and modelling, and showed strong inventive inclinations, manifested by improvements in the arts of watchmaking, type manufacture, etc. In 1843, after some attempts to obtain literary employment in London, he returned to engineering labors. But the railroad-building mania which had long prevailed suddenly abated, and the demand for engineers fell off.

Spencer's earliest essay in literature was in the form of professional papers contributed to the *Civil Engineer and Artisan's Journal*; but his career in this direction fairly began in a series of letters "On the Proper Sphere of Government," which appeared in the *Nonconformist* in 1842. The influence of the debates to which he had listened in his boyhood, and his own reflections on similar subjects, had given him decided and radical opinions on the nature and limitations of civil authority, which were indicated in these articles. His theory was that the governmental function should be limited to the protection of life, property, and order, the settlement of the general relations of society being left to individual social action. These letters were reprinted in pamphlet form, and constituted the basis of his later published views on the same subject, in which he has persistently advocated the contraction of the sphere of government and the leaving of the principal questions of social science and political economy to outwork themselves under the influence of natural law and without governmental interference. He believes that all wrongs will right themselves if left alone, and that political tinkering but checks the growth of true remedial influences.

Spencer, soon after ceasing the practice of his profession, took up his residence in London, and from 1848 to 1852 was engaged in literary work on the *Economist*, the *Westminster Review*, and the *Edinburgh Review*. At the house of the editor of the *Westminster* he met G. H. Lewes and Miss Evans ("George Eliot"), both of whom became his lifelong friends. In 1851 appeared his first important work, *Social Statics, or the Conditions Essential to Human Happiness Specified and the First Developed*. This remarkable essay advocates a theory of society widely different from any prevailing one. It is full of radical and original views, and, while following the line of argument of his pamphlet of 1842, is a far more complete and well-digested study of social science. It is still widely popular, especially in America, and though it does not fully represent the author's later views, and is probably impracticable in many of its suggestions, it remains a most valuable text-book of democratic political philosophy.

In 1855 appeared from his pen another work of great originality and value, *The Principles of Psychology*, a philosophical endeavor to analyze the relations between mind and matter, in which he first showed his strong inclination to the hypothesis of evolution. His thoughts had been led in this direction by his studies of social law, his writings on which are full of evolutionary conceptions. As his views took a wider range than the theory of society, he began to look upon the whole development of nature from an evolutionary stand-point, and gradually to organize in his mind that philosophy of evolution which it has been the work of all his later life to develop. According to his view old cosmological and scientific ideas were giving way and others taking their place, and it was evident that science must be reconstructed on a broader and more general basis than had satisfied the minds of preceding thinkers. The idea of the unity of nature and the interdependence of the sciences was steadily growing, and several writers had advocated the developmental hypothesis as applied to the world of animals. The mind of Spencer was full of this new philosophy, which shows its influence in everything he wrote. The period from 1850 to 1860 was with him one of great mental activity, during which he produced numerous review articles in addition to his published volumes. Among these were essays on "The Philosophy of Style;" "Manners and Fashion;" "Progress, its Law and Cause;" "The Development Hypothesis;" "The Theory of Population," "The Genesis of Science," "The Nebular Hypothesis," etc. These papers have been republished in the United States in several volumes, entitled *Illustrations of Universal Progress; Essays, Moral, Political, and Aesthetic; Education: Intellectual, Moral, and Physical; and Recent Discussions*. They all show the evolutionary tendency of his thoughts, which were steadily advancing to the conception of evolution as a universal law and the sole principle of development in the universe. In his *Principles of Psychology* he dealt with the mind in all its manifestations as a product of development, holding that as the body was evolved by insensible stages from the germ to the complex organism, so was the mind. He took the ground that the mental faculties have gradually developed through the whole range of animal life, under the influence of experience and the long-continued moulding of enviroing nature. This was the first attempt to apply the theory of evolution to psychological phenomena. Spencer's step forward was a bold one, which met with but little acceptance from zoölogists, and was decried by the world at large. The doctrine has won a much wider audience since then, however, Spencer's views having been adopted by several succeeding writers on psychology, while many students consider the *Principles of Psychology*, as finally revised, his greatest work.

By 1858 Spencer had completed his mental study of the principle of evolution as applied to the phenomena of nature, and had fully outworked in his thoughts the conception that evolution is a universal process, dependent on the laws of matter and force, and affecting and controlling all that takes place in nature, from the genesis of the atom to that of the human soul. In this year appeared his treatise on *The Nebular Hypothesis*, and while writing it his views of evolution unfolded till it expanded in his mind to a universal law, while all branches of knowledge appeared to him to be mutually dependent, and to be underlaid by this single principle. These views were not reached, like those of Darwin, through original scientific observation. Spencer's early tendency to scientific study made but little progress, and he did not become a specialist in any branch of science. Yet through persistent reading he became

deeply versed in the general facts and philosophy of the sciences, the biological branches in particular, and stored his mind with a much greater mass of data than he could have gained by original observation.

This course of widestudy and independent thought next led to the resolution of developing a new system of philosophy, with the principle of evolution as its underlying basis and the discoveries of modern science as its supporting walls and columns. In 1859 he drew up in detail the plan of a series of works in which his philosophical system was to be embodied. This plan embraced ten volumes, to the completion of which he proposed to devote twenty years. It included studies of the principles of nature considered generally, and in their special application to the phenomena of life, of the mind, of society, and of ethics, the whole subject being elaborated at this early period in the author's thoughts, divided into topics, and projected in the prospectus published in 1860 almost precisely as it has been carried out in his subsequent works. He saw it all at a glance. It has taken half a lifetime to explain it to the world.

Spencer's prospectus appeared in the same year as Darwin's celebrated contribution to the evolutionary hypothesis, and the view which many entertain, that Darwin devised this hypothesis and that Spencer has but unfolded and applied it, is utterly incorrect. Darwin lays no claim to the authorship of the theory of evolution. What he did was to advance the "natural selection" hypothesis of development, a principle which has been widely adopted by scientists, and which Spencer has made much use of in his striking phrase "survival of the fittest." But his philosophy was fully developed in his mind, and partly in his writings, before Darwin had published a word on the subject, though unquestionably the hypothesis advanced by the latter author has been utilized by Spencer in the explication of his philosophical idea.

The first volume of the projected system was published in 1862, under the title of *First Principles*. It is divided into two parts: 1, "The Unknowable;" and, 2, "The Laws of the Knowable." In the first part the author maintains that human knowledge has its necessary limits, beyond which it can never advance, and that there is an unknown power which must remain forever beyond the reach of man's conceptions. To this power he gives no name and says nothing as to its possible intelligence or non-intelligence, declaring that its qualities, conditions, and relations are utterly beyond the grasp of human thought, and that speculation concerning them is and must forever remain idle. This doctrine of the "unknowable" is not an essential part of his system of philosophy proper. It has been strongly combated, and some of its conclusions seem invalidated. In the "Laws of the Knowable" Spencer lays down the basic principles of his system as applicable to the general phenomena of matter, motion, and force, declaring that in all the details of nature a law of gradual development has steadily acted, all things advancing step by step from the general to the particular, from the unconditioned to the conditioned, until, from a simple, homogeneous, uniform, and generalized state of the universe, there has arisen, through evolutionary processes and solely under the influence of natural laws and forces, a complex, heterogeneous, multiform, and specialized state. To illustrate his theory in simpler form, the original diffused and homogeneous fire-mist of the planets has become developed into spheres of extraordinary diversity of conditions, matter having lost its original uniformity, and become the wonderfully varied combination of mineral, plant, animal, intellectual, and moral conditions which now exist upon the

earth's surface. It may be said here that Spencer uses a phraseology which renders the comprehension of his system very difficult to many readers; that it is by no means presented in the simplicity of which it was susceptible.

In *The Principles of Biology* (2 vols., 1867) the evolutionary hypothesis is applied to, and illustrated by, the facts of animal and vegetable life. In 1873 appeared *The Principles of Psychology* (2 vols.), in which the evolution of mentality is reviewed and illustrated. This work is in great measure an outgrowth of his treatise of 1855, being in some respects a second edition of that work, though with much expansion and a broader grasp of the principles advocated. Continued ill-health, which has grown more disabling of recent years, together with much writing aside from his main purpose, has prevented Spencer from completing his work within the twenty years originally allotted. Of the *Principles of Sociology*, but two volumes of the requisite three have appeared; while the *Principles of Morality*, designed to be in two volumes, is at present partly represented by a treatise entitled *The Data of Ethics*. In the former of these the laws of society are sought to be deduced from the facts of social and political science, while the latter seeks to deduce the laws of human conduct from man's relations to nature and his fellows, and the scientific investigation of the growth of the sense of duty, conscience, and moral obligation.

The completion of this work has also been delayed by the general prejudice against the author's views, while yet he was obliged to make a living by his pen. As no publisher could be readily found for the work when first proposed, the author decided to become his own publisher, and to issue the work in quarterly parts by annual subscription. The volumes, as they appeared, met with strong opposition and much adverse criticism, their views of nature being so radically unlike those before prevailing as to disturb all the relations of preceding philosophical and religious thought. Spencer, however, has gradually gained a large following, and in the quarter-century that has passed since the publication of the first volume of the series, there have been remarkable changes of general opinion upon the deepest subjects of human contemplation. These changes have undoubtedly in very considerable measure been due to his philosophy, and to the scientific theories of Darwin, with the concurrent views of numerous later authors.

All that Spencer has written since the publication of his prospectus bears somewhat directly on his evolutionary system. Of these separate works, *Education: Intellectual, Moral, and Physical*, a series of reprinted papers, written in a style of unusual ease and fluency for him, has been one of the most popular. In opposition to the old system of teaching by rote, it advocates methods in which the curiosity of the pupil is excited, his observation strengthened, and his judgment constantly appealed to. This was indeed the method of teaching employed by Spencer's father, and under which his school life was passed, and he was well aware of its efficacy from boyhood. Since the appearance of his work a steady improvement has taken place in educational methods, both in England and the United States, in the direction which he points out. To this improvement his work has undoubtedly contributed, though other influential writers took part with him in advocating radical changes in education.

Of his other publications may be named *Classification of the Sciences* (1864), in which he states his reasons for dissenting from M. Comte; *Spontaneous Generation, and the Hypothesis of Physiological Units* (1870); *The Study of Sociology*, in the "International Scientific Series" (1872); and *The Coming*

Slavery (1884), a bitter attack on the increasing tendency to socialism. Much of the time taken up in writing controversial articles might have been applied to the completion of his system, leaving it to fight its own battle, on its merits or demerits, against the attacks of opponents. In addition to these he has written many magazine papers, bearing on various points of his system.

Of his separate works, however, much the most important is his *Descriptive Sociology*, which was designed to be a complete repertory of facts in relation to the structure, habits, beliefs, and other conditions of society, of all grades and characters, ancient and modern, savage, barbarous, and civilized; these facts to be arranged in tabular form, for easy comparison and reference. The plan as laid out involved immense labor, far beyond his own powers and opportunities, and he engaged three assistants, adapted by their culture and information to the work. The original plan proposed a work in 18 parts, of which several have been published, including No. 1, a descriptive sociology of the English civilization; No. 2, the extinct American civilizations; No. 3, the Negrito and Malay races; No. 4, the African races, etc. The restricted sale of the work and the great expense of the undertaking forced him to limit it to 9 numbers, extensive unpublished materials remaining in his hands. This work, covering a wide range of social facts, is of great value so far as it goes, and its completion in accordance with the original design would make it an invaluable work of reference, replete with facts of sociology nowhere else to be found in such completeness and convenience of arrangement.

It is not our purpose to attempt any critical review of the great work of Spencer's life, his system of philosophy. It has called forth a vast array of critical opinions, favorable and unfavorable. It has been proved by later investigation that some of the supposed facts on which his arguments were based are not facts at all; certain of his positions have been invalidated; several of his theories are very unlikely to be accepted, much of his reasoning has been met by equally cogent counter-reasoning. Yet all these are but attacks upon the outworks; the central citadel of his system, the evolutionary hypothesis, still stands firm. A wider and wider circle of scientists and thinkers in general have accepted the system, but it has not yet been decided what will be the eventual conclusion of cultivated mankind. The philosophical system of Herbert Spencer claims to be the most solidly based of any now in existence, as the only strictly inductive system the world possesses. Modern philosophers may be divided into two classes on national lines of separation, the several German systems being all deductive, and attending far more to conclusions than to facts; the English, and after them the French, being essentially inductive, and considering facts as of primary, conclusions of secondary, importance. Of the several English and French systems, however, this is most particularly the case with that of Herbert Spencer. His idea of evolution was gradually worked out through diligent study and widespread comparison of the facts discovered by science, beginning with its application to the laws of society, and gradually extending, as his studies widened, till it embraced the whole universe. This gradual growth, through the study of scientific facts, is essentially different from the deductive method of reasoning out a universal principle to begin with and then seeking support for it in facts. In the explication of his system, however, Spencer has been forced to adopt the latter method, first applying his theory to the basic conditions and relations of the universe, and then seeking their support in recorded facts. The latter labor constitutes the bulk of his work, which seems to

many overloaded with illustrative particulars, every step of the gradually unfolding argument being supported by an extensive array of quoted illustrations, and the whole work founded on a broad basis of the phenomena ascertained and recorded by modern science.

That any speculative philosophical theory can be indubitably established in this or any other manner cannot be affirmed. There may be no chance for two opinions respecting the characters of a mineral body, but the primary cause of gravitation, of animal development, etc., will always be open to a diversity of opinion, and dozens of theories in regard to the same phenomenon may be honestly entertained and susceptible of some degree of corroborative evidence. Yet the fact remains that the theory which accords with the greatest number of observed phenomena, which offers the most satisfactory explanation of nature's mysteries, and which meets with the fewest discordant phenomena, has the soundest standing as a law of the universe. Spencer has earnestly labored to sustain his theory by illustrations drawn from every field of science, and marshalling accordances into a cumulative array of evidences; though not until all facts are known, and all shown to be in strict accordance with a proposed law of nature, can an irrefutable system of philosophy be established.

As a logician and a thinker of broad grasp and deep powers of analysis and synthesis, Herbert Spencer has had few equals in the history of mankind. He is generally conceded to have unusual mastery of method, breadth of view, and capacity of organizing ideas, and none of his positions are easy of overthrow, however strong in fact and argument be his opponents.

Spencer, as has already been stated, is in imperfect health. His health was so broken when he began his great work that few of his friends believed that he would be able to go on with it, and of recent years he has been virtually obliged to abandon it, though he may yet live to complete it. He is a bachelor, living in a quiet boarding-house in the West End of London, and so careful and systematic in all his habits, literary and otherwise, that he has been enabled to do far more work than would otherwise have been possible to him. He visited America in 1882 and delivered some lectures, though soon obliged to give up all exertion in consequence of ill-health. In London he is a regular frequenter of the Athenæum Club, and makes billiards, concerts, and theatrical entertainments his principal amusements, alternated with long country-rambles, of which he is very fond. He has persistently refused to join scientific societies or accept university honors, or to yield to anything which might distract him from the chosen work to which he has devoted his life and strength. (C. M.)

SPIDER, an arthropod animal of the family *Araneidea*, order *Arachnida*, this order embracing also the mites and scorpions. See Vol. II. p. 271 (p. 237 Am. Rep.). The *Arachnida* seem intermediate between the Crustaceans and Insects, differing from the latter in the close union of the head and thorax, the possession of simple eyes only, and the absence of antennæ and wings. There is no transformation, the young being born with the form and instincts of the adult. Maturity is reached after six moultings of the skin. The spiders possess four pairs of legs, an unsegmented and more or less spherical abdomen, and respire by means of both lungs and tracheæ. They are all carnivorous, and are provided with mandibles adapted to aid in taking their prey, the mandible ending in a powerful hook and being supplied with a poison-duct. The ocelli, or simple eyes, number 8, 6, or 2, in different species.

A peculiar and highly interesting characteristic of the spiders is their power of making silk, and the varied uses to which this substance is applied. Unlike the product of the silk-making insects, which is exuded from the under-lip, that of the spider comes from jointed spinnerets situated behind the anus, most spiders possessing 3 pairs of these appendages. They are conical papillæ, surrounded by stiff bristles and hairs, and dotted at the apex with horny tubes varying from 100 to 1000 in number. The silk is secreted as a viscid liquid, which dries and hardens immediately on contact with the air. The silken filaments are very strong and fine, one coming from each tube of the spinnerets, while each line of the spider-web is composed of hundreds or thousands of smaller ones. According to Leuwenhoek it would take 4,000,000 of the fine filaments to make the size of a human hair. The supply of silk seems sufficient to make 6 or 7 webs during the season.

The sexes of spiders are separate, the males and females living apart. The females are oftenest seen, and are the larger, often considerably so, while their carnivorous instinct leads them frequently to attack and devour the males, even in the reproductive season. Spiders ordinarily obtain nutriment by sucking the juices of their insect prey, but sometimes swallow the flesh. They can support long fasts, and spend the winter in a torpid state. They are very cleanly in habit, and spend much time in clearing their body and limbs of dust and dirt. They have much ingenuity and perseverance, and display considerable intelligence in adapting themselves to circumstances and in changing the form of the web to suit the locality.

Nine-tenths of all spiders are included in the following families, as named and described by Emerton. The *Mygalidæ* embrace the largest tropical species. They usually have very hairy and dark bodies, with only two pairs of spinnerets, one pair being very long, and turned up behind the abdomen. There are four air-sacs under the front of the abdomen, instead of two as in other spiders. The mandibles are very large, and work up and down instead of sideways. Most members of the family belong to the tropics, but there are some species in the southwestern United States. Some of the *Mygalæ* are very strong, *M. avicularia*, the bird-eating spider, being about 3 inches long, while its legs spread over 8 or 10 inches. It leaps upon and destroys humming-birds and other small birds.

The *Dysderidæ* form a small family, of which there are few North American species. They are usually found under stones, the legs being drawn up close to the body. They have 6 eyes, and 4 breathing-holes, one pair of which leads to branched tubes instead of to sacs. The *Drassidæ* are a large family whose members vary greatly in shape, color, and habits. They, like the above, make no webs, but usually live under stones, or in silken tubes on plants. They have small eyes arranged in two rows on the front of the head, and long spinnerets. The *Agelenidæ* are a tribe of long-legged web-building spiders, of a brown color, and with one pair of spinnerets longer than the others. They build flat webs with a funnel shaped tube on one side, which forms the den in which the spider lies in wait for its prey. The *Cinifloridæ* are similar to the above, but differ in the possession of a peculiar spinning organ. This, called the cribellum, lies in front of the spinnerets, and has much finer tubes. The threads from it are drawn out and tangled, and are attached to the plain threads of the web, serving to make it more adhesive.

The *Lycosidæ*, or running-spiders, form a numerous and interesting family. They live in open places, build no webs, and are very active in their movements, they having long legs, of which the

rear pair is the longest. The head is held high, giving an aspect of vigilance to the animal. The name of the family refers to their wolf-like habit of running down their prey. The *Altidæ*, or jumping spiders, have usually a short body and square head, with a peculiar arrangement of the eyes, there being two large ones in the middle which give them a look of special animation. Their legs are short, it being their habit to leap on their prey. The *Thomisidæ*, or crab-spiders, have bodies usually flat and widest in the rear, and somewhat resemble the crab in appearance. The front two pairs of legs are longer than the rear ones, and are bent in such a manner that the spider can readily move in a narrow crack. Some walk sideways, like the crabs. They build no webs.

The *Theridiidæ* form the largest family of the spiders. They are generally of small size, with large rounded abdomens and slender legs. They build large webs, whose shapes differ for different species, and rest, head downward, under these webs, holding on by their feet. The most interesting family of web-builders are the *Eperidæ*, the makers of the orb-like, geometrical webs which form attractive objects of spider-architecture. The species of this family are large in size, with short, round abdomens, flat heads, and eyes widely separated. The webs are made in lines radiating from a centre, and crossed by adhesive lines wound in a spiral or in concentric circles. Like the last-named family, the *Eperidæ* hang head downward in the web, or in other cases live in a hole near by, keeping in constant communication with the web by the aid of a connecting line.

The ordinary belief that spiders are aggressive and poisonous is based rather on prejudice than fact. If not disturbed, they will not bite, though all spiders will bite when cornered. There are few satisfactory instances on record of their biting man, and stories of injury from spider-bites are mostly erroneous. The great majority of spiders are undoubtedly harmless to man, the tarantula, and perhaps one or two other species, being the only ones that need be avoided. Fear and prejudice, rather than fact, have given the spider its bad reputation.

It is by their spinning habits that the spiders are specially distinguished from other animals, the silken line, which is principally employed by insects in making a cocoon, or a nest for their young, being applied by the spider to a considerable variety of purposes. The spinning instinct is so strong that it is manifested by the young as soon as they have left the egg, those of certain species dwelling together in a common web till they are strong enough to build for themselves. Spiders in confinement begin to spin at once, and do not seem comfortable till they can go everywhere within their bounds on the web. As they walk, they draw out a thread behind them, while the young of many species, and the adults of some small species, use the silken thread as a means of flight, emitting sufficient to support them in the air by its buoyancy. It is believed that when they wish to descend they draw in a portion of this flying thread.

The leaping spiders make another use of the thread. When springing from a vertical wall on passing insects, as they frequently do, they always remain attached to the wall by a thread, and are thus drawn back and saved from falling. The water-spider makes a small silken tent on plants beneath the surface. This opens downward, and is filled with air which its occupant carries down, a bubble at a time. Thus domiciled, it runs about on the water-plants, and catches the minute insects that live upon them. Its hairs keep the water from its skin. Some species that live on land-plants make flat tubes of silk, in which they lie in wait. Others

build tents near their webs as lurking places. The species which live under stones, or in other places of concealment, all line their residences with silk. The large and well-known webs are built by comparatively few species. Of these there are a great variety, from the regular orb-web to that of irregular threads with a tubular den, which is common in grassy fields, and to the dome-shaped web, whose shape is retained by threads which run in various directions. One species builds a double web, under the upper of which it lives. The purpose of the lower is not known. The orb-weavers are usually bright-colored, and hang in the web with no attempt at concealment, but some species cover a place in the web with rubbish, under which they lie hidden.

Among the most interesting of the spiders are those known as trap-door spiders. The habit of building underground can be traced through a considerable variety of stages. The running spiders, when ready to lay their eggs, seek or make a hole in the ground, which they line with silk for a nest. Others dwell habitually in such silk-lined excavations, and build round the mouth rings of sticks and stones held together by web. In the species known as turret-spiders the circular excavation is about an inch in diameter and two inches deep, above which is built an irregular pentagon of bits of grass, straw, weeds, etc., crossing at the corners and bound with silk, rising to a height of 2 or 2½ inches. The inner surface is silk-lined, and the inmate crouches at the summit of his tower, peering out for prey. On the sea-shore turrets of tiny pebbles are made, and the sand of the tunnel is held firm by its silken lining. The trap-door spider constructs a similar underground tunnel, the summit of which is closed by a hinged lid, whose surface is covered with moss and other materials to make it resemble the neighboring ground. Just inside this door is the inmate's lurking place, where it clasps the door and holds it down so firmly that it cannot be opened without tearing. The foraging period of this spider is at night, at which time the door is thrown open and it ventures to some distance from its fortress in search of prey. Some of the trap-door species have a second tube, opening into the first, the entrance being closed by a valve-like trap not distinguishable when shut from the remainder of the tube. In still other species this second tube ascends to the surface, and affords an avenue of escape in case enemies should break through the two trap-doors. Insect ingenuity could scarcely go further.

Another common use of the silk thread is in the making of cocoons for the young. These are small, round bags in which the eggs are laid. They are lined with the softest silk within, and often woven so closely as to be very hard and firm without. The spider pays great attention to its cocoon, which in some species is held by loose threads in the web, in others suspended by a stem. Some large species make a pear-shaped cocoon, which is attached to grass or bushes. Others build a hemispherical one against a flat surface. The running spiders carry the cocoon with them, attached to their spinnerets, and the young, when hatched, are carried for some time on the back of the mother.

Attempts have been made to use the silk of the spider as a material for fabrics, but with little success. The most recent experiments are those made by Prof. Wilder with a large southern species. He believes that an ounce of thread can be got from each spider during the season, this thread being from .007 to .004 inch thick, and much smoother and brighter in color than that of the silk-worm. Its fineness is such that several threads need to be twisted to obtain a size suitable for use. The difficulty in obtaining the silk, the labor in providing the spiders with food, and other impediments, make

the industry too expensive to promise satisfactory competition with insect silk.

Comparatively little is known about the senses of spiders. The general impression that they hear well, and even enjoy music, is not based on fully established facts. They are very sensitive to vibrations, and this probably has much to do with their apparent sense of hearing. The possession of a stridulating organ by some species, however, is an argument in favor of their hearing. They seem to be short of sight and with little power of appreciating form, their simple eyes being very imperfect organs of vision.

Spiders have many enemies, which attack both the eggs and the mature animals. Parasitic insect eggs are laid in the cocoons, and the larvæ, hatching first, prey on the young spiders. The mature spiders are eaten by savages in many parts of the world, and supply food to birds, reptiles, and insects. They are affected and frequently destroyed by parasitic mites, and some species are destroyed in considerable numbers by wasps, which paralyze them by a sting, and then store them in their egg-cells as food for their young when hatched. The spider, on the other hand, is very wary and alert in escaping his foes. Many of them have special lurking places and only venture out to take their prey, others conceal themselves in the web, some have the habit of shaking the web when in danger so violently that they cannot be seen, and many others when attacked at once fall from the web to the ground, and thus seek to escape peril. (C. M.)

SPOFFORD, AINSWORTH RAND, Librarian of Congress, was born at Gilmanton, N. H., Sept. 12, 1825. Failing health having prevented him from entering college, he removed to Cincinnati, and established himself as a bookseller and publisher. In 1859 he was engaged as associate editor by the *Cincinnati Daily Commercial*, and two years later he entered the Congressional Library, becoming librarian in 1864. Under his administration the national library has grown from 70,000 to upward of 600,000 volumes. The office of librarian has become an important one through the change in the copyright law effected in 1870. By this, all American copyrights are issued from his office, and copies of all copyright publications must be deposited in the library. Mr. Spofford has written much for the periodical press, and has published catalogues of the Library of Congress; *The American Almanac and Treasury of Facts* (annually since 1878); *Library of Choice Literature* (10 vols., 1881-88); *Library of Wit and Humor* (5 vols., 1884); and *Manual of Parliamentary Rules* (1884). In 1881 he received the degree of LL. D. from Amherst College. As a librarian he is known widely for his thorough knowledge of books.

(F. L. W.)

SPOILIATIONS, FRENCH. This term in American history, denotes the losses sustained by the owners of American ships confiscated by the French government during the war between France and England between the years 1778 and 1800. Under the Milan decrees of Napoleon, made to counteract the British Orders in Council, between 600 and 700 American ships and their cargoes were seized and sold. Jefferson, as U. S. secretary of state, in 1793 called on all merchants who had suffered or might thereafter suffer injuries, "contrary to the laws of nations and existing treaties," to forward the evidence of their claims to the department of state. In the negotiations for the settlement of these claims, which terminated in 1801, the French conceded that the claims were just, and repeatedly offered to pay the cash due. On the other hand, certain French citizens had claims against the United States, and the French nation itself had a valid claim for damages. The private French claims were slight and easily settled, but the claim of the

French nation was great. Under the treaty between the French and the struggling American nation, concluded in 1778, not only did the United States agree to fight for the French in America, but they agreed to allow the French ships of war to carry prizes into American ports and there condemn and sell them at all times. In return for these concessions the French king recognized the right of the new nation, and also gave such other valuable aid during the Revolutionary war as enabled the colonies to attain their independence. The obligation of the United States to stand by the terms of the treaty of 1778 was manifest. The damages done by English cruisers to French colonies, which American ships of war might have averted, constituted a valid claim against the nation. But more than all France valued her right under the treaty to bring her prizes into American ports. The American nation was extremely anxious to get rid of the obligations to permit her to do so. It was one of the triumphs of Jefferson's diplomacy which enabled this country to free itself from the entangling alliance made during the struggle for liberty. Taking the claims of American shipowners, which were then worth their face interest in gold, Jefferson offered them to the French on condition of a release in full for all obligations on our part, and the bargain was closed. The American government had taken private property and used it for the public good. Everyone acquiesced. Even the merchants who had lost their ships were pleased, because the American Constitution said, "Nor shall private property be taken for public use without just compensation." In 1802 the claims were first reported to the House of Representatives by Mr. Giles, in behalf of a select committee appointed for their investigation, and again, in 1807, by Mr. Marion of South Carolina. These two reports were a favorable statement of facts without recommendation, probably on account of the unfortunate condition of the finances at that time. In 1818 there was an adverse report by Mr. Roberts; in 1822, to the House, by Mr. Russell; in 1824, by Mr. Forsyth. In 1826, under the administration of John Quincy Adams, all of the evidence touching these claims, gathered from the documentary history and from the ample material accumulated in the archives of the department of state, was for the first time completely presented to Congress, and never since has there been an unfavorable report to either House. The objections to the payment of these claims found in the adverse reports referred to, in the "views of the minority" accompanying some of the favorable reports, in the veto messages of Polk and Pierce, in a speech of Silas Wright, made in the U. S. Senate in 1835, were as follows: 1. They are stale. 2. That the condition of the finances of the country will not admit of their payment. 3. That at the time they arose there was a state of war between the United States and France. 4. That they were embraced in the Louisiana convention. 5. That they were embraced in the convention of 1831 with France. 6. That Congress annulled the French treaties and thus effaced them. In 1886 Congress passed an enabling act allowing the claims to go before the Court of Claims. The claims were allowed, but Congress has so far failed to make an appropriation covering the several amounts. The legislatures of the 13 original States have all at various times passed resolutions directing their senators and asking their representatives to take favorable action in behalf of these claimants. It is estimated that, if interest be reckoned on the claims at 6 per cent., the aggregate would now be about \$80,000,000, as they will have increased to 6 times the original amount. A few of the undivided claims are as large as \$50,000, the average of them being about \$4300. Most of them have the necessary evidence on file. A very elaborate history of the claims was made by the House

committee on foreign affairs in January, 1884 (*Report No. 109*). (P. O. M.)

SPORTS, ATHLETIC. This article is confined to the popular American athletic sports.

BASE-BALL is the "national game" of the United States. Two sources are claimed for it: (1) An old English game called "rounders;" (2) a game familiar in parts of the United States, fifty and more years ago, known as "town ball." The weight of evidence seems to favor "town ball," though that may have been but a variation of "rounders." "Town ball" was systematized by the Olympic Club of Philadelphia, organized in 1833. The prosperity of this organization attracted enterprising ball-players and led to the formation of the first base-ball clubs, two or three of which came into existence in New York in 1845. The Knickerbocker Club was the chief promoter of this development. It adopted playing rules, Sept. 23, 1845, and started the game under auspicious circumstances. In May, 1857, the National Association of Base-ball Players, composed entirely of New York clubs, drafted and adopted a new code of playing rules. In 1860 the Excelsior Club of Brooklyn, by its exhibitions in tours through the cities of Western New York, Pennsylvania, and Maryland, gave an impetus to the spreading popularity of the game. What the Knickerbocker Club did in the earlier period of the history of the game in establishing base-ball on a permanent basis, the Excelsior Club followed up by their successful efforts to extend its popularity. These tours resulted in the increase of the National Association from twenty-five clubs in 1859 to eighty in 1861. Meanwhile amateur clubs outside of the Association were organizing all over the country, and the game was becoming familiar to every American boy. Not only did boys take to the game, but young and middle-aged men grew fond of it. The old National Association had not been flourishing ten years before professionalism began to find a foothold in the institution, and in 1869 and 1870 this element became a ruling power in the Association. A division followed, which resulted in the organization of two National Associations. The new bodies were the National Amateur Association, organized in 1871, wholly of amateur clubs; and the National Association of Professional Base-ball Players, organized the same year, wholly of professional clubs, a distinction which has ever since been preserved. From this time professional clubs multiplied rapidly, and soon the desire for closer organization sprang up, and professional Leagues, with schedules of games to be played for various championships, were formed by clubs representing different cities. These operations did not interfere with the progress of amateur clubs, which also multiplied, and had their sectional leagues, schedules of games, and attractive aims. The only check in the wonderful prosperity of the sport occurred at this time through sundry evils connected with pool-selling and the "cracked" element in the clubs. But these flagrant evils were opportunely and effectually destroyed by the stringent laws of the National League, established in 1876, and the American Association, a new body of professional clubs, established in 1881. The old National Association had passed away and these two new bodies had taken its place. For some time there was strife between them as to which should have chief authority in the base-ball world; each set up rules and laws of its own, and the bitter rivalry threatened the destruction of the honesty and popularity of the game. But the differences were amicably arbitrated in 1882, when the National League, American Association, and the Northwestern League entered into the "Tripartite Agreement," which in 1883 was developed into the "National Agreement." The parties to this

document, which has become the fundamental law of base-ball affairs, are now (1889) the National League, composed of clubs representing the cities of Philadelphia, New York, Boston, Chicago, Washington, Pittsburg, Detroit, and Indianapolis; and the American Association, consisting of clubs representing the cities of Philadelphia, Baltimore, Brooklyn, Cincinnati, Cleveland, Louisville, Kansas City, and St. Louis. Other prominent associations are the International Association, formed of clubs in Canada and New York State; the Central League, formed of clubs in New Jersey and adjacent States; and the Western Association, formed of clubs in States on the Mississippi; and the California Association. The laws of the game and rules governing its play, as framed under this agreement, are adopted by every base-ball organization in the United States. The rules may be changed every year to meet the exigencies of the times and to keep pace with the improving skill of the players.

The number of clubs, professional and amateur, in the United States, would run far into the thousands, every city containing from one to a hundred of them, in the supply of which over 12,000 balls are made daily. The professional clubs have well-kept grounds, fitted with every convenience to make the game attractive. The Philadelphia Club expended \$100,000 on its grounds in improvements alone, the seating capacity of the grand pavilion being over 10,000 people. Other grounds seat as many as 15,000, and there occur times when 18,000 are in the grounds and thousands on the outside unable to gain entrance. Base-ball playing is now done on scientific principles, and adept players, with reputations, receive salaries of from \$2000 to \$4000 for a season of about six months. The players are held to the different clubs by approved contracts. As the success of a club depends largely upon the skill of its players, there is considerable competition every year in securing brilliant men; as high as \$20,000 is said to have been paid for the transfer of a first-class pitcher from one club to another. Considerable capital is invested in the sport, and the dividends are generally large.

Base-ball has not made much headway in other countries. Unsuccessful efforts were made to intro-

duce it in England, but there is an earnest endeavor to popularize it in Australia.

The following is a diagram of the ground, as it is required under the existing regulations.

The grounds are always diamond-shaped. At each corner is a square, called a "base." The bases, numbered first, second, and third, are marked by canvas bags, while home base is made of rubber. Home base is the starting-point in the game, and is directly in front of the catcher; first base is diagonally to his right. Lines drawn from the outer corner of the home base through the centre of the first and third bases, to the boundaries of the ground, are called "foul lines." The part of the field inside the diamond is called the infield; that outside of it, but inside the "foul lines," is called the "outfield."

In a game nine players are required on each side; these are a catcher, pitcher, first, second, and third basemen, short stop, left, centre, and right fielder. Each club has a captain, who is always one of the nine players. Each has a tenth man as a substitute when a regular player is recalled or disabled. The positions of these players are indicated in the diagram; their duties are prescribed by rules. As to their abilities, each must be a good fielder and a good batsman, and if he is also a good base runner so much the better. He must be a sure catcher and swift, accurate thrower. The most responsible position is that of pitcher. His skill and tact generally decide the game.

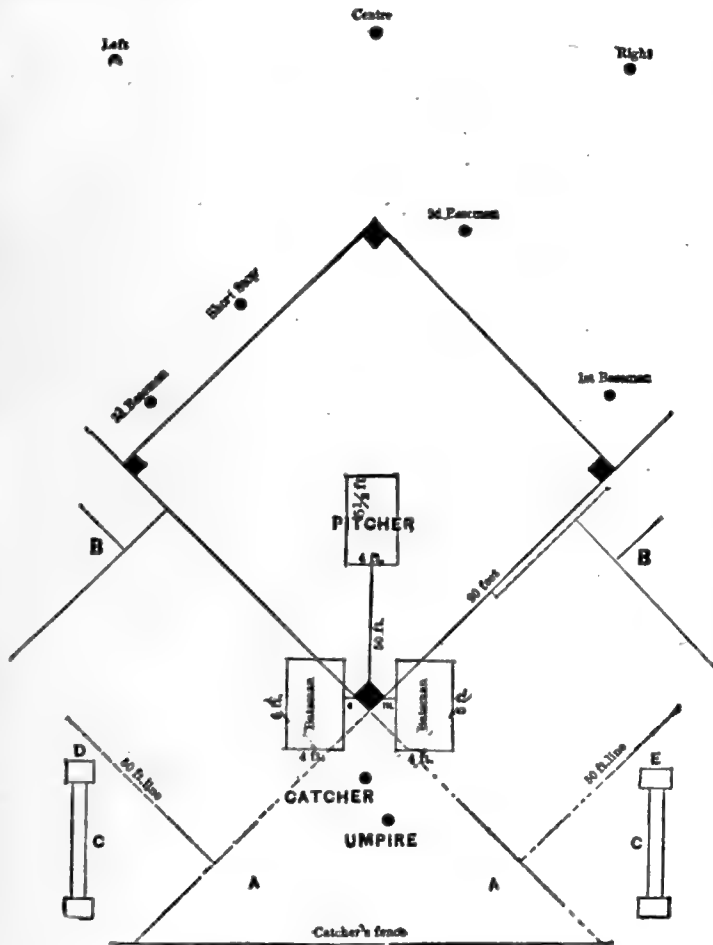

FIG. 1.—Base-ball ground.

A, A, Reserved for Umpire, Batsman, and Catcher; B, B, Reserved for Captain and Assistant; C, C, Players' Benches; D, E, Bat Racks.

Next to him is the catcher; and next, the short stop. The umpire is a judge regularly appointed to decide all points of dispute that may arise during the game. He also superintends the play, signifies when the game is to begin, passes judgment on all balls pitched by the pitcher, and decides whether the players are "out" or not. In short, he is master of the field from the commencement to the termination of the game, and must compel the players to observe the provisions of all the "playing rules." He generally stands behind the catcher, that he may see and judge the balls thrown by the pitcher and watch the players and plays.

The materials for play are a ball and a bat, no more than one ball and no more than one bat being used at a time. But if a ball be lost or ripped, or a

bat be broken, a new one can take its place. Each batsman generally has a bat to suit his own taste and strength. The ball is spherical and elastic enough to spring when hard hit, but not so elastic as pure rubber. It must weigh between 5 and 5½ ounces avoirdupois, and measure between 9 and 9½ inches in circumference. The bat is a round, tapering club, though a portion of the surface may be flat on one side; it must not exceed 2½ inches in diameter in the thickest part and must not exceed 42 inches in length. The bases are canvas bags stuffed with saw-dust or excelsior; the home base being made of rubber, that it may have a flat surface and avoid injury to runners. The catcher uses a wire mask, inflated rubber chest-protector, and padded gloves; the pitcher wears a brass toe-plate; the first baseman also wears padded gloves. The players are uniformed, each club wearing regulation hats, suits, belts, and shoes.

A Match-game—With the above facts in mind, a still clearer knowledge of base-ball can be obtained by going through a game. Therefore let us play one or two "innings," and introduce the "points" as they occur. We will suppose the game to be between the Philadelphia and Chicago Clubs. The two captains having decided by toss which shall go out in the field and which shall stay in to do the batting, the umpire "calls" the game to begin. The Philadelphia players have the "outs" and take their places in the field; the Chicago Club have the "ins." When three of their players have been "put out," their whole side will be "out," and the Philadelphia club will take its turn at the bat. The game usually consists of nine of these double innings. All being in readiness, the umpire calls "game," tosses a new ball to the pitcher, and prepares to judge the throwing. The first batsman of the Chicago Club steps into the quadrangle, beside home base, and gets ready to hit the ball. The Philadelphians wish now to prevent the batsman from reaching first base. The pitcher wants to throw the ball in such a manner as to deceive the batsman and make him "strike" out. The batsman's aim is to avoid this by hitting the ball so that he may run and reach first base before the ball can be thrown there. The pitcher takes careful aim and sends the ball whirling toward the catcher. Every ball must pass over the home base between the knees and shoulders of the batsman. Every time it fails to do this, the umpire calls "ball," and every time the ball passes as required, he calls "strike," whether the batsman aims at it or not. Four of these "balls" entitle the batsman to run to first base, while three of these "strikes" put the batsman "out;" i.e., force him to give place to the next batsman, so that, generally, the pitcher has never to pitch more than seven balls to decide whether a batsman goes out or not. The game being now in motion, let us suppose that the batsman has tried to hit the ball with his bat, but has failed. This failure may be owing to the speed of the ball or the curve it takes, and the batsman's misjudgment. Every such attempt and failure to touch the ball is called also a "strike," and three of these will put him out. In other words, a batsman can be put out on "strikes" in either of two ways: on strikes called by the umpire or on strikes made by himself. At length he knocks the ball into the field along the ground in such a way that the fielders fail to stop it before he reaches first base. This is called a "base hit." He has now become a "base runner," and his object is to reach second base, then third base, and then "home." He can do this in either of two ways: run swiftly to second base while the ball is passing from pitcher to catcher, or wait till the next batsman hits the ball, and sends him to second base. If he does the former he is said to have "stolen" second base; if the latter, he has been

"forced" or helped to second base. Bataman No. 2 knocks the ball "fair" enough, because it goes in front of the "foul lines," but it flies up into the air, and is caught in the air by centre fielder, and held. This is called a "fly" ball, and batsman No. 2 is said to be "out on a fly." No. 1 is still on first base, not being allowed to run on a caught "fly," and No. 3 steps up to bat. He knocks the ball and it rolls slowly toward first baseman, who picks it up and touches his foot to the bag before No. 3 can reach there, but not quick enough to prevent No. 1 from running to second base. This puts No. 3 out. There are now two men out, Nos. 2 and 3, and only one more needs to be put out to prevent No. 1 from reaching "home" and scoring a run. No. 4 hits the ball so hard as to send it flying over the head of the left fielder, and before it can be stopped and thrown in toward the pitcher No. 1 has touched third base and the home base, and scored a run; while No. 4 has reached second base, having made a "two-base hit," because he reached second base before the ball did. No. 5 comes to bat, and while waiting, the pitcher, trying to catch No. 4 napping, makes a feint to pitch the ball but does not do so. The umpire detects him, and calls it a "balk," which permits No. 5 to take first base, just as if he had hit the ball, this being the penalty for "balking." There are now two men on bases and No. 6 comes to bat, but while he is waiting to aim at the ball No. 4 tries to "steal" third base; but the pitcher, ever-watchful, detects him, hurls the ball to third baseman, who catches it and touches No. 4 before he can reach the base. This puts him out, and (since three have now been "put out") closes the Philadelphians' part of the "inning." The Chicagos now go into the field, and the Philadelphians come in to bat. Batsman No. 1 steps up to bat. He hits the ball fiercely to short stop, who picks it up and throws it swiftly toward first baseman, but it is too high and goes over his head. Before it can be recovered No. 1 has reached the base. He has gained so much on an "error"—made by the short stop. No. 2 waits in vain for a "good" ball. The pitcher is excited by the short stop's mistake, and throws the ball so wildly that the umpire calls "ball" after "ball" until four are counted, and No. 2 goes to first base. This forces No. 1 to second base. Nobody is out yet, two men are on bases, and No. 3 is ready to bat. The pitcher is still unstrung, and pitches so wildly that the ball hits No. 3 in the side. The umpire tells No. 3 to take his base, this being the penalty for hitting a batsman with the ball. No. 3 forces No. 2 to second base, and No. 2 forces No. 1 to third base. The bases are now said to be "full" and no one out. The chances for "runs" are excellent. No. 4 takes up the bat and knocks the ball to short stop. Every man is forced to run. It is a critical stage. Short stop picks up the ball, touches No. 2 like a flash, and then throws the ball to the catcher, who receives it before No. 1 can reach home. Two men are thus put "out"—No. 2 and No. 1—and a "double play" is made. There are now two out, and two men on base: No. 3 on second and No. 4 on first base. The Philadelphians are anxious for a "run," and No. 5 hits the ball so hard that it goes far beyond centre fielder, and before it can be recovered No. 5 has made the whole circuit and reached "home," making a "home run" and sending in Nos. 3 and 4, each with "runs" to his credit. No. 6 hits the ball, but it goes up into the air outside of the "foul lines." The catcher is nimble and catches it before it touches the ground, and No. 6 is said to be out on a "foul fly." Three men are out, and the other part of the "inning" is finished. Two such parts make up an "inning" and nine "innings" constitute a game. The "score" for this first inning is 3 runs to 1 in favor of the Philadelphians; and the Chicagos come

in to bat again. And so the game goes on, alternately, until nine innings are finished, the club having the most runs winning. If the score be even or "tie," more innings have to be played until either side exceeds the other. Games usually begin at 4 p. m. and last two hours. If darkness gathers before the game is done, the umpire can call the game to stop, and the club which is then ahead wins.

The season for base-ball is from April 15 to October 15, the summer months being the most favorable time.

(H. R. R.)

Dr. Leuf's *Hygiene for Base Ball Players* (A. J. Reach & Co., Phila.) gives the following explanation and illustrations of "curve-pitching," as now practised. Its principles have been thoroughly investigated, both as regards the varieties of curve and the muscular effort required to effect them. The object of

Always aim over the plate and the ball will be seen to curve in, the amount of the curve depending upon the rapidity of the twist imparted to the ball by the fingers. The greater the full-length swing of the arm, the greater is the speed and more sudden the curve of the ball. Sudden sharp curves are called "shoots," and the in-shoot is the most marked because it is easiest to give it the most rapid twist and the swiftest momentum. The twist of the in-curve ball is forward and from left to right, and any kind of delivery that will give it this gyration with sufficient rapidity will cause the ball to curve in.

The out-curve, so called because it turns out from the batsman, is generally produced by rolling the ball off the thumb side of the index-finger with the palm turned up and the little-finger edge of the hand facing the opposite shoulder (Fig. 3). As in

FIG. 2.—In-curve.

the curve pitching is to outwit the batsman while the pitcher gains a point for the benefit of his own side. There are four curves used: The in-curve, the out-curve, the down-curve or drop-ball, and the up-curve or rising ball, which are here explained.

The in-curve, so called because it turns in toward the batsman, is produced by rolling the ball off the tips of the fingers with the palm of the hand facing directly forward (Fig. 2). The ball must be grasped with sufficient firmness to prevent its premature slipping out of the hand. The arm is drawn back, and with a full-length swing brought forward, usually on a level with the shoulder. When about opposite the shoulder, the elbow is bent in toward and across the chest, at the same time sharply bending the wrist and making a sudden jerky finger pressure upon the ball to give it the necessary twist.

FIG. 3.—Out-curve.

every kind of pitching, the arm is first drawn well back so as to give it plenty of swing in coming forward in delivery. The elbow is slightly bent and, as the arm comes forward and just before letting go the ball, there is a simultaneous side-bending of the wrist on the little-finger side toward the opposite shoulder, and a slightly jerky movement of the elbow backward and away from the body. These complex movements send the ball out of the hand with a sudden jerk from the thumb side of the index-finger, with the hand upturned, and give the ball the requisite twist to make a good curve and also insure adequate speed. The twist of the out-curve ball is forward and from right to left.

The down-curve or drop-ball, so called because it descends sooner than if it had been thrown in the ordinary manner, is rolled off the thumb side of the

index-finger as in the out-curve, with the difference that the palm, which is now brought over the shoulder, is turned directly upward, with the little-finger side facing the breast (Fig. 4). The arm is first

thumb side of the index under the hand. This is a necessary movement—to impart the proper twist, and at first is found difficult to execute. The ball leaves the hand with a remarkably sudden jerk, and on that

FIG. 4.—Down-curve.

swung back behind the head, from which position it is brought forward on about a level with the top of the head. In this the mode of drop-ball delivery the elbow is of course necessarily bent. Immediately after passing over the shoulder, the arm is as suddenly and as forcibly as possible pulled down, the palm is turned up, and the hand bent in toward the chest on the little-finger side, and the ball permitted to roll off the thumb side of the index-finger. The sudden, shoulder motion must be mainly depended upon for speed, while the wrist motion determines the rapidity of the twist, and hence the extent and suddenness of the curve.

The up-curve, or rising ball, so called because it has a peculiar ascending motion, and falls to the ground farther away than if it had been thrown in the ordinary manner, is the most difficult to master, but always the easiest curve to make when once learned (Fig. 5). Here the ball is also rolled off the thumb side of the index-finger, but in a manner that at first is extremely awkward, and, in fact, seems almost impossible. The body is bent forward, and the arm drawn back and well up so as to get a good start for the forward swing. As it is brought down at full length it comes forward at about the level of the knee, and just here the palm is turned as far upward and backward as it can be twisted, with the little finger side directed upward toward the face of the pitcher and also slightly bent back, when the ball is permitted to roll off the

FIG. 5.—Up-curve.

account gets great speed and a very good twist and resulting curve.

(A. H. P. L.)

FOOT-BALL is not so popular in the United States as base-ball, and has no professional clubs. Its principal favor is with students in academies and colleges. There are amateur associations, and several intercollegiate leagues, and by these the game has been made somewhat scientific. The principal football organization is the American Intercollegiate Association, comprised of "elevens" from Harvard, Yale, Princeton, Wesleyan, and the University of Pennsylvania. This body yearly arranges a schedule of games which are played for the championship of the United States. The contests between these "elevens" create wide interest and are played before crowds of 5000 to 15,000 people, who pay liberally for the privilege. Yale has won the championship pennant in 1876, 1881, 1882, 1883, and 1888. Foot-ball, as played in the United States, resembles the Rugby game more than the Association or Harrow game of England. Under the rules of the American Intercollegiate Association the game is as follows:

The field is rectangular, 330 by 160 feet. The rectangle is outlined by broad whitewash lines, as in tennis. At each end are the "goal lines." Inside of these and the side lines the game must be played. Parallel with the goal lines and running across the field at a distance of 75 feet from each goal are lines called the "25-yard-line limit of kick-out." In the

middle of each goal line stands the *goal*—two upright posts, exceeding 20 feet high, and placed 18½ feet apart, with a cross-bar 10 feet from the ground. Every ball, to count in the score, must cross the goal line. The value of each point in scoring is: Goal from "touch down," 6; goal from "field kick," 5; "touch down" failing kick, 4; "safety," by opponents, 2.

The ball is of oval shape, inflatable, made of India-rubber, and cased in leather. A foot-ball team consists of seven "rushers," known as centre rusher, his right and left guards, and two end rushers; one quarter-back, two half-backs, and a full-back. The captain is one of the eleven, and directs the movements of his team. The main office of the rushers is to keep their opponents away from the ball. The centre rusher puts the ball in play, and should be a man of weight and muscle. The quarter-back looks after the disposition of the ball. The half-backs must be wiry, swift, and deep-chested. The full-back is the emergency man, and must be a good kick and a sure "tackler." There is an umpire and a referee: the umpire is judge for the players, and his decisions are final regarding "fouls," i.e., violations of rules and unfair tactics; the referee is judge for the ball, and his decision is final on all points not covered by the umpire. The time of game is usually 1½ hour, each side playing 45 minutes from each goal, with 10 minutes intermission between the two halves. The game is decided by the score of even halves.

Foot-ball can be best illustrated by going through and explaining the steps in an actual game. Let us describe a contest between the Yale and Harvard "elevens."

The two captains toss up for choice of goal or "kick off." (A "kick off" is a "place kick" from the centre of the field of play and cannot secure a goal, a "place kick" being made by kicking the ball after it has been placed on the ground.) Yale wins the toss, and the rival teams walk into the centre of the field. Here there are three lines, running parallel with the goal lines, five yards apart. The centre line is for the ball; the other two are for the rival "rush lines," made up of the seven "rushers." The rushers face each other, spreading out, with their faces toward their opponents' goal. Behind the centre rusher stands the quarter-back. Five yards behind him, diagonally to his right and left, stand the two half-backs, and ten or more yards behind them, centrally, stands the full-back. Between the two lines of rushers, five yards directly in front of the centre rusher, is placed the ball.

The Game.—All in readiness, the referee signals to begin. The ball can be put in play only by the centre rusher in one of two ways, as directed by the captain: viz., either kick it strongly toward Harvard's goal, a proper "kick off;" or lift it with his toe, catch it as it rises, and pass it behind him to his nearest man, a feint to "kick off." The latter is the commonest and safest mode of opening. Yale's captain having signalled the centre rusher to feint, he passes the ball quickly to a chosen man, generally a half-back. Yale's aim is to get the ball over Harvard's goal line, while Harvard's object is to prevent such success. Accordingly the Yale man, with the ball, darts for the coveted goal, while his colleagues strive to block and keep away from him their opponents. He has hardly gone ten yards before a burly Harvard man, bursting past every obstacle, seizes him round the waist and drags him to the ground. This is called a "tackle," and the man with the ball cries "down," and is released. The scattered teams reform, or "line up," on the spot, facing each other as before. As the Yale man clung to the ball, it goes again to his centre rusher. It can now be put in play either by a "kick off," by the centre rusher, or

by being "snapped back," when it must touch at least three persons. The first way is usually impracticable, so the centre rusher, at a signal from the quarter-back, snaps the ball backward with his foot toward the latter, who seizes it instantly and throws it to a signalled half-back, who proceeds to dart between the enemy or out around them, while after him rush the Harvards, harassed and impeded by the Yale rushers. The man with the ball is surrounded, but before he can be "held" he passes the ball back to one of his men, who continues the dash, and immediately becomes the object of attack. In attempting to run round the enemy, he is forced beyond the limit line at the side. He must now stop and come back to the point where he passed "outside." The men "line up" as before, and now the ball must be put in play by the end rusher nearest the side line. He can do it in either of the ways allowed the centre rusher, but he chooses to snap it back, and the quarter-back passes it to the half-back, who tries to force his way through the battling crowd. (The moment a "snap back" is made, the Harvard rushers spring in and strive to break through the Yale "rush line" and capture the ball. Here the heaviest fighting occurs. The rules forbid the use of fists in fighting through the crowd, under penalty of disqualification. But the man with the ball can use his elbows, shoulders, or open palm to throw off assailants. The ball is always carried tightly under the arm opposite the enemy.) The half-back makes an attempt to dive between the men, but is caught suddenly and thrown and "held," i.e., intercepted—he is said to be "down." If in four of these "downs" the side with the ball does not gain at least five yards, the ball passes over to the other side. The possession of the ball is a decided advantage. The Yales have now three "downs," and must gain two yards to keep the ball. The goal with the chance of scoring is still 50 feet away. They "line up" quickly and the ball is snapped back. The quarter-back throws it to the half-back, who dashes gallantly through the crowd, gains clear ground, and makes for the goal, with the enemy at his heels. But he is too fleet for them, and, dodging the full-back, he crosses the goal line and touches the ball to the ground between the goal posts. This is called a "touch down," and counts 4 points. When a "touch down" is made the ball is brought back into the field, to a point on the "25-yard-line limit of kick-out" opposite the place where it touched the ground, and is held very close to the ground (but never touching it). The man thus holding the ball lies on his side and tries to drop it just in time for some one of his team (the most accurate kicker) to kick it through Harvard's goal posts and over the cross-bar. If he succeeds it is called a "goal from touch down," and counts 6 points. If he fail, Yale is credited with merely a "touch down." He succeeds, and so increases the score by 6 points. The ball is now placed in the centre of the field, as at first, and the elevens resume the positions they occupied at the beginning of the game, with the difference that Harvard has the ball. The game opens with a proper "kick off," and both sides sweep after the ball. It falls near the Yale goal line, and before Yale's full-back can return it, i.e., kick or carry it back, the Harvards pounce on him and have it "down." If, during the rush that is about to take place, the ball be forced back across Yale's goal line, or so near to it as to run the risk of a "touch down," Yale is permitted the choice of a fight or a concession. If the latter, they carry the ball over their own goal line and themselves make a "touch down," which is called a "safety" and counts 2 for Harvard. This is always a bitter resource. But if they decide to fight, the ball is put in play regularly and thrown to the full-back, who kicks it

high over all heads toward the Harvard goal. If the ball chances to go over the side bounds of the field both sides make a rush for it, and the side capturing it out of bounds bears it back just within the limits. If it strikes inside the field, the side catching it puts it in play. Harvard gets the ball, and they put it in motion, and their half-back breaks through all restraint and makes a "touch down." But as he did not get near enough the goal posts to make a "drop kick," his play is to "punt out" the ball (made by a player of the side which has made a "touch down" in the opponents' goal to another of his own side for a fair catch). His object is to punt so that the ball will be caught in front of the goal posts. Accordingly, Yale "line up" along their goal line; while Harvard, excepting the punter, "line up" 15 yards away, facing Yale. The punter takes his position among the Yale men, who must be 10 feet away from him on either side, and makes the "punt" by letting the ball fall from his hands and kicking it before it touches the ground. If a "fair catch" be made the ball is passed to a Harvard man, who holds it for a "drop kick" as before. But if the ball be missed, the moment it touches the ground it is in play again, and can be rushed by either side. The Harvard man misses the ball, intentionally or otherwise, but it is saved by one of his side, who grabs it, and the men "line up" again. (This "lining up" takes place every time the ball is about to be put in play.) The centre rusher snaps it back and the quarter-back throws it to the full-back, who "drop kicks" it unerringly through the Yale goal posts, making a "goal from field kick," which counts 5. The referee now calls "Time," and the first half is played. An intermission of ten minutes takes place, the score standing: Harvard, 9; Yale, 6. And so the game continues until the time is ended. All time lost by accidents or allowable delays is added to the regulation time, that the full limit may be occupied. In games between such teams as Harvard, Princeton, and Yale more than 15 points are seldom made by either side, a few points often deciding the game. But between these and inferior teams the score mounts even into the hundreds, Harvard defeating Exeter in 1886 by a score of 158 points to 0, the greatest on record. (H. R. R.)

JUMPING. In this sport the records are confined, for the most part, to amateur athletic associations. Among amateurs a fair record for the running broad jump is 17 feet 9 inches; and for the running high jump about 5 feet. Only a few years ago a standing jump of 5 feet 7 inches was considered marvellous, and but few American athletes could attain even that. Now there are several men in almost every large city who are able to accomplish it. There are many ways of approaching the bar practised by good athletes, but those who lead in this sport run toward it directly at right angles. When the bar is reached the body should be crouched as low as possible, as only by that means are all the muscles of the body brought into play. The leverage of the back is also important in assisting the jumper, and by constant practice the cartilages may be brought to a high state of elasticity. The method practised is to approach the bar with three unequal long bounds and two short ones, after which the crouching position is assumed. When making the final spring the jumper twists the right foot violently outward, after which both arms and legs are jerked suddenly upward to give additional impetus to the jump. The knees are brought into contact with the chest, thereby causing the body to occupy the smallest possible space when crossing the bar. The sudden twisting of the right foot outward imparts a similar motion to the body, thereby causing it to turn half-way round from left to right. When the body is near the top of the bar the right arm is

jerked toward the shoulder, and a similar motion with the left should follow. At the instant the arms are jerked the legs should be shot out from their doubled-up position, thus carrying the body still farther upward. The highest record of this sort was made by E. Byrd Page, who cleared 6 feet 4 inches, in Philadelphia, Oct. 7, 1887.

ROWING is a pastime which has closely followed the practice in England; but it differs from it, more especially with regard to the stroke. The stroke usually adopted in England, known as the "book-stroke," makes the rower reach forward as far as he can, and requires him to pull it clear through until his body is well past a perpendicular. At first scarcely any of the American oarsmen adopted this stroke; and yet they differed from each other as much as they did from the English stroke. The champion scullers, the professionals, and amateurs appear to vary as much as they possibly can in their ideas of what a correct stroke should be. It is described by Edward Hanlan, of Canada, long the champion of the world, as follows: "Instead of spreading my knees apart, as most rowers do when reaching forward, I sit in a natural position with my legs and arms directly in line as they stretch out before me. In coming back the knees close somewhat, but not entirely, the elbows come close to my sides, and the hands lap over about 6 inches. This wide spreading of the knees and stretching forward to the last inch of reach puts those who adopt it into a cramped position when their oars catch the water, thereby wasting strength and purchase. Open-handed oars I never use. For my great point is to utilize my every ounce of strength, and open-handed oars fritter away a man's strength by spreading his arms too wide when he takes the water. Being convinced that more speed is got out of the rowlock than forward of it, I pull an easy stroke until my body is straight in the boat, and then shove through steadily with all my strength, but so balancing the stroke as not to jerk the boat at the finish. I don't begin to slide until my oars have taken a good hold on the water, for I can only get all my weight on a stroke by having my legs and arms act simultaneously—that is to say, by bringing all my rowing muscles into play at the same time. Force is lost by a premature using of the slide. In turning, after getting just past the flag, I drop my left oar almost straight down into the water, with elbow close to side, put my whole weight on it, leaning slightly to the left, so that both ends of the boat are raised above the water and she can pivot on her bilge, and then pull her around with steady strokes of the right oar. Every inch tells in the long run, and it is by studying such little points as these that I obtained and keep my place as champion oarsman of the world." In the American colleges a variety of strokes was used until 1872, when the leading colleges began to adopt the English stroke. The results have shown that it has won more races than the hap-hazard strokes that have been adopted by the different crews from year to year. In 1883 the Yale College oarsmen adopted a very fast stroke, but they suffered defeat at the hands of the Harvards, who had adopted the long sweeping stroke of the English. The Harvards had adopted this stroke by degrees for ten years previously; and even the Yale men had won with the same stroke in 1876. The victory of the long stroke in 1883 was the more significant because the Yale men were giants in comparison with the Harvard men, and they kept up their stroke of 42 to 45 a minute to the very end without apparent fatigue. The inference was that the longer stroke was the best.

Among the professional rowers of America the Ward brothers, of Cornwall, N. Y., appear to have been the pioneers. Later, the championship of the

world was secured by Hanlan; and, in 1885, by William Beach, of Australia. The championship of America was won by O'Connor, of Toronto, in December, 1888. Among amateurs the leader for many years was Charles E. Courtney, of Union Springs, N. Y., who afterward became a professional and made the extraordinary time of 3 miles in 19 minutes and 27 seconds. In 1885 a great race was rowed at Albany between Courtney and Conley, on one side, and Hosmer and Gaudaur, for the double-scutt championship of the world. The race was won by Courtney and Conley.

Rowing in the United States has been more rapidly developed through the races between the several universities and colleges than through any other source. In fact, the history of these races may be said to have marked nearly all of the history of its advancement. In 1852 Harvard and Yale rowed their first race of 2 miles on lake Winnepiseogee, in New Hampshire. Harvard was represented by the Oneida, an 8-oared boat, 38 feet long; and Yale, by the Halcyon, also an 8-oared barge. Yale won by 2 lengths, the time being about 10 minutes. In 1855 Harvard put forward an 8-oared and a 4-oared boat; and Yale, two 6-oared boats. The former won. In 1859 Harvard had a shell and a lapstreak, Yale a shell, and Brown a lapstreak. Harvard was the victor. In 1859 Yale beat by 2 seconds; and in 1860 Harvard beat by 12 seconds. Down to this point the races were so irregular, as to the classes of boats entered, that no fair test could be made. In 1858 a movement was made toward an intercollegiate regatta. Harvard, Yale, Brown, and Trinity responded; but nothing was done until 1860, with the result above noted. The civil war postponed further efforts until 1864, since which time the record of the university races is as follows—the course being 4 miles.

Year.	Winner.	Time.		Won by.
		Minutes.	Seconds.	
1864.	Yale.....	19.01	42½	
1865.	Yale.....	17.42½	56½	
1866.	Harvard.....	18.43	27	
1867.	Harvard.....	18.13	72½	
1868.	Harvard.....	17.48½	50	
1869.	Harvard.....	18.02	9	
1870.	Harvard.....	20.30	Foul.	
1871.	Agricultural (three colleges).....	16.46½	37	
1872.	Amherst (six colleges).....	16.33	24	
1873.	Yale (eleven colleges).....	16.50	10	
1874.	Columbia (nine colleges).....	16.42	8	
1875.	Cornell (thirteen colleges).....	16.53½	11	
1876.	Yale.....	23.02	20	
1876.	Cornell (six colleges).....	17.01½	4	
1877.	Harvard.....	21.36	7	
1878.	Harvard.....	26.44	45	
1879.	Harvard.....	23.15	03	
1880.	Yale.....	24.27	43

1883.	Harvard.....	20.40	73	
1884.	Yale.....	20.31	15	
1885.	Harvard.....	25.15½	74½	
1886.	Yale.....	20.41½	10	
1887.	Yale.....	22.56	14½	
1888.	Yale.....	20.10	74	

In 1883 Cornell beat Pennsylvania, Princeton, and Wesleyan on Lake George; and in 1884 Pennsylvania beat Princeton, Cornell, Columbia, and Bowdoin. For a time Harvard and Yale had everything their own way. In 1871 Harvard, Amherst, Brown, and Bowdoin organized the "Rowing Association of American Colleges," for the purpose of using the course at Springfield, Mass. In 1872 Harvard was defeated by Amherst, and Yale was the last to reach the goal. This result encouraged boating among the smaller colleges, so that in 1873 eleven crews entered. Disputes having arisen in regard to the line of finish, there was a disagreement upon the results between Harvard and Yale for several years which helped

other colleges to win the intercollegiate races. Harvard and Yale, however, met again in 1876, and the contest between the two leaders has been continued to the present day.

The original Oneida, of the Harvards, was a type of the club-boats down to 1855. It was a lapstreak, very heavy, with a straight stem and no sheer. The width was 34 feet in the widest part; and the oars were placed in pins fastened to the gunwale. The boats used by Yale in 1852 were of a similar pattern. In 1855 the Oneida received small outriggers of wood, which was the first appearance of such arrangements in America, although they had been used in the Oxford and Cambridge races after 1846. Soon after 1855 Harvard secured an 8 oar racing boat, a lapstreak 51 feet long, with outriggers. In 1857 Harvard built the first 6-oared shell ever constructed in America. It was 40 feet long, 26 inches wide, and carried iron outriggers. The boat weighed 150 pounds—a great gain over former boats—and the material was white pine. In 1859 the Yale men brought a new shell of Spanish cedar, 45 feet long, 24 inches wide, and weighing 150 pounds. Yale carried a coxswain; Harvard carried no coxswain or rudder. This, the first racing between shells in America, was won by Harvard. The two lapstreaks also entered for the race were left behind so far that the advent of the shells marked a new era. Then came the adoption, by Harvard, of a rudder steered by the bow oar by means of wires. In 1870 Yale introduced the sliding seat, which immediately called forth a long debate as to its merits; but it was soon accepted as a positive advance in the art of rowing. In 1885 paper boats began to be used; and they are now almost universally employed.

RUNNING. Foot-races of 100, 200, and 440 yards are often won by a few inches, and the value of an inch or two in a runner's stride is of great importance. Relatively long limbs, with a short body, full chest, and small bones will win the day as against long bodies and long limbs. The small girth of the legs of runners has often been noticed. From the girth of the muscle may be obtained a correct idea of its volume, and but little idea of its length or the extent of its contraction. Length of the muscle, and not thickness, is of advantage to short-distance runners. One of the champion runners of the world is but 5 feet 7 inches in height; but he has a length of lower leg which corresponds to a man 3 or 4 inches taller and a length of thigh belonging to a man almost as large. Running records have not been preserved as carefully as the records upon other athletic sports. It may, however, be stated that for a 100 yards run a fair record is 10 to 11 seconds; for a 440 yards run, 57 seconds; for a 220 yards dash, 25 seconds. The records for running a mile differ, so that but little significance can be attached to them. The half-mile was run by Cross, of England, in 1 minute 54½ seconds in New York in 1888; the 100 yards, by Westing, in 10 seconds; the 1½ mile, by Coneff, in 6 minutes 3 seconds; the 250 yards, by Pelling, in 24½ seconds. Westing and Pelling broke the records.

SKATING, in the United States, follows at a considerable distance behind the practice of the art in Canada and in the northern countries of Europe. In fact, no Americans have yet been found who could compete successfully, either in speed or in grace, with natives of those countries. The championship of America was won in 1884 by a Norwegian, Axel Paulsen, who skated 10 miles in 39 minutes 7 seconds. Soon afterward he made 25 miles in 93 minutes 28 seconds. Both of these records were considerably in advance of the fastest time down to that date. The fastest authentic time on record in America was made by Tim Donohue, Jr., on the Hudson River, near Newburg, N. Y., in 1887. The mile was made in 2 minutes 12½ seconds.

Formerly the best skate used in America was known as the "Dutch rocker," but the wooden skate has passed away. About 1870 a skate imported from Canada, called the "Acme," proved superior to any manufactured in the United States. Now the "Club" skate appears to be the favorite. It is built upon a plate of iron or steel which fits closely to the sole of the boot; and the blade is made of the finest steel. It costs three or four times as much as the original Dutch rocker. The latter always had a groove running lengthwise of the blade; and this required continual sharpening so that the skate might take a better hold upon the ice. But with the Acme skate smooth bottoms were introduced, and grooved skates have not been manufactured since.

From about 1875 to 1890 many rinks were built in the United States for the purpose of roller-skating. This skating could be practised at all seasons of the year, but its free exercise was found to foster immorality. The public then discountenanced it and many of the States passed laws so regulating and restricting the rinks that they have been closed.

SWIMMING. Of this valuable exercise records are not frequent; and they are of little worth, because the various conditions of tide and running water are such as to make a fair record very difficult. Natatoriums are now common in all the larger cities. The former practice was to have the bottom of the building open to the bottom of a stream. But, latterly, it has been customary to build a floor that can be raised at any angle by windlasses at the four corners. This is considered much safer for the bathers. The natatoriums now float instead of being built from the bottom of the stream. An approved form consists of two pontoons running longitudinally, each 60 feet long and about 30 feet broad. The pontoons are divided by bulkheads into airtight compartments which would prevent the bathhouse from sinking in case of an accident. The pontoons are connected at the ends by stout timbers bolted and wedged with knees for braces. Upon this double boat a foundation and structure 80 feet square is erected. There is but one entrance, and that is from the outside. Small compartments, for use by the individual bathers, open by doors into the inner court. The movable floor allows any depth of water to be used, and also gives access for occasional cleanings.

For swimming the following directions are given. First, learn to duck without minding it; hold your breath and put your head under water several times whenever you bathe. The ducking will become less and less disagreeable, until the disinclination to go under water nearly or quite disappears. Some acquire the necessary indifference to being under water almost at once. When it is acquired, select a place where the water is just deep enough for the bather to sit upon the bottom with head and shoulders out. Then take a full breath, distending the lungs, and, placing the arms by the sides, lie down on your back. If unsuccessful, partially expel the air from the lungs and try again. After having found out by actual experiment how easy it is to lie down on your back under water, go out to the full length of your rope and, holding your breath, pull yourself in toward the shore, hand over hand, not letting your feet touch bottom on any account until your breath gives out or you run aground. When you can run yourself ashore with ease and certainty you will probably have discovered that most of the passage is made at or near the surface of the water, and possibly you will have learned to keep your balance and pull yourself ashore with your nose above water. When you can do this you can breathe through your nose during the passage, and as soon as you can breathe comfortably while hauling yourself ashore you are ready for the next step;

namely, try to pull yourself ashore using one hand for the rope and paddling with the other. This is not a very easy thing to do, and before you accomplish it you will find yourself paddling with both hands and kicking with both feet—that is to say, swimming. As soon as you find that you can keep yourself right side up, and your eyes and nose above water, you have learned the great secret, and swimming, with the most approved and scientific stroke, will follow according to your opportunities and ambition.

These directions are based upon the well-established fact that no one can be a confident swimmer who is disconcerted at finding himself unexpectedly under water. Therefore the first thing to be learned is to catch the breath instinctively under any and all circumstances the instant you find yourself going under water. Strangulation occurs in consequence of drawing water with the breath into the air passages, and even partial strangulation is unpleasant. The first thing, then, for the novice to learn is to instinctively keep water out of the windpipe. This can best be done by frequent voluntary duckings.

TENNIS, LAWN, is fully described in the *ENCYCLOPEDIA BRITANNICA*.

TOBOGGANING is a sport which has been recently imported into the United States from Canada. The remarkable spread of the sport in the Northern States is worthy of a brief notice. About the year 1875 the winter sports of the city of Montreal commenced to attract attention. These, including tobogganing, were made an annual feature of its social life. Since that time tobogganing slides have been erected in Saratoga, Troy, Albany, Burlington, St. Paul, and many other cities of the North.

A toboggan slide may be briefly described as follows: A frame of heavy timbers is erected to a height of from 50 to 60 feet. From one side of this frame a very steep slide, paved with ice, is arranged at an incline of about 45 degrees for perhaps 10 or 15 feet. The incline then changes so that it shall gradually approach the ground and run parallel with it. If the slide (as is usually the case) has been arranged near a hill-side, the runway is considerably longer. The object of the steep incline at first is to give the impetus to the toboggan at the start, where it is most necessary. The toboggan differs from the ordinary sled in being composed of flat boards turned up at the front end. A toboggan will carry from 2 to 6 or 8 persons. A modification of tobogganing, known in some of the Northern cities as "bobbing," is a cross between tobogganing and coasting. The "bob" consists, primarily, of two sleds joined by a long plank, upon which from 4 to 40 people can ride. In Vermont, and other of the New England States, a modified bob is used called a "traverse." This differs from the bob in that it has braces along the sides upon which to place the feet. Bobbing is practised in Albany and some other Northern cities.

WALKING was first publicly made a competitive exercise in the United States about the year 1868, when Edward P. Weston walked from New York to Chicago on a wager. The ensuing notoriety induced other walkers to take strides across the continent. Soon afterward matches were arranged within buildings upon tracks built specially for the purpose—none of them exceeding a third of a mile in circuit. In 1882 Fitzgerald made 582 miles in 6 days; and afterward Hazael made over 600 miles. These contests took place in the city of New York. In February, 1888, James Albert made 621 miles and 1320 yards in 140 walking hours, with only 19 hours and 21 minutes of the six days for resting. This record was broken in November, 1888, by Littlewood, who made 623 miles and 1320 yards within the six days. The second on the list made 605 miles in that time.

(F. G. M.)

SPOTTSYLVANIA, BATTLE OF. See **WILDERNESS.**
SPRAGUE, CHARLES (1791-1875), poet, was born in Boston, Oct. 26, 1791, his father having been one of the party that threw the tea into Boston harbor. The boy was educated at Boston, and at the age of 10, through an accident, lost the sight of his left eye. At the age of 13 he entered a mercantile house as clerk, and in 1816 became a partner. In 1820 he became teller in the State bank, and, on the establishment of the Globe bank, in 1825, he was appointed cashier, and held the office till 1865, when he withdrew from active life. He early manifested a taste for poetry, and for many years devoted his spare time to the study of the old English classics. Public notice was first drawn to him as a poet by his winning the first prize for the best prologue on the opening of the Park theatre, New York, and he achieved similar success at the opening of theatres at Philadelphia, Salem, and Portsmouth. In 1823 he won the first prize for the best "Shakespeare Ode," which was recited in the Boston theatre. In 1823 he delivered at Cambridge before the Phi Beta Kappa Society of Harvard a poem on "Curiosity" which has been considered his best production. In 1839 he pronounced the centennial ode at Boston on the 200th anniversary of the settlement of the city. Of his productions Elwin P. Whipple says: "His prologues are the best that have been written since the time of Pope. His 'Shakespeare Ode' has hardly been excelled by anything in the same manner since Gray's 'Progress of Poesy.' But the true power and originality of the man are manifested in his domestic pieces. 'The Brothers,' 'I see thee still,' and the 'Family Meeting' are the finest consecrations of natural affections in our literature." His *Prose and Poetical Writings* appeared at Boston in 1850, and other editions followed in 1855 and 1876. He died at Boston, Jan. 14, 1875.

SPRAGUE, WILLIAM BUEL (1795-1876), best known by his *Annals of the American Pulpit*, was born at Andover, Conn., Oct. 16, 1795. He graduated at Yale College in 1815, and studied theology at Princeton. He was ordained pastor of the Congregational Church of West Springfield, Mass., in 1819, and ten years later took charge of the Second Presbyterian Church, Albany, N. Y., to which he ministered for forty years. He was released from this charge in 1863 and retired to Flushing, L. I., where he died, May 7, 1876. In his early life he had published *Letters to a Daughter* (1822); *Letters from Europe* (1823); *Revels of Religion* (1832); *Words to a Young Man's Conscience* (1848), and many sermons and commemorative discourses. At length, in 1852, he began preparations for his great biographical work, to contain sketches of prominent American ministers of nearly all denominations. Though its publication was somewhat interrupted by the civil war, the work was completed in 9 large octavo volumes in 1859. Volumes I. and II. comprise the Congregationalists; III. and IV. Presbyterians; V., Episcopalians; VI., Baptists; VII., Methodists; VIII., Unitarians; IX., United Presbyterians, Lutherans, and Reformers.

SPRING, GARDINER (1785-1873), Presbyterian minister, was born at Newburyport, Mass., Feb. 24, 1785. His father, Samuel Spring (1746-1819), had been a chaplain in Arnold's expedition to Canada, and afterward pastor at Newburyport for forty years. He took part in founding Andover Seminary, and in organizing the American Board of Commissioners for Foreign Missions. Gardiner graduated at Yale College in 1803, and, after spending over a year in teaching in Bermuda, returned to New Haven to study and practise law. But he soon determined to enter the ministry, and, having studied theology at Andover, was ordained and installed pastor of the Brick Presbyterian Church, New York City, in 1810.

The early years of his pastorate were marked by frequent revivals. He took part in forming the American Bible Society in 1816, the American Tract Society in 1825, and the American Home Missionary Society in 1826. His pulpit power and influence steadily increased, and many of his sermons were published. In 1861 he was prominent in securing from the Presbyterian General Assembly (O. S.) resolutions giving moral support to the U. S. government's defence of the Union. After that year he had a colleague in the pastorate, but, though he preached less often, he retained his position till his death, Aug. 18, 1873. Among his publications were *Life of Samuel J. Mills* (1820); *Obligations of the World to the Bible* (1839); *The Power of the Pulpit* (1848); *The Mission of Sorrow* (1862); *Pulpit Ministrations* (1864); and *Personal Reminiscences* (1866).

SPRINGFIELD, the capital of Illinois, county seat of Sangamon Co., is 4 miles S. of the Sangamon river, and 185 miles S. W. of Chicago, at the intersection of the Chicago and Alton and the Wabash, St. Louis and Pacific Railroads. The State capitol, a marble building with granite portico, is 385 feet long by 296 wide, and stands in the centre of a square, which is surrounded by handsome blocks of business houses. The U. S. government offices are accommodated in a fine building. Springfield has also a fine State arsenal, 8 banks, 2 hospitals, 28 churches, 2 colleges, 3 academies, a public library, 4 daily and 10 weekly newspapers. Springfield is in a bituminous coal region, which gives rise to important industries. There are large iron-rolling mills, railroad shops, paper and woollen mills, planing and flour mills, a watch factory, and other factories. Springfield was laid out in 1822, was selected as the State capitol in 1837, and was made a city in 1840. It is governed by a mayor and a board of 18 aldermen. It has gas- and water-works and a paid fire department. Its population in 1880 was 19,743. Springfield was the home of Abraham Lincoln, and in Oak Ridge cemetery, near the city, stands the Lincoln monument, designed by L. G. Mead and costing \$264,000. Besides an obelisk, it comprises a catacomb and memorial hall.

SPRINGFIELD, a city of Massachusetts, county seat of Hampden Co., is on the Connecticut river, which is here crossed by four iron bridges and a wooden bridge to West Springfield. It is 98 miles west of Boston and is at the intersection of several railroads, which assist its commercial importance. Besides the level along the river bank, the city occupies part of an elevated plain extending eastward, and comprises three villages and post-offices besides the city proper. In the latter the streets are wide and well shaded with elm- and maple-trees. There are several public squares and a park of 100 acres. The city has a brown-stone post-office; a granite court-house, which cost \$500,000; city hall, city library; a Union railroad station, costing \$700,000; 9 banks, 3 savings banks, 2 private banks, and 3 insurance companies, a high school and 30 other schools, a cathedral and 30 churches, 3 daily and 8 weekly newspapers. The U. S. arsenal was established here in 1777 and in 1794 the armory was founded on Armory Hill. The buildings occupy a square of 20 acres, and about 400 hands are employed. During the war as many as 3400 were employed, and the daily product was 1000 finished arms. The arsenal has usually about 300,000 stands of arms. Springfield has also cotton and woollen factories, car-works, machine-shops, paper-mills, and manufactures of furniture, carriages, pistols, skates, organs, trunks, locks, picture-frames, buttons, needles, and jewellery. Springfield has gas since 1847, and electric light since 1882, and water-works, which bring a supply from Ludlow, 9 miles off, with three intermediate

reservoirs. It was settled in 1635 and was made a city in 1852. Its property is valued at \$39,861,550, and the tax-rate is 1.36 per cent. In 1885 it had 37,577 inhabitants, and has now 42,000, making it the eighth in size in the State. In the vicinity brown sandstone is quarried, and shipped over all the country.

SPRINGFIELD, a city of Missouri, county seat of Greene Co., is on the St. Louis and San Francisco Railroad, 238 miles W. S. W. of St. Louis. It is the most important town of Southwestern Missouri. It has a court-house, 15 churches, 3 banks, 2 daily and 5 weekly newspapers. Drury College, a Congregational institution, was established here in 1873. The industrial works comprise machine-shops, car-works, woollen and cotton mills. The population in 1880 was 6552, but it has since greatly increased.

SPRINGFIELD, a city of Ohio, seat of Clark county, at the confluence of Lagonda Creek with the Mad River, 81 miles N. N. E. of Cincinnati. Six lines of railway pass through the city, connecting it with Cincinnati, Cleveland, Sandusky, Columbus, Indianapolis, and more distant places. It has a fine county court-house, new government building, new city building, a handsome library structure, two opera-houses, and fine business blocks. Besides 15 public schools it has a young ladies' seminary and Wittenberg (Lutheran) College, with good building and spacious grounds, and a free public library. There are 38 churches, some of which are fine edifices, a free hospital, and children's home. Three daily and 6 weekly newspapers are published here. The city has 60 manufacturing firms, employing over 7000 workmen. The chief products are agricultural implements, among which their reapers, mowers, and graindrills (see AGRICULTURE) are especially noted. There are also produced sewing machines, bicycles, tricycles, water-wheels, iron fences, malleable iron, linseed-oil, etc. The city has good water-works, an efficient fire department, gas and electric lights, telegraph and telephone service, a park, good sewerage, street railways, and postal carrier-delivery. Springfield was laid out in 1801 and incorporated as the county seat in 1819, but its chief improvement has been since 1860. Its population in 1880 was 20,730, but it has since greatly increased. The Indian chief Tecumseh was born in this vicinity.

SPRUCE, the name usually given to that section of the botanical genus *Abies* (or, according to some botanists, to the separate genus *Picea*) the species of which are distinguished by pendant cones with persistent scales, and by the leaves being arranged all around the shoots; in distinction from the Firs, in which the cones are erect, the scales non-persistent, and the leaves placed in rows on opposite sides of the shoot. The Spruces are of slower growth than the Firs, and their wood much superior for commercial purposes, it being soft but tough, and well adapted to many uses. The Spruces are also often of handsome form and foliage, and several species are highly esteemed as ornamental trees.

In the eastern United States and Canada there are three species of considerable commercial importance, *Abies Canadensis*, the Hemlock Spruce; *Abies nigra*, the Black Spruce; and *Abies alba*, the White Spruce. (For a description of these species, see FIR in the ENCYCLOPEDIA BRITANNICA.) The Rocky Mountain and Pacific coast regions possess several species, most important among which is *A. Engelmanni*, the characteristic species of the mountains of Colorado. This is a large tree, from 75 to 150 feet in extreme height, and 3 to 4 feet diameter, its range extending through the Rocky Mountains to British Columbia and to Oregon. It is a handsome tree, with timber similar to that of *A. nigra*, covers the mountain-slopes from 5000 to 11,500 feet elevation, and at the medium height forms in Colorado

extensive forests of considerable density and great beauty. At its extreme elevation it is reduced to a prostrate shrub, which is, however, loaded with cones. *P. Engelmanni* is the most valuable timber tree of the central Rocky Mountain region, being much used for fuel, charcoal, and lumber, while its bark is rich in tannin.

A. Litchensis, the tide-land spruce, extends from Alaska to California, and forms extensive forests, from 10 to 50 miles wide, near the mouth of the Columbia River. It is a large tree, attaining a height of 140 to 180 feet, and 7 to 15 feet diameter, and is of great economic value, its wood being used for construction, fencing, boat building, cooperage, etc. *A. pungens* is a rare and local species, extending from the Wind River Valley to the mountains of Wyoming, Colorado, and Utah. It never forms forests. Among the species which have been classed as spruces may be named the huge Douglas Spruce,

Norway Spruce.

which in its extreme growth is among the tallest trees known, it being said to occasionally, in Oregon, attain a height of 300 to 350 feet. Recent botanical authorities, however, remove this species from the genus *Abies*, and class it as *Pseudotsuga Douglasii*, it having peculiarities of seeming generic value which approach those of the Hemlocks. In addition to the native Spruces of America, several exotic species have been introduced as ornamental trees, principal among these being the Norway Spruce, *A. excelsa*, which in form and foliage is one of the handsomest of the conifers. (C. M.)

SPURGEON, CHARLES HADDON, eminent Christian preacher and worker, was born at Kelvedon, Essex, England, June 19, 1834. His father John and grandfather James had been pastors of Independent churches. With the latter Charles spent his childhood, already evincing a serious disposition and being pointed out as likely to be a successful minister. Returning to his father's house at Colchester, he attended school there, and when only fifteen be-

came an usher at Newmarket. In 1850 he became a Baptist, and soon began to preach with such force that in 1852 he was made pastor of a church at Waterbeach. In the next year he was called to supply New Park Street Chapel, London, and in a few months a sermon of his was printed, thus inaugurating a practice which has resulted in the circulation of millions of his discourses. The chapel, proving too small for the increased congregation, was enlarged, and in 1861 the Metropolitan Tabernacle was opened, having seats for 5500 persons. Though its cost exceeded \$150,000, it was free of debt. In connection with this church there are numerous missionary, educational, and philanthropic agencies. The Pastors' College, intended to fit young men for ministerial work, began in 1855, and has a special building, erected in 1874. The Stockwell Orphanage sprang from a gift of £20,000 made by a lady to Spurgeon for this work. At first boys only were admitted, but since 1879 girls also are received. There are now about 240 boys and 230 girls supported, the most needy having the preference. The church has also its almshouses and day-school, and carries on colportage in the villages of England. Mr. Spurgeon has an efficient helper in his wife, to whom he was married in 1856, and his brother, James Archer Spurgeon (b. 1837), has been his associate in the pastorate since 1863. His twin sons, Charles and Thomas, have become Baptist preachers, the former at Greenwich, England, the latter at Auckland, New Zealand. Spurgeon's publications comprise, *The New Park Street Pulpit*, *The Metropolitan Tabernacle Pulpit*, *The Treasury of David*, a commentary on the Psalms (7 vols.), *Lectures to my Students*, *John Ploughman's Talk*, and *John Ploughman's Pictures*. The last two, homely in style and pungent in matter, have attained a circulation of 350,000 copies. Mr. Spurgeon's religious monthly magazine, called *The Sword and Trowel*, gives information of the various enterprises in connection with his church. The power exerted by Spurgeon, both in the pulpit and through the press, has been abundantly acknowledged not only by those favorable to his methods but by those indifferent and hostile. The *London Times* has been led to ask why St. Paul's and Westminster Abbey should remain comparatively empty while this dissenter should gather around him 10,000 people every Sunday. The *Daily Telegraph* and the *Saturday Review* have borne testimony to his efficiency. His success is due to his intense earnestness and sincerity, assisted by his simple, idiomatic language and his impressive delivery. Fully convinced of the truth of his utterances, he presses the message of Christianity on the hearts of the people.

SQUASH, the name commonly given to several species of the gourd family, genus *Cucurbita*, the title being derived from the final syllable of the Indian name for the plant, *Askutasquash*. The words squash and pumpkin are used somewhat indiscriminately in the United States, large varieties of the squash being ordinarily called pumpkin, without attention to specific characters. It is very difficult, indeed, to define the species of squashes, or to trace the cultivated varieties to the original species, the plants hybridizing so readily as to confuse all distinctions. The squashes are said to be of wider variety in kinds, fitted for more varied uses, and found in a better state of perfection under all conditions of weather, than perhaps any other garden product. Being of tropical origin, their growth is consummated during the summer, yet the fruit of the late varieties can be kept, with a little care, through the winter, and until the following May. They are all of luxuriant and vigorous growth, and will do well in almost any soil, though they respond very readily to generous fertilization. They are, next to Lima

beans, the latest vegetable to be planted, light soils being best suited to their cultivation.

There are two broad varieties of squashes, the bush squashes, of early summer ripening, and the late or winter squashes. The vines of the bush or early varieties have lost much of their running habit, and grow in a somewhat bush-like compactness, while the late varieties have vines of 12 feet or more in length, which send down secondary roots at their joints. In planting, the bush squashes are sown in hills 3 or 4 feet apart, the running squashes 6 to 8 feet apart. Eight or ten seeds are sown in each hill, the plants being afterward reduced to three or four of the strongest. Squashes are grown extensively for market, and the early varieties are raised in large quantities in the vicinity of Norfolk, Charleston, and Savannah for shipment to the North, reaching market two or three weeks before the Northern squashes are ripe.

It is not positively known that there are any species of squashes native to the United States, though there is reason to believe that this is the case. Roger Williams and other early writers of New England speak of the general culture of some varieties by the Indians. One species, *C. ovifera*, is found wild in Texas. It is cultivated principally for ornamental purposes, under the names of mock orange, orange gourd, etc., and is occasionally eaten young, as the egg-squash. Gray thinks it may be the original of all the crook-necked squashes, the vegetable marrows, and even the common pumpkins. There are very many varieties of squashes in cultivation, though it is difficult to keep any kind pure, on account of their readiness of intercrossing. Of the bush varieties those most commonly grown bear a fruit of partly hemispherical shape, with an expanded and flattened edge which is deeply and regularly scalloped. These vary considerably in color, are the earliest to ripen, and are planted almost exclusively for the first crop, while their hard rind adapts them well to shipment. The Summer Crook-neck is highly esteemed, and the best in yield of the summer varieties. It is about 8 inches long, tapering and curved toward the stem, the skin bright yellow in color, with warty protuberances. The Boston Marrow, which ripens about ten days after the above, has an orange-yellow, very thin rind, and is of unsurpassed flavor. The fruit is egg-shaped, with both ends pointed.

Of the fall and winter varieties the Essex Hybrid is of excellent flavor and is unexcelled in winter-keeping qualities. The Hubbard is far more extensively grown as a late variety than any other. It is of large size, often weighing 9 or 10 lbs., of bluish-green color, and of superior quality. In some of the Eastern States the Winter Crook-neck is largely grown for winter supply. The Mammoth Chili is a variety which attains an immense size, often weighing as much as 200 lbs. It is excellent for all purposes. In England the favorite variety of the squash is that known as the Vegetable Marrow, which is distinct in character from all the preceding. The fruit varies considerably in size, ranging from 9 to 18 inches in length, and from 4 to 6 inches in diameter. The skin is of a greenish-yellow color, the flesh white, soft, and of a rich flavor. We have named here but a few of the very many varieties of the squash, but the above are those most widely grown and highly esteemed at present. They are used largely on American tables, cooked as a vegetable, as a constituent of pies, and prepared in other modes, and form a very important member of our food products. (C. M.)

SQUIER, EPHRAIM GEORGE (1821-1888), traveller and archæologist, was born at Bethlehem, N. Y., June 17, 1821. In youth he worked on a farm, taught school, then edited country newspapers, and

studied engineering. Having removed to Ohio he became interested in the Indian mounds of that State, and with Dr. E. H. Davis undertook an exploration of them, whose results were published by the Smithsonian Institution. He next published *Aboriginal Monuments of the State of New York* (1849). In 1848 he was sent by the U. S. government as chargé d'affaires to the republics of Central America. His observations of this region and its remarkable aboriginal architecture were recorded in several volumes, among which are *Nicaragua: its People, Scenery, and Monuments* (1852). In 1853 he returned to survey a route for an interoceanic railroad, which, however, was never begun. He published *The States of Central America* (1857), which was revised in 1870; and a work on *Tropical Fibres* (1861). In 1863 he was sent to Peru as U. S. commissioner and explored the remains of the Inca monuments, but after his return to New York his labors in the preparation of an exhaustive work on the subject were interrupted by a mental disorder. After an interval of years he was able to publish, *Peru: Incidents and Explorations in the Land of the Incas* (1877). Still later he was again attacked by the mental disorder and unfitted for work. He died at Brooklyn, April 17, 1888.

STAMFORD, a borough and town of Connecticut, in Fairfield county, on Long Island Sound, and on the New York, New Haven and Hartford Railroad, 34 miles N. E. of New York. The harbor will accommodate vessels of 8 feet draught, and there is daily steam boat communication with New York. The town-hall is a fine building which cost \$140,000. There are 10 hotels, 2 national banks and 2 savings banks, 4 weekly newspapers, 8 churches in the borough, and 12 more in the town. Besides manufactures of drug-extracts, hats, Yale locks, and post-office outfits, there are iron and bronze foundries, sash and blind factories. The borough is lighted with gas, and has water-works and small parks. Its property is valued at \$10,000,000, its public debt is \$150,000, and its ordinary yearly expenses about \$100,000. It was settled in 1641 and incorporated in 1830. For two hundred years it preserved the aspect of a typical Puritan village, but since 1850 it has become more cosmopolitan. The town has an area of 10 square miles, of which the borough occupies one-sixth. Many citizens of New York have summer residences here. The town had in 1880 a population of 11,297.

STÄMPFLI, JAKOB (1820-1879), a Swiss statesman, was born in the province of Berne in 1820. He was of humble origin, but by energetic persistence acquired a good education. He studied law at Berne, became an advocate in 1843, and soon after entered actively into politics, becoming a leader of the radical party about 1845. He was elected president of the canton of Berne in 1849, and of the republic of Switzerland in 1858. The reforms introduced through his influence were the establishment of direct taxation and the abolition of all feudal burdens, while he vigorously opposed the influence of the Jesuits. In 1872 he was chosen one of the members of the Alabama arbitration commission, and gave his vote in favor of the United States. He died, May 15, 1879.

STAMP ACTS. See REVOLUTION, AMERICAN.

STANDISH, MILES (or MYLES), the Pilgrim-soldier, was born about 1584, in Lancashire, England, and claimed to be descended from the rightful heirs of Duxbury Hall, Lancashire. Froissart tells how, in the time of Richard II., the rebel Wat Tyler was slain by a "squyer of the Kynges called John Standyshe" who received knighthood for the deed. Longfellow refers to the feat in his "Courtship of Miles Standish": "One of my ancestors ran his

sword through the heart of Wat Tyler." While yet a youth Standish entered the English army in the Netherlands and rose to the rank of captain. Though not a member of the Leyden church or congregation he accompanied the Pilgrims to Cape Cod Bay, New England, on board the Mayflower, whence on Nov. 21, 1620, sixteen armed men, "Everyone his musket, sword, and corslet, under the command of Captaine Myles Standish were despatched ashore on a second exploration." No one has described the captain's appearance and character so graphically as Longfellow:

"Short of stature he was, but strongly built and athletic,
Broad in the shoulders, deep-chested, with muscles and sinews
of iron.
Somewhat hasty and hot (he could not deny it), and head-
strong,
Stern as a soldier might be, but hearty and placable always,
Not to be laughed at and scorned, because he was little of
stature,
For he was great of heart, magnanimous, courtly, courageous."

During the first winter at Plymouth he lost his wife, Rose, and tradition tells that he employed his friend, John Alden, to negotiate his marriage with the winsome Priscilla Mullins, but the maid's suggestion, "Why not speak for yourself, John?" resulted in her marriage with the envoy. Standish was the champion, *par excellence*, of the infant settlement, defending it against the open and secret hostilities of the Indians. In 1622 a new colony was founded at Wessagussett (now Weymouth), and the Massachusetts Indians planned to destroy it. The plot was revealed by a friendly Indian, and Standish, with only 8 men, set out to its relief. By the counsel of their native well-wisher Standish decoyed the two chiefs, along with a half-brother of one of them, into a room, and there, after a desperate struggle, slew them. A battle followed, and the Indians fled. The head of Wituwamat, one of the chiefs, was set up at Plymouth, and this, with Standish's victory, struck terror into the savages. In 1625 he revisited England as agent for the colony, and returned next year with supplies. He then settled Duxbury—giving that name to the place after the English home of his race—and for the remainder of his life held the office of magistrate or assistant of that town. Plymouth despatched a vessel and force under Standish to compel the French to surrender Penobscot, from which, in 1635, they had driven away a party of Plymouth men, but the expedition proved a failure. In addition to being the military head of the colony, Standish was its counsellor in civil matters, and for many years its treasurer. Tradition says his second wife, Barbara, was a younger sister of his first wife, Rose. In 1877 a portrait of Standish, painted on a panel, with date 1625, and bearing his name and age (38), was discovered in a picture-store in Boston. It is now to be seen in Pilgrim Hall, Plymouth, where one of his swords is preserved, another being in the cabinet of the Massachusetts Historical Society. He died at Duxbury, Oct. 3, 1656, leaving a widow and four sons to whom, by his will, bearing date March 7, 1655, he left his property, valued at £350. A granite monument (founded in 1872) is erected to his memory on Captain's Hill, Duxbury, and is surmounted by a statue of the hero, "the first commissioned military officer of New England." (J. H.)

STANFORD, LELAND, railroad constructor and senator, was born at Watervliet, N. Y., March 9, 1824. His early life was spent on a farm, but, having studied law, he was admitted to the bar and began practice at Port Washington, Wis. In 1852 he removed to California and engaged in gold mining in Placer county. In 1856 he established a mercantile business in San Francisco, and accumulated a large fortune. In 1860 he was a delegate to the Republican national convention at Chicago. He was a

prominent promoter of the Pacific railroads, and in 1861 became president of the Central Pacific Railroad. He was elected governor of California in the same year. His energy and force of character were fully shown in the construction of the Pacific Railroad over the mountains in 1869. Subsequent years were devoted to the development of the business of the road and to the promotion of the material interests of California. In 1885 he was chosen U. S. senator. In memory of his only son he has given \$20,000,000 for the endowment of a university at Palo Alto, Cal. The corner-stone was laid, May 14, 1887, and the buildings are expected to accommodate students in 1889.

STANLEY, DAVID SLOANE, general, was born in Cedar Valley, Ohio, June 1, 1828. In 1852 he graduated at West Point and was brevetted 2d lieutenant in the Second Dragoons, and detailed for service in the survey of a railroad route along the 35th parallel. From 1855 till 1861 he served as a cavalry officer, almost constantly on the frontier, taking part in engagements against the Cheyennes and the Comanches. For a successful fight against the latter, near Fort Arbuckle, he was complimented by Gen. Scott in general orders, and in 1861 promoted to a captaincy. On the outbreak of the civil war he was sent to the field of active operations in Missouri, where he was engaged in several actions, and in September, 1861, was nominated brigadier-general of volunteers. At New Madrid he led a division, and the general in command reported that he was "especially indebted to General Stanley for his efficient and untiring zeal." He commanded the second division of the Army of the Mississippi at the capture of Island No. 10, and in this capacity took part in most of the skirmishes around Corinth and in the battle of Farmington. He was in the battle of Iuka (Sept. 19), for his conduct in which he was commended by Gen. Rosecrans, and in that of Corinth (Oct. 3-4), where he was exposed to the severest attack of the enemy, but stood fast when other parts of the line gave way. In November, 1862, he was made chief of cavalry in the Army of the Cumberland, and on the 29th promoted major-general of volunteers. He was in active service at the battle of Stone River, in the Tullahoma campaign, including the battle of Shelbyville, and in the many minor engagements of that army. He was in command of the Fourth Army Corps in Sherman's Atlanta campaign, and took part in the battle of Jonesboro, where he was wounded. During the month of October his command was engaged in following Hood, till on the 27th it was detached from Gen. Sherman's force and ordered to strengthen Gen. Thomas, who had been despatched to Nashville to resist the invasion of Tennessee. On his march toward Nashville he was engaged in frequent affairs, distinguishing himself particularly in the action at Spring Hill. On the Fourth and Twenty-third Corps (of which he was now in command) arriving at Franklin, Nov. 30th, it made a stand, and a desperate hand-to-hand conflict ensued, in which he was severely wounded; refusing, however, to leave the field till a notable victory had been gained. He received frequent promotions, and for his skill and bravery here was brevetted major-general in the regular army. After being disabled for two months he rejoined his command, and, after the war, led it to Texas. In February, 1866, he was mustered out of the volunteer service and resumed his command in the regular army, as colonel of the Twenty-second Infantry. In 1872-73 he was in command of the Yellowstone expedition, and his favorable reports in regard to the hitherto unknown Dakota and Montana did much to promote emigration thitherward. In 1874 he was with his regiment at the lake stations; in 1879 he moved to Texas, and effectually checked

Indian raids in the West. In 1882 he was ordered to Santa Fé, and placed in command of the district of New Mexico. In March, 1884, he was assigned to the Department of Texas, with the rank of brigadier-general in the regular army.

STANLEY, HENRY MORTON, explorer, was born near Denbigh, Wales, in 1840. His name was then John Rowlands, and at the age of three he was sent to the poor-house at St. Asaph, where he stayed till he was thirteen. He was then employed as a teacher at Mold, Flintshire, but a year later shipped as a cabin-boy for New Orleans. There a merchant named Stanley gave him employment and eventually adopted him. But the merchant died intestate, and his property passed to other heirs. Stanley then led a roving life among Indians and California miners until the civil war broke out. He enlisted in the Confederate army, but, being soon taken prisoner, offered to take service on the other side. He was sent to the iron-clad Ticonderoga, and there became acting ensign. At the close of the war he went to Crete as correspondent for the *New York Herald*, but soon left and travelled in Turkey and Asia Minor. Returning, he visited Wales, and gave a dinner to the poor-house children at St. Asaph. In 1867, after a visit to the United States, he went as a *Herald* correspondent to Abyssinia. By sending to London the news of Lord Wolseley's victory before the official despatches arrived, Stanley attracted universal attention to his merits. In 1868 he was employed in reporting the war in Spain. In 1869 Mr. James G. Bennett, the proprietor of the *Herald*, conceived the idea of sending the adventurous Stanley into Central Africa in search of Dr. Livingstone, who had been reported to be killed in 1866, but whom Mr. Bennett believed to be still alive. Stanley went first to the East, visiting Constantinople, Egypt, Jerusalem, and crossing Persia to India, which he reached in August, 1870. Thence he sailed in October for Zanzibar, having decided to follow in Livingstone's track. He organized an expedition of 192 men, divided into five caravans, the first of which started inland on February 18, 1871, and the last of which he accompanied on March 21. His objective point was Ujiji, and he had resolved to reach Unyanyembe, the half-way house, within three months. In the middle of April he met an Arab chief, bound eastward, who informed him that Livingstone was at Ujiji. During the first month much of Stanley's route lay through the jungle, so that his average day's march was only four miles, while the carriers and other natives hired to accompany him frequently gave trouble or tried to escape. Still worse were his difficulties with the Englishman and Scotchman whom he had engaged as his chief assistants. But, in spite of fever and insect-plagues, as well as the troubles from treacherous followers and extortionate chiefs, he pushed on, and in June reached Unyanyembe. Owing to his sickness and a tribal war he remained in this vicinity till the end of August, though he heard again that Livingstone was at Ujiji, 400 miles distant. Across the fertile regions of the interior, peopled by naked savages, he toiled on, paying tribute to chief after chief for permission to pass his little district. At last, on Nov. 10, 1871, he sees the port of Ujiji on the great lake Tanganyika. At his order his band fire their guns and display the American flag, and march into the town. Livingstone's servants soon salute him, and conduct him to the object of his toilsome search. The veteran missionary and the adventurous correspondent exchange greetings. They spent four months together, but Dr. Livingstone refused to return to Europe, as his work of exploration was not yet done. He accompanied Stanley on his return as far as Unyanyembe, to which place stores had been forwarded for both parties. Though

floods greatly impeded the way, Stanley pressed on, and in May, 1872, was again in Zanzibar, where he found another expedition, organized under the auspices of the Royal Geographical Society, making preparations to start. As, however, the immediate object of finding Livingstone had been already accomplished, this expedition was abandoned for the time, but was taken up again by Lieut. Verney L. Cameron. (See AFRICA in this work.) Stanley arrived in England in July, 1872, and gave an account of his expedition before the British Association in August. Honors of all kinds were abundantly bestowed upon him, and in November he published his narrative, *How I Found Livingstone*. Before he left Africa Stanley had despatched a caravan with stores for Livingstone, but it spent five months in reaching him. Then the veteran resumed his work, but the country he explored was flooded and he eventually succumbed to dysentery, dying on May 1, 1873.

Stanley's next famous expedition is described under AFRICA. In this, starting again from Zanzibar in the autumn of 1874, he turned off to Victoria lake, which he thoroughly explored, then made his way to Ujiji, crossed to the Lualaba river, and, there embarking, proved its identity with the Congo by sailing down that mighty stream to the Atlantic Ocean. He reached the coast in August, 1877, after perils far surpassing those of his first famous expedition. His second heroic enterprise and the wonderful geographical discoveries which were then accomplished are narrated in *The Dark Continent* (1878). He went again to Africa in 1879 under the auspices of the African International Association, of which the King of Belgium was the chief patron, to explore the basin of the Congo river (*q. v.*). In the course of four years Stanley had established trading stations along the river for a distance of 1400 miles, and founded a government for the region.

Toward the end of 1886 Stanley undertook an expedition, partly at the expense of the Egyptian government, for the relief of Emin Pacha, who had seized the southern part of the territory claimed by Egypt. Leaving England in January, 1887, he gathered in Zanzibar a force consisting of 620 natives of that country, with 74 other Africans and 9 Europeans. He also had the help of Tippo-tip, the greatest slave-dealer of Central Africa. King Leopold of Belgium had furnished several steam-boats for use on the Congo. Stanley embarked on these at Stanley Pool on April 30, 1887. Since that time there have been rumors of his death, and again of his safety, but the facts are not yet positively known.

STANTON, ELIZABETH CADY, an earnest advocate of "Woman's Rights," was born at Johnstown, N. Y., Nov. 12, 1816. Her father, Daniel Cady, was an able and learned lawyer, who for years held the office of judge in Fulton county. His daughter, while still a child, spent much time in his office, where she heard many instances of the unjust discrimination of the laws against the property rights of women. Her indignation was early aroused by this, and was increased by the little consideration shown to girls as compared with boys. Her father manifested a superior regard for his son, and when the latter died was inconsolable, though he had five daughters. "I wish you were a boy," he said with a sigh to his daughter Elizabeth. "Then I will be a boy, and will do all my brother did," she replied. In pursuance of this resolution she determined to learn Greek, and the art of managing a horse, conceiving that learning and courage were the principal manly characteristics. She studied Greek, Latin, and mathematics, winning in the first-named study a Greek Testament as a prize, and afterward graduated in the Johnstown Academy at the head of her class. Her heart was set on entering Union College, where her brother

had been educated, and on learning that girls would not be admitted her vexation and indignation were great. She afterward studied at Mrs. Willard's Seminary in Troy. On reaching maturity the thoughts which had been fostered in her girlhood showed themselves in the life of the woman. She became an ardent advocate of the anti-slavery cause, and in 1839, when 23 years of age, was married to Henry B. Stanton, an eloquent anti-slavery orator.

Her husband had been chosen as a delegate to the World's Anti-slavery Convention, which met at Freemasons' Hall, London, June 12, 1840, and thither the newly wedded couple proceeded. Many women-delegates had been sent from America to the convention, but owing to prevailing notions about women, they were not permitted to take part in its deliberations. This exclusion excited much indignation, and added to Mrs. Stanton's feeling of the injustice done to her sex. While here she formed a warm friendship with Lucretia Mott, one of the most highly respected advocates of the reform upon which she had set her heart. Among the Englishwomen excluded from the convention were Elizabeth Fry, Mary Howitt, and Amelia Opie. On her return to America Mrs. Stanton resolved to devote her life to resisting the injustice shown, in several forms, to her sex; and in pursuance of this resolution she called, in June, 1848, at her own instance, a public convention of women at Seneca Falls, N. Y., in which city she then resided. This was the pioneer "Woman's Rights Convention" (known under that name), but Mrs. Stanton went in her views beyond all the other delegates in resolving to include woman's suffrage among the rights demanded. Her husband and Lucretia Mott strongly objected to her purpose in this direction, and at the opening of the convention she found only one delegate, Frederick Douglass, to support her novel demand. She had never before spoken in public, but developed an excellent ability in oratory, and, aided by Mr. Douglass, carried all her resolutions, that demanding the ballot included, through the convention. The announcement of this convention made a great sensation throughout the country. All the papers commented upon it, generally with ridicule, but Mrs. Stanton went persistently to work to advocate her views before the women of America. Two years after the convention Miss Susan B. Anthony, who had at first treated the demand for the ballot as ridiculous, became her friend and co-worker, and together they have spent their lives in ardent advocacy of this cause.

In 1866 Mrs. Stanton, then living in New York city, offered herself as a Congressional candidate to the voters of the 8th district. Out of 23,000 votes cast she polled exactly 24. In 1868 she, in conjunction with Parker Pillsbury, Miss Anthony, and others, started *The Revolution*, a journal in the interests of women's rights. This journal was finally merged in *The Liberal Christian*, an organ of Unitarianism. After giving up her editorship of *The Revolution* Mrs. Stanton devoted herself for 14 years to public lecturing. She is a happy and ready speaker, and by her advocacy did much toward the advancement of the cause she had so much at heart.

Apart from this exhausting work she compiled, in her residence at Tenafly, N. J., a *History of Woman Suffrage* (3 vols. of 1000 pages each), embracing documentary evidence and biographies of its leading advocates. In 1882 she went to France on a visit to her son and his wife, and in 1883 held conferences in England with John Bright and others on her favorite theme. Mrs. Stanton has a son living in France, and a daughter residing in England, and has in all five sons and two daughters. The social reforms which she advocates have made remarkable progress during the forty years which have elapsed since the first convention at Seneca Falls. The property rights of

women have been placed on a level with those of men in some States, and have everywhere improved, while the demand for the ballot has gained too wide a circle of advocates to be any longer considered ridiculous, and has been granted in regard to school-board elections in some States, and in all municipal elections in the State of Kansas.

Her husband, HENRY BREWSTER STANTON (1805-1887), lawyer and journalist, was born at Pachaug, Conn., June 27, 1805. He removed to Rochester, N. Y., in early life, and engaged in journalism and politics. After being clerk of Monroe county for three years he went to Lane Theological Seminary at Cincinnati, in 1832, and there took part in the anti-slavery movement. He devoted years to this cause, and in the meantime, having married Miss Cady, went with her to London in 1840, and then made a tour in Great Britain, Ireland, and France. In 1847 he settled at Seneca Falls, N. Y., and was admitted to the bar, but was still active in urging temperance and other social reforms, as well as in anti-slavery work. He published *Reform and Reformers in Great Britain and Ireland* (1849). His chief work was done through the daily press, to which he was a constant contributor. He died in New York City, Jan. 14, 1887. Soon afterward a volume of his *Random Recollections* was published. (C. M.)

STARCH. A very considerable variety of plants yield commercial starch, though the principal supply is obtained from wheat, maize, rice, and potatoes. The manioc-root is the source of the useful nutrient variety known as tapioca; the root of several species of *Moranta*, of arrowroot; and the pith of very many of the palms, of sago. These latter, however, are tropical productions, and the ordinary starch of commerce comes in great part from the substances first named. Corn- or maize-starch is a product of American inventive industry, and was first produced in 1842. Previously wheat, barley, rice, and potatoes had yielded the world's supply of starch. Potato-starch was first made in the United States in 1802, the industry being introduced by John Biddis, of Pennsylvania. It in time became an important product, and a large number of starch factories were built, especially in the cotton-manufacturing districts, the starch being largely consumed in this industry. A number of wheat-starch factories also were built. In Europe wheat constituted the principal source of starch, the product being very considerable, particularly in England and France, whose cotton factories consume a large percentage of the supply. Among the several substances which have been used abroad as starch producers may be named horse-chestnuts, which have been employed for this purpose in France. The bitter principle is removed by the use of sodium carbonate.

In 1842 Thomas Kingsford, superintendent of the wheat-starch factory of W. Colgate & Co., in New Jersey, began to experiment with Indian corn, and soon satisfied himself that this grain was well adapted to serve as a superior commercial source of starch. His conviction was communicated to others, and some capitalists built a factory for him at Oswego, N. Y., in 1848, this location being chosen from the ease of getting a large supply of corn from the West by water-carriage, while it was comparatively convenient to the great commercial and manufacturing centres. The industry prospered from the start, and the factories have grown until they cover 10 acres of ground-surface, treat over a million bushels of corn annually, and yield an annual product of more than 20,000,000 lbs. of starch. The great prosperity of the Oswego factory gave instigation to another great concern, the Duryea Brothers' corn-starch manufacturing establishment at Glen Cove,

Long Island, which was founded in 1858, and has at present a yield nearly or quite equal to that of the Oswego factories. These two concerns are now the largest starch-manufacturing establishments in the world. As early as 1860 they had brought to an end the importation of European starch, and soon after they began to compete with the factories of Europe for the starch commerce of the world. They have received the first prizes at international exhibitions, and the demand for their product has steadily grown, the exportations of American starch increasing from 1,000,000 lbs. in 1864 to 7,400,000 lbs. in 1887.

Corn-starch is made in the United States by soaking the corn in water containing caustic soda and hydrochloric acid, to dissolve the gluten, grinding, washing on sieves, and finishing by various processes. Each of the two great establishments employs its own methods, and no effort is made to recover the gluten as a food product, as in the European wheat-starch factories; but this, with other by-products of the grain, is sold as food for domestic animals. The starch is prepared in three forms, for three separate purposes. The first is that known as "Maizena," in England as "prepared food," being pulverized corn-starch intended for culinary purposes, and as food for infants and invalids. The second is the refined starch prepared for laundry use; the third, sizing starch for use in cotton factories and other industries.

The success of the factories named has led others into the business, and there are many smaller corn-starch factories now established. The establishment of this industry, however, has not done away with the production of wheat-starch, which is made in the United States on a considerable scale. Potato-starch is also largely manufactured, there being several factories at Stowe, Vt., and Watertown, Mass., some of which consume 20,000 bushels of potatoes annually, the yield averaging 8 lbs. of starch to the bushel. Rice-starch is largely manufactured in England, France, and Belgium, but not in the United States. In regard to the statistics of the American starch industry, there exist no general ones later than those of the census reports, and these are lacking in detail. In 1870 the number of starch factories in the United States were reported as 195, with a total product valued at \$5,995,000. In 1880 the factories had decreased in number to 139, but the product had increased to \$7,477,742. This was principally produced in three States, the yield of New York being \$3,328,102; of Ohio, \$1,754,710; and of Indiana, \$1,276,880. No other State produced largely. The business is steadily increasing, and is probably destined to attain a great development in the future, the immense yield of corn in this country giving an almost unlimited supply of material. The proportion of starch in the various grains is the following: Maize, 60 to 80 per cent.; wheat, 60; rye, 60; oats, 46; barley, 57; rice, 61. Potatoes yield 62 per cent. Of these various substances the high yield of maize seems to adapt it particularly to starch production. As to the uses of starch, the following are the principal: It is used for stiffening cotton and linen cloths, and as a sizing for paper and various other articles; for making paste, hair powder, dextrine, glucose, etc.; in medicine, to dilute and otherwise modify various articles of the materia medica; in surgery, in the preparation of splints and bandages; in the chemical laboratory, for the detection of iodine; for stiffening purposes in the laundry; and as a nutritious and agreeable article of food, for which its use is rapidly increasing. For the last-named purpose corn-starch is of high value. (C. M.)

STARK, JOHN (1728-1822), general in the Revolutionary war, was born at Londonderry, N. H.,

Aug. 28, 1728. In 1736 his father removed to Derryfield, now Manchester, in that State, where young Stark was employed in farming, with intervals of hunting, till April 28, 1752. On that day, while out hunting, he was taken prisoner by a party of St. Francis Indians, in whose hands he remained a captive for six weeks, being finally set free on the payment of \$103 ransom. While with the Indians his frequent exhibitions of courage and independence of spirit made him very popular, and he was adopted into the tribe. In 1755 he was appointed lieutenant in Rogers' company of rangers, with which he served in the campaigns of that and the following year. In January, 1757, the corps to which he was attached, while returning from an expedition, was attacked by a strong body of French and Indians near Ticonderoga and a sanguinary conflict ensued, ending in the repulse of the colonists. The management of the retreat fell to him, and it was effected with great skill and prudence. Soon afterward he was made captain of rangers, and in 1758 took part in Abercrombie's attack on Ticonderoga. In the following spring he joined Amherst's army, and was present at the reduction of Ticonderoga and Crown Point.

At the end of the French war Stark returned to his farm, and remained there till the beginning of the Revolutionary troubles, when he was made a member of the Committee of Safety, and on learning of the battle of Lexington immediately repaired to Cambridge. Here he was made colonel of a regiment of New Hampshire troops, and took part with them in the battle of Bunker Hill, where his men were stationed behind a rail fence at the left of the line. They held their ground firmly, and repeatedly repelled the enemy with great loss, but were forced to retreat when the other portions of the line were taken. At the close of the campaign in the North, in 1776, he joined Gen. Washington, and in the battle of Trenton commanded the vanguard of the army. In the subsequent engagement at Princeton he played an active and prominent part. In the promotions that followed, however, Stark was overlooked and, feeling aggrieved, he resigned and returned to his farm in April, 1777. He was not left long at rest. The advance of Burgoyne from Canada began in June, and fort after fort was taken as he advanced south by the Lake Champlain and Lake George route. The council of New Hampshire at once commissioned Stark to raise a force to guard the frontier, and he quickly found himself again in active service. Burgoyne sent a detachment under Col. Baum to seize the supplies which the Americans had collected at Bennington, Vt. Gen. Stark marched rapidly to save these stores, and, finding Baum intrenched at a point near Bennington, attacked with great energy. It was at this time that he inspired his raw troops with the speech that has become historic: "There are the red-coats; we must beat them to-day, or to-night my wife sleeps a widow." His spirit was seconded by the valor of his men, the regulars were severely defeated, and a second force that was marching to Baum's assistance suffered the same fate, the British loss in these two actions exceeding 600 men. Yet more important was the saving of the stores, of which Burgoyne stood sadly in need, and the want of which aided in the eventual total collapse of his expedition.

For this gallant action Congress voted thanks to Gen. Stark on Oct. 4, 1777, though it had just before passed a vote of censure on him for disobeying Gen. Lincoln's order to march to the west of the Hudson, a step which would have left Baum's raid unopposed. He was commissioned major-general, and in September joined Gates and contributed to the success of the campaign. In 1778 he was placed in charge of the Northern Department at Albany, and in October of that year joined Gates in Rhode Island.

In May, 1780, he joined the army at Morristown, and was present at the battle of Springfield, being again placed in command of the Northern Department in the spring of 1781. This ended his army service, and he returned to his farm at Manchester, N. H., where he died, May 8, 1822, Congress having voted him in 1818 a pension of \$60 per month.

STATE-MILITIA. The militia of each of the States of the Union is an essentially State institution regulated by State laws. But by the provisions of the Constitution of the United States and the laws of Congress enacted to carry those provisions into effect, the militia of each State is, to a certain extent, subject to Congressional regulation and, under certain circumstances, is required to render service to the general government. This twofold relation—on the one hand to the State, on the other to the Union—gave rise, during a considerable portion of our national history, to much discussion, to angry disputes, and often to serious embarrassments. Partly by the logic of events, partly by the decisions of our highest judicial tribunals, these questions may all be regarded as now practically settled. A brief sketch of the history of the militia of the United States, of the nature of the questions above referred to, and of the manner of their settlement is necessary to a full understanding of the character and availability of the militia as a military force and of its present condition and strength.

When the Continental Congress proclaimed the independence of the colonies in the famous Declaration, the only military force of which it could avail itself in order to maintain that declaration was the militia. All the regular soldiers in the country and all the men who had received a scientific military education were on the side of the Crown. But, on the other hand, there was probably no country in the world where so large a proportion of the common people had a practical acquaintance with the duties of the soldier and so many of its educated men were fitted to change from the duties of peace to those of war. The long contest with the Indians and the French had imbued the people with the military spirit, and familiarized them with the dangers and hardships of war, while to large numbers of the men of ability that contest had been the school in which they had acquired a military education. Washington was a graduate of no military college, but he had acquired the theory and practice of war by years of service alongside of regularly educated British officers, and he was only the most illustrious type of a class. After the conclusion of the Revolution the mass of the people gladly returned to the pursuits of peace, but the military spirit was kept alive partly by tradition and partly by the spectacle of the great wars in Europe going on almost continually during the next generation. The drill and efficiency of the militia was far better preserved than it was a half-century later.

The Constitution of the United States, adopted in 1789, gave Congress the power "To provide for calling forth the militia to execute the laws of the Union, suppress insurrections, and repel invasions." These words conferred upon Congress the power of doing for the Union, as a whole, that which each State in its individual capacity could do for itself. They state briefly but clearly the primary reasons for the existence of a militia. But the Constitution further gave to Congress the power, "To provide for organizing, arming, and disciplining the militia, and for governing such part of them as may be employed in the service of the United States, reserving to the States respectively the appointment of the officers, and the authority of training the militia according to the discipline prescribed by Congress." Further, the Constitution provides that, "The President shall be commander-in-chief of the militia of the several

States when called into the actual service of the United States."

The first act of Congress in regard to "organizing, arming, and disciplining" the militia was passed in 1792; but this, as well as subsequent acts, aimed at little more than to secure a tolerable degree of uniformity among the militia of the different States and a certain amount of agreement with the arming and disciplining of the regular army. In all other important respects the authority of the States was not interfered with.

The war of 1812-14 raised a number of questions as to extent of the power over the State militia conferred upon the general government by the Constitution.

Some maintained that the power conferred on the President to act as commander-in-chief of the State militia when in the actual service of the United States was a power personal to himself and could not be delegated; and as the appointment of officers had been reserved to the States, the militia, even when in the U. S. service, were under no obligations to obey anybody but the State authorities or the President in person. The governor of Vermont went so far as to claim the right to order the militia of that State to return home if, in his discretion, he thought they were more needed at home than in front of the enemy who had invaded a neighboring State. But the decisions of the U. S. Supreme Court and the precedents established by the exigencies of the great civil war of 1861-65 have settled it, probably for all time, that from the moment the militia are mustered into the U. S. service they are, until the expiration of their term of service, as much under the control of the general government, for the purposes which they were called out to aid in accomplishing, as the regular army itself.

The conclusion of the war of 1812-15 and the overthrow of Napoleon Bonaparte were followed, both in America and Europe, by a period of peace extending over a third of a century. The war with Mexico was not a war "to enforce the laws of the Union, to suppress insurrection," nor "to repel invasions," and it consequently afforded the general government no occasion and no opportunity for calling out the militia. No such call was made until the breaking out of the great civil war in 1861. During this long period the interest of the people at large in military affairs and their knowledge of the art of war gradually decayed. The annual meetings for instruction in drill and discipline, the so-called "training days," became mere farces. They were regarded as a sheer waste of time or as something worse, occasions of drunkenness and revelry, profitable only to peddlers and gamblers, and went out of fashion.

When the great civil war broke out each State had upon its statute books an elaborate code of laws in regard to the militia. But by the great body of the people, and especially among the country-people, those laws had long been practically ignored. In most of the large cities one or two militia organizations existed. Some of these, in the accuracy of their drill, the precision of their movements, and the completeness of their appointments, would have compared favorably with the best regiments of any regular army in the world. But such organizations were wholly exceptional.

It was under these circumstances, as regards the condition of the militia, that Pres. Lincoln, on April 15, 1861, issued his first call for 75,000 men for three months' service. The enthusiasm of the people was very great. Had the President called for twice that number they would have been easily obtained. The quotas of the loyal States were quickly filled out. Most of those States, when their quotas were filled, refused to receive any more; other States offered to the general government the services of

far more than they were called upon to furnish. Massachusetts was ready with two and a half times, Rhode Island with four times, Connecticut with three times, Pennsylvania with 60 per cent., and Missouri with three times more than they were asked for. The great majority of the men were intelligent, brave, and eager to do their duty; but it would probably be an exaggeration to say that 10,000 of the 75,000 had any more knowledge of the duties of a soldier than is possessed by every intelligent citizen of full age. But there was something worse than this. The officers were generally as ignorant as the men. It is not possible here, nor is it necessary, to enter into details. The disastrous result of the first battle of Bull Run was necessary in order to convince the people that the attempt to improvise an army, in a few weeks' time, out of men taken from the office, the farm, and the factory, is, in modern warfare, but a waste of treasure and of blood.

The civil war also demonstrated another proposition. If its earlier events proved that untrained troops led by untrained officers, no matter how great their enthusiasm and bravery, were of small account, its subsequent course showed with equal conclusiveness that of all soldiers the well-trained "citizen-soldier" is the most efficient.

The greatest difficulty experienced in the earlier stages of the civil war was the lack of competent officers. Given a regiment in which the commissioned officers all thoroughly understand their duties while all the rest of the regiment consists of men strong and willing, though without knowledge and experience in military affairs, and it can be brought to a high state of discipline and efficiency in a comparatively short time. But where officers as well as men are obliged to learn their business after being mustered into service, the time required increases in an appalling ratio. To educate officers by means of actual service in time of war is a very costly operation. A large number of militia officers during the civil war achieved high distinction, but as a rule they were those who, from natural inclination, had devoted much time, before entering the service, to the study of military science and to practice in organized bodies of militia; or they were men of far more than average abilities, animated by an enthusiasm and determination which no obstacles could oppose.

One of the most remarkable citizen-soldiers, probably in the opinion of professional military men the most remarkable, developed by the civil war was Gen. Alfred H. Terry, who captured Fort Fisher, and at the close of the war was appointed a major-general in the regular army. He entered the service as a colonel, but it would be a great mistake to suppose that he passed, without preparation, from his office to his colonelcy. On the contrary, in his boyhood he had a strong inclination toward everything military. He served in the militia before the war with a kind of serious zeal. From youth to manhood he devoted much of his time to the study of military science. During the Crimean war he visited Europe for the express purpose of seeing military operations on a large scale as conducted in actual warfare. The consequence was that when he led his regiment to the field there was probably no graduate of West Point, no colonel in the regular army, who knew more thoroughly and completely what he ought to do and how it ought to be done.

The experience of our civil war appears to justify the conclusion that, in a free country, the maintenance of a great standing army imposes upon the people a burden at once enormous and unnecessary. With suitable legal provisions and at a comparatively small expense voluntary organizations sufficient both in numbers and discipline can be maintained to meet any sudden emergency and to insure time for prep-

aration for greater crises, provided that certain conditions are fulfilled. The most important of these conditions—indeed, the only indispensable ones—are the cultivation among our youth of a greater interest in military affairs and a greater dissemination of military knowledge among our educated young men. This is not the place to enter upon a discussion of the methods by which these objects are to be attained. The experience of the civil war demonstrated, in the most brilliant and conclusive manner, the thoroughness and completeness of the professional military education imparted by our national school at West Point. But in order to render speedily available, whenever occasion requires, the vast yet dormant and formless military power of our nation, there should be a far larger number of our citizens, than there is at present, who possess a military education somewhere intermediate between the perfection of West Point and that ignorance of the most rudimentary duties of a private and the most elementary principles of military science that characterizes the great mass of our educated young men. Among the measures which might be adopted to accomplish this purpose, the recommendation of Adjutant-General R. C. Drum of the U. S. Army, in his annual report for 1888, that military science should be made a part of the curriculum of our colleges and universities and that all students who are physically qualified should be required to attend lectures, recitations, and drills, is worthy of the most serious consideration.

By the laws of the United States all able-bodied male citizens between the ages of 18 and 45 years, with the exception of such as are exempted by State laws, are bound, when called upon, to do military duty. Thus the liability to render military service extends over 27 years of the citizen's life; but, should peace prevail, not one man in a hundred will ever even play soldier for an hour. The active militia is composed entirely of volunteer organizations. Their discipline must conform to that of the regular U. S. army. Almost everything else is regulated by State laws. The military codes of the different States vary considerably in matters of detail. In certain general features, however, there is substantial agreement. The term of service is generally five years. In order to induce men to enlist in such organizations certain privileges are conferred upon their members both during their term of service and after its expiration. One of the most common of these privileges is exemption from the performance of jury duty. But the State relies chiefly upon the fact that a large number of its citizens believe that they can manifest their devotion to law and order and prove their love of country in no other way so conclusively as by becoming members of some military organization. The State also relies upon the strong desire, which is innate in many men, to participate in military display and to receive their share of the admiration which the general public, male and female, always extends to a handsome, well-drilled military body. In many cases, also, membership of such a body is, to a certain extent, a mark of social distinction. In almost all our large cities there is one, in some of the larger cities more than one, militia regiment of which most young men would be proud to say they were members.

The amount of actual service required by the State in the course of a year does not generally exceed one week; but, of course, any organization which makes any pretensions to military excellence devotes, of its own accord, much more than this amount of time to drill and discipline.

The amount of money appropriated by the State to the support of the militia is very small. Indeed, membership of a militia regiment or company is always a source of individual expense; in some cases,

of very considerable expense. The cities often expend far more than the State upon regiments composed of their own citizens. They do this partly from municipal pride and partly in order that the civil power, in cases of riotous disturbance too extensive for it to cope with, may have at hand a military force upon which it can call for aid in suppressing disorder and maintaining the public peace. In such cases the militia is entirely subordinate to the civil authority. No shot can be fired until the mayor, sheriff, or other authorized civil officer gives permission.

The total number of citizens belonging to militia organizations is limited by law. In proportion to the whole population the number is very small. In the great State of New York, with a population exceeding 6,000,000, the number is limited to 20,000. There is nothing in the whole organization of society in which the contrast between the nations of Europe and the States of the Union is more strikingly illustrated. In Germany, in time of peace, every male citizen not physically incapacitated, is obliged to spend some of the best years of his life in continuous military service. In the United States, in time of peace, only a very small fraction of the citizens are permitted to enter the military service of the State, and then only in such a manner as to hardly constitute an interruption to their ordinary avocations. If any number of citizens beyond the legal limit should desire to form a military organization they can do so in the same manner as they form athletic societies or base-ball clubs, according to their own rules and at their own expense. Such a military club, no matter what it might call itself, and no matter how complete might be its appointments and how perfect its discipline, would no more be a part of the legal military force of the State than the New York Yacht Club is a part of the United States Navy.

According to present regulations officers of the regular U. S. army are detailed to act as professors of military science and tactics in universities, colleges, and schools under prescribed conditions. During the year ending Sept. 30, 1888, forty institutions in different parts of the Union availed themselves of this opportunity of giving instruction in military science, with practice in military drill, to such of their pupils as chose to receive it. The whole number of students over 15 years of age attending these institutions was 7791. Of this number about 4000, or 51 per cent., attended infantry drill. During the previous year the same system had been pursued. The total number of students was less, and only 49 per cent. attended the drills. Should the interest of the students in military matters continue to increase in the same ratio and, above all, should the recommendation of Adjutant-General Drum to make attendance upon the lectures and drills of these officers obligatory upon all students be adopted, it must, in a few years, have a marked influence upon the military efficiency of the militia.

According to the laws of several of the States, the State-militia is required to go into camp for one week in each year. During this time they are supposed to conduct themselves in the same manner as the troops of the regular army would under similar circumstances. Whenever the State authorities request it, officers of the regular army are detailed to inspect these encampments and give instruction to the militia. These officers make minute reports of the results of their observations to the Adjutant-General of the U. S. Army. During the year ending Sept. 30, 1888, such encampments were held in fifteen States. Those desiring the most accurate and authentic information as to the present condition of the State-militia of these fifteen States, including among them the three largest States in the

Union, will find it in the annual reports of the adjutant-general to the secretary of war. "The regularly organized and uniformed active militia of the several States" in the year 1885 aggregated 84,739 men; in 1886 the number was 92,734; in 1887 it had increased to 100,837; and on July 2, 1888, it had an available force of 106,814 men. This is less than one fifth of one per cent. of our population, and less than the whole number of persons subject to military duty when required in the single city of New York.

(W. M. F.)
STATES' RIGHTS. In the general sense, this term, as applied in American political history, contains a reference to the relations subsisting between the United States and the respective States, but it has a special sense that describes a body of opinion that has exercised a large influence in moulding the institutions of this country. It is in this special sense that it is here considered. The States' rights doctrine is a theory of the construction of the Constitution of the United States, and not a general theory of government or communal society. It is to be regarded as an extreme expression of a tendency existing in all communities, definitely exhibited in those that have reached any considerable stage of organization, and especially in those that are composed of organized communities united to form a general or national community, as in the instances of imperial and federal systems of government. This tendency seeks to conserve the individualities of the organic units of the system as against an opposite tendency to blend the entire system into a single homogeneous and consolidated political society by the reduction of the functions of its integral parts, and the enhancement of the powers of the larger system. This tendency has a still broader interpretation, and is found in all organic systems conserving the individualities of their parts and subordinate organs.

The States' rights doctrine, as propounded within ten years after the adoption of the Constitution of the United States, and at a later period made the ground of an attempt on the part of a single State to nullify certain laws of the United States within its territories, and at a still later period the justification for an attempt on the part of several States to secede from the Union, denied to the United States the character of a national sovereign, affirmed that sovereignty remained in the States alone, to whom alone allegiance was due from the citizen; that the powers of the general government constituted an agency created by the States, federating together as independent sovereigns to attain certain definite ends of common interest to them by prescribed and limited means; that the sovereignty of the States remained undiminished by this delegation of powers, and that as such sovereigns they were without a superior to judge of the infractions of the Constitution, and thus entitled to judge, each for itself, of such infractions, and to seek a remedy for such wrongs either in nullifying the acts of Congress thus held to be in excess of its authority, or to secede from the Union and resume a state of entire sovereign independence.

The Constitution had conferred upon Congress the diplomatic and war powers of the government, the maritime police, the regulation of intercourse and the adjustment of differences between the States; certain special powers, including the fixing of commercial standards of value and quantity; general taxing powers, devoted to the payment of the debts, the common defence, and "general welfare" of the United States, and all other powers "necessary and proper" for carrying the same into execution. It was generally conceded that the powers of Congress were limited, but the nature and extent of that limitation were subjects of dispute between those en-

tertaining opposite theories of the proper construction of the Constitution.

An occasion arose, out of the complications incident to the unsettled political condition of France subsequent to the revolution that dethroned the ancient line of her monarchs, for the differences between the two schools of opinion to assume activity. Congress assumed a certain control over aliens and persons engaged in seditious practices within the States, that was claimed by the adherents of the States' rights doctrine to be in excess of its constitutional powers. On the one hand, sympathy with the popular aspirations that produced the French revolution and, on the other, apprehensions for the stability of government in the presence of such uncontrollable forces, gave color and warmth to the discussions that arose, and fitting conditions to produce extreme expressions of opinion on both sides of the question.

The contest was between a strict and a liberal construction of the Constitution. It was claimed by those adhering to a strict construction that the only powers that could be exercised by Congress were those which were specifically enumerated by the Constitution and such incidental powers as were necessary to the exercise of those specifically enumerated; and as authority over the citizens of the States, either permanent or temporary, was not among the enumerated powers, the attempt of Congress to interfere with the authority of the States over their own citizens, on the ground that they were aliens or seditious, was in excess of its constitutional authority. On the other hand, it was contended that the war powers and that of regulating intercourse with foreign nations and between the States justified such action, as essential to the common defence and general welfare. To this it was replied that Congress had no general authority to legislate for the promotion of the general welfare, but was only so far to provide for the general welfare as that was connected with the specific subjects committed to its authority, and that the war powers were inapplicable as the state of war did not then exist. As these differences were irreconcilable, it was necessary to consider whether any constitutional means existed for their adjustment. The national party contended that the national judiciary was the only recourse for their solution under the Constitution. This was denied by the States' rights party, who affirmed that the federal judiciary was the creature of the sovereign States, brought into existence by their act, and could not control its creator. The national party replied that the government of the United States was the supreme authority, superior to the States, within its sphere, and therefore the proper judge of the extent and limits of its authority. As every sovereign government is necessarily the judge of the extent of its authority, subject only to the right of revolution that is inherent in civil society, it was necessary to the position of the party of strict construction that the sovereign character should be denied to the government of the United States, and this position was taken. It was affirmed that the Constitution was the act of the State governments and not of the people of the United States as a whole, and as such was a mere league, of the infractions of which the parties to the compact were the sole judges as well as of the proper means of redress.

The gravity of an issue maintained not only by able and illustrious men but by organized States standing foremost in the rank of civilization, and that presented the alternative of placing the United States in the attitude of a national sovereign clothed with authority adequate to effectuate its purposes at home and to fulfil its engagements abroad, and with rank and dignity equal to that of any other nation, or to reduce it to the level of a diplomatic agency

depending for the effectiveness of its action upon ratification by a numerous body of independent States from whom its authority was derived, renders necessary a statement of the successive steps of this great controversy.

The war with Great Britain to maintain the declaration of independence made by the colonies exhibited the necessity of concerted action on their part and led to their confederation and representation in the Continental Congress. In this body each State, through its delegates, had an equal voice with each other in the adoption of public measures; but such measures lacked effectiveness through the frequent failures of the States to comply with the demands made upon them, and the inability of Congress to coerce compliance therewith. A profound conviction of the necessity of enlarging the powers of Congress arose throughout all parts of the country, that continued to gain strength after the conclusion of the war, and finally led to the calling of the convention of 1787, in which the present Constitution, apart from the amendments subsequently made, was passed for submission to the people of the United States.

The earliest plan submitted to the convention was that of Mr. Edmund Randolph, of Virginia. This plan proposed a national government, both in name and in substance. The essential feature was that it was to be derived directly from the people and was to act upon the people through laws judicially expounded and enforced by the national government. The powers of the government were respectively described as the national executive, the national legislature, and the national judiciary. The jurisdiction of the national government was to be confined to certain subjects, but in the exercise of its powers over these subjects it was to act as a sovereign government, superior to the governments of the States. The powers that were withheld from the general government were to be retained by the States, to be exercised by them as sovereign governing communities. According to this plan the political governments of the United States and of the respective States were to act independently of each other, but the national government, being supreme, its laws, properly enacted, would operate directly upon the people in such manner as to deny validity to any law of a State that infringed upon the national powers.

The Virginia plan was supported by the larger States, of which Virginia, Massachusetts, and Pennsylvania were the largest, both as to territory and population. The advantage of this plan to the large States was that, as the system was based upon popular majorities, they would have the greatest advantage from it, as a consequence of their being the most populous.

The smaller States, especially New Jersey, Delaware, and Maryland, were opposed to the Virginia plan, as giving a preponderating influence to the large States in the proposed government. They preferred the plan of the then existing confederacy, in which each State had an equal voice with every other in public affairs.

Mr. Patterson, of New Jersey, submitted a plan that received the support of the smaller States. This plan was based on the federal idea, according to which a federal government was to be instituted under the authority of the governments of the respective States, in which each State should have an equal voice with every other. According to this plan the federal government could only carry out its purposes through the aid of the State governments, having no efficient means of its own for the purpose. As the federal government could only act through the States, it was necessary to its existence that it should possess the means of coercing a State that

should fail to discharge its proper duties, and such a provision was contained in the plan.

A third plan was offered by Alexander Hamilton, of New York, which proposed a national government of unlimited powers, but which was not brought into discussion by the convention. South Carolina, throughout the discussions of the convention, adhered to the views of the larger States, and upheld the plan of a national government with limited powers.

Although a conflict of interests was recognized in the course of the discussion as existing between the Northern and Southern States, arising from the diversification of their respective institutions and industries, especially in view of the assumed necessity of perpetuating the institution of slavery in the last-named States, yet that consideration led only to modifications of details, and had no apparent effect upon the fundamental principle of the proposed government, the controlling influence in that respect arising from the political interests connected with the unequal distribution of population among the States.

These differences between the larger and the smaller States were adjusted, principally, in the constitution of the national legislature. The House of Representatives was to be chosen directly by the people of the States, who were to be represented in the ratio of population, so that a majority of the House would represent a majority of the people of the United States, without regard to State lines. By this disposition the people of the United States were unified as a whole for the purpose of making laws that should operate upon themselves, collectively and individually. Such governmental authority, so derived, where responsible to no higher authority, was necessarily sovereign, and where the objects for which it is created are national, as involving interests common to an entire independent community, such sovereignty is necessarily of the sovereign type.

The smaller States, while yielding thus far to this national scheme, insisted that the States in their political capacities should have a negative upon the popular action of the House of Representatives by giving to each State, independent of the extent of territory or population, an equal voice in the Senate, or what was then called the second branch of the national legislature. The larger States at length yielded to this demand, and it was concluded that each State should be represented by two senators, chosen by the legislatures of the respective States, constituting a senate which should have a negative upon all action of the popular branch, as well as upon certain functions of the executive that concerned treaties and appointments to office.

What was intended by the arrangement of the national legislature was that in all matters the action of the government of the United States should conform, on the one hand, to the will of the majority of the people of the United States as a whole, and, on the other hand, to the desires of a majority of the States as separate political bodies. Both of the schemes of government thus embodied in the Constitution contemplated a controlling influence of the general government over the States in all matters of national concern, the one that embodied the federal idea propounding direct coercion for that purpose, while the national plan secured the same end without coercion applied to the political government of the States by having direct authority over the people of the States by which they might be compelled to conform to the laws of the United States, and be prevented from conforming to the laws of the States that were infractions of the national right.

In the final framing of the Constitution the terms "national" and "federal" were both dropped without

eliciting any discussion tending to show that any important interests were regarded as in any way connected with their use or omission, and that the change was formal merely, such as might have been induced by the consideration that descriptive words were not necessary to define the nature of a government whose jurisdiction and powers had been fully set forth in its constitution.

It has been claimed in public discussion that the plan of a national government was rejected by the convention as inconsistent with the proper independence of the States, but this is obviously an error. Mr. Madison, whose report of the proceedings of the convention is accepted as standard authority, was in later years an advocate of the doctrine of States' rights, and it is not to be assumed that he either intentionally or accidentally suppressed so important a feature of the discussion. The discussions and action of the convention show that no other idea than that of a national government was entertained; that the subjection of the people of the States to the authority of the general government in all matters committed to that government was fully intended to be direct, so that the necessity of coercing the political governments of the States could never arise. Such a direct governmental relation between the general government and the people of the States constitutes the authority exercisable through it as sovereign, and that implies power to determine its own limits of authority, subject only to the ultimate right of popular revolution.

The differences between those who adhered to a strict and those who advocated a liberal construction of the Constitution were brought into discussion in the first Congress, in 1791, on the occasion of the incorporation by Congress of the Bank of the United States. Mr. Madison opposed the measure as beyond the competency of Congress. It was claimed by the advocates of the measure that such a financial institution was a necessary and proper means of enabling the government to exercise the functions conferred upon Congress by the Constitution. The position assumed by Mr. Madison was that a case of strict necessity must appear, to warrant the exercise of the power as within the class of incidental powers, and that it was not sufficient to justify its exercise that the facilities afforded by such an institution would be a convenience to the administration of the government. His view was that nothing was to be added by implication to the specific powers conferred upon Congress unless such implication arose out of actual necessity incident to the exercise of such specific powers, and that the fitness of the means proposed to attain its end was not the test of the propriety of the implication, but the circumstance that without such means the power could not be properly exercised. The charter of the bank was granted by Congress, and the institution was in operation many years before the discussion as to the validity of the authority under which its powers were exercised again attracted general attention.

In 1792 Mr. Madison opposed the granting by Congress of bounties to promote the cod fisheries upon the ground that it was not within the power of Congress. It had been contended that the authority of Congress to provide for the general welfare justified the exercise of the power claimed. Mr. Madison held that the authority of Congress to provide for the general welfare was limited to cases in which the general welfare was involved in some question relating to the specific subjects committed to the jurisdiction of that body. The discussion of this construction was renewed at a later day under circumstances giving it a wider and more interesting range, that will be mentioned.

The passage by Congress of the laws known as the Alien and Sedition laws was the first of a series of

important public events that brought into general discussion the nature and extent of the powers of Congress, and the means possessed by the States for confining the government of the United States within its legitimate sphere and restraining it from encroachments upon the reserved rights of the States, the succeeding events being the attempted nullification by South Carolina in 1832 of certain revenue laws, and the attempted secession from the Union of certain States in 1861.

The popular sympathy which in this country was ardently excited during the early stages of the French revolution in behalf of the condition and aspirations of our late ally gave place to apprehension for the safety of our own institutions and our amicable relations to foreign powers, as the instability of popular institutions in France was made apparent. Danger was apprehended from intrigues engaged in by resident aliens, and Congress authorized the President to remove from the United States aliens found here, upon such evidence of public danger arising from their presence as might be satisfactory to his own mind. At the same time a law was passed by Congress to punish sedition committed or attempted in the United States and the publication of statements and opinions hostile to the action of the government.

The warmth of discussion that followed the enactment of these laws was not alone due to the fact that to many it seemed that Congress had designedly overstepped the limits of its authority, and had entered upon a scheme of consolidating the national power by the destruction of the liberties of the States, but was due in part to the approaching political crisis that transferred public authority from the hands of the Federalists to those who, under the name of Republicans, were to control its destinies for many years, and also in part to the belief of many that the laws in question overthrew certain barriers indispensable for the protection of individual liberty, such as the right of trial by jury, the freedom of speech, of the press, and of religion.

The legislature of Kentucky in 1798 passed certain resolutions, of which the first, containing the statement of principles on which they were based, was as follows:

"1. *Resolved*, That the several States composing the United States of America are not united on the principle of unlimited submission to their general government; but that, by compact, under the style and title of a constitution for the United States, and of amendments thereto, they constituted a general government for special purposes, delegated to that government certain definite powers, reserving, each State to itself, the residuary mass of right to their own self-government; and that whensoever the general government assumes undelegated powers, its acts are unauthorized, void, and of no force; that to this compact each State acceded as a State, and is an integral party; that this government, created by this compact, was not the exclusive or final judge of the extent of the powers delegated to itself, since that would have made its discretion, and not the constitution, the measure of its powers; but that, as in all other cases of compact among parties, having no common judge, each party has an equal right to judge for itself as well of infractions as of the mode and manner of redress."

The remaining resolutions of the series declare certain acts of Congress, including the alien and sedition laws, to be in excess of the authority of Congress and void, as highly dangerous to the liberties of the States and the people, that immediate redress was demanded, and provide for the transmission of the resolutions to Congress and to the other States.

It is noticeable that these resolutions indicate no mode of redress, although claiming that each State had

the independent right to judge of the infractions and of the mode of redress, and propose no second course of action to be pursued by that State, either alone or concurrently with any other States. They were evidently intended as a declaration of principles for the consideration of Congress and of the people at the approaching general elections, looking to the repeal of the obnoxious laws and the overthrow of the party conducting the government.

The value of these resolutions as a statement of the doctrine of States' rights depends upon certain propositions advanced, and the reasons assigned for their verity. The leading statement is to the effect that the general government, "was not made the exclusive or final judge of the extent of the powers delegated to itself," and the reason assigned is that that would make its discretion the measure of its powers. Dependent upon this proposition, and necessarily true if the preceding one is established, is the proposition that each State has the right to judge for itself as well of infractions as of the mode and manner of redress.

The reason assigned for this statement is that it is a consequence common to all other cases of compacts among parties having no common judge. This compact is described as one made by the States for certain definite purposes. The denial of the existence of any common judge negatives the attribute of sovereignty in the United States, as all sovereign governments are superior to all the individuals and communities constituting them, and are judges of the limits of their powers. It is obvious, then, that the Constitution was regarded as a league among sovereign States creating certain governmental agencies, but parting with no part of their sovereignty. If such be the case, the principle that each party must judge for himself of the infractions and mode of redress would be applicable, assuming the non-existence of any competent judge among them.

The resolutions of the Kentucky legislature were sent to the several States then composing the Union, and replies were returned by several of these States, all of which, except that of Virginia, denied both the principles of construction applied by Kentucky to the Constitution and her deductions from those principles. Upon the receipt of these replies the legislature of Kentucky, in 1799, passed additional resolutions reiterating the positions assumed in the resolutions of the preceding year, and declaring "that the several States who formed that instrument, being sovereign and independent, have the unquestionable right to judge of its infractions; and that a nullification by those sovereignties of all unauthorized acts done under color of that instrument is the rightful remedy." At the conclusion of the resolutions they declare their object to be a solemn protest. As in the first series of resolutions, no purpose on the part of the State in view of the conditions stated is disclosed, and a disinclination to present an ultimatum is evinced by the emphatic statement of the object of the resolutions as that of a protest.

In view of the declination of a majority of the States of the Union to sanction the ground assumed by Kentucky, the only course open to that State was either to abandon its position or to claim that it was the right of individual States to seek such redress as to them respectively might seem appropriate, and this last of the alternatives was acted upon by the resolutions of 1799.

Following the resolutions of Kentucky, and in the same year, 1798, the legislature of Virginia passed resolutions upon the same subject, that were proposed by Mr. Madison. This action is in form and substance a protest addressed to the several States of the Union against the Alien and Sedition laws enacted by Congress. Adhesion to the Constitution and firm attachment to the Union are de-

clared. It is announced, "That this Assembly doth explicitly and peremptorily declare, that it views the powers of the federal government as resulting from the compact to which the States are parties, as limited by the plain sense and intention of the instrument constituting that compact, as no farther valid than they are authorized by the grants enumerated in that compact; and that in case of a deliberate, palpable, and dangerous exercise of other powers, not granted by the said compact, the States, who are parties thereto, have the right, and are in duty bound, to interpose, for arresting the progress of the evil, and for maintaining, within their respective limits, the authorities, rights, and liberties, appertaining to them." Regret is expressed that Congress appears disposed to assume unconstitutional powers tending to a consolidated government. Protest is made against the Alien and Sedition laws as the exercise of a power not delegated, that violates fundamental principles of liberty of conscience and the press. An appeal is made to the people of the States to "concur with this commonwealth in declaring, as it does hereby declare, that the acts aforesaid are unconstitutional; and that the necessary and proper measures will be taken by each for co-operating with this State, in maintaining unimpaired the authorities, rights, and liberties, reserved to the states respectively or to the people." Direction is given that copies be sent to the legislatures of the several States.

The Virginia resolutions of 1798 advance no opinion as to the existence of a constitutional remedy for the grievances complained of, indicate no line of action that ought to be pursued by the State beyond that of consultation with the sister States, and propose such consultation as the only object beyond that of entering a protest against the action of Congress. The case stated as imposing upon the States the duty of arresting the progress of the evil, and maintaining their liberties, is that of "a deliberate, palpable, and dangerous exercise of other powers not granted by the said compact." As a solemn public protest in a great national exigency, its words must be taken with that limitation suggested by the gravity of the occasion. The powers thus seized upon by Congress must be dangerous in their character, as where they violate fundamental principles of liberty, especially the liberty of conscience and the press, as charged against the action of Congress in another part of the instrument. Such powers must be obviously and unquestionably improper for Congress to assume, in order to satisfy the expression, "palpable." Finally, they must have been assumed for some purpose hostile to the objects of the Constitution, as for the purpose of establishing a consolidated government, as elsewhere charged in the same instrument, in order to satisfy the expression, "deliberate." If the case as stated had been actual, the right of revolution would have undoubtedly given the appropriate remedy, and the mode in which Virginia dealt with the question, if she so believed, must be regarded as moderate and conservative.

These resolutions were transmitted to the other States and replies were received from Delaware, Rhode Island, Massachusetts, New York, Connecticut, New Hampshire, and Vermont, all dissenting from the position of Virginia, and the majority of them claiming that the questions involved were proper for consideration only by the judiciary of the United States.

The character of the replies received and criticisms that had been made, unfavorable to the action of Virginia, induced the legislature of that State to reconsider the whole subject, and a report was made to that body by Mr. Madison reviewing the entire subject.

The report of Mr. Madison, made and adopted in the year 1800, sustains the propriety of the resolutions of 1798. It discusses the constitutionality of the Alien and Sedition laws, the character of those laws as violating fixed principles of government, and the propriety of the measures proposed by the resolutions of 1798.

The question of constitutionality is considered mainly under the clause of the Constitution that enables Congress to provide for the public defence and general welfare of the United States. He regards the authority to provide for the general welfare as limited to the specific objects enumerated as the powers of Congress. He contends that the only other construction possible would be that which should claim that anything that might tend to promote the welfare of the States as a whole might be done by Congress under it; that this would render nugatory the limitations intended to be imposed by the enumeration of specific powers. The report defends the resolutions from the charge of recommending improper measures, contending that all they intend is to bring about discussion and comparison of ideas among the States, whose action may be confined to representations to Congress to induce the repeal of these laws. It is claimed that the States have the right under the Constitution to confer together and concert action proper to be taken under the Constitution. The action of the legislature upon this report did not change the position of affairs assumed by the resolutions of 1798, either as to their form or effect.

The effect of the clause of the Constitution that enables Congress to provide for the general welfare has always had a conspicuous place in the discussions of the advocates of the different schools. This discussion has a prominent place in the report of Mr. Madison, as a vital feature of the controversy. If that clause was to be taken in its broadest sense, the power of Congress would seem to be unlimited, for it would, in that case, stand as a grant of general legislative power in the broadest terms. It was always conceded by those who put the most liberal construction on the Constitution that the powers of Congress were subject to limitation, and this excludes the clause under consideration from receiving the broadest construction of which it was capable if standing alone. The narrower doctrine was that Congress could only provide for the general welfare where matters were involved that were of common interest to the whole Union, which would place beyond the authority of Congress the attainment of objects of merely local interest. This construction Mr. Madison rejects and propounds the very stringent doctrine that Congress can only consider and provide for the general welfare as it regards the subjects placed in the enumeration of its powers. Intermediate between the larger construction, which Mr. Madison rejects, and the narrow one propounded by him is another, that does not appear to have received attention in the discussions at that time. In addition to the powers conferred upon Congress, certain other powers are inhibited to the States; if, then, a power thus inhibited to the States is of such a nature that its exercise is essential to the maintenance of government, the question whether the authority to provide for the general welfare did not authorize such power to be exercised by Congress, as a necessity of government, is one that would have to be considered before the rule of construction propounded by Mr. Madison could be accepted as a finality.

The agitation excited by the Alien and Sedition laws, that at one time threatened the stability of the Union, passed into the arena of general politics, and was one of the causes that placed Mr. Jefferson in the presidency, producing, through a change of

the persons administering the government, a change in its policy rather than of its nature. The prevailing tendency of popular excitements to find expression in the elective act, a striking feature and safeguard of our institutions, had its first distinct development in the instance of the Alien and Sedition laws, and is readily accounted for when it is observed that the road to the acquisition of public authority is made easy through popular ferment, and that the temptations to acquire such authority are greater than those that lead in the direction of dismembering and crippling the government.

In 1811 the question of the repeal of the charter of the United States Bank was agitated in Congress, and Mr. Clay opposed the power of Congress to incorporate a bank. He says: "What is the nature of this government? It is emphatically federal; vested with an aggregate of specified powers for governmental purposes, conceded by existing sovereignties, who have themselves retained what is not so conceded. It is said that there are cases in which it must act on implied powers. This is not controverted; but the implication must be necessary, and obviously flow from the enumerated powers with which it is allied. The power to charter companies is not specified in the grant, and, I contend, it is of a nature not transferable by mere implication. It is one of the most exalted attributes of sovereignty."

In the foregoing statement Mr. Clay should be regarded as conceding that sovereignty resides in the United States, as its powers are described as governmental, though limited, and emanating from a sovereign source; as the quality of that retained by the States is sovereign, that which they parted with, being intended for the same general uses, must have the same nature. He employs the term federal in the sense that has become general, as implying a governmental relation between communities exercising sovereign authority united through a common law for governmental purposes. Conceding the sovereignty of the United States, the right to judge of the limits of its powers, depending on the fact that such sovereignty is supreme, must be regarded as conceded, and hence Mr. Clay could not but regard the question of the sufficiency of the grounds of implying powers in the government of the United States as proper for decision by its judiciary.

In 1816 the Supreme Court of the United States, in the celebrated case of *Martin vs. Hunter*, was called upon to place a construction upon the Constitution as to the nature and limits of the powers of Congress. The judiciary act had provided for appeals from the highest courts of the States to the Supreme Court of the United States where questions of a federal nature were involved in their decisions.

This feature of the law was strenuously resisted as an assumption of authority not granted by the Constitution. Judge Story, delivering the opinion of the court, claimed that the Constitution proceeded from the people of the United States, and not from the States as political bodies, and that it was intended to limit the sovereignties of the States, and render the United States supreme, within its proper jurisdiction, over all State authority. His conclusion was, and such was the judgment of the court, that the grant of jurisdiction over cases arising under the Constitution, laws, and treaties of the United States is absolute, and, as such, extends to an appellate jurisdiction over the judgments of the State courts where questions of that nature arise.

The Supreme Court was again, in 1819, called upon to examine the fundamental nature of the powers exercised by Congress. The State of Maryland had assumed to impose a tax upon the operations of a branch of the Bank of the United States located in that State, and a controversy arose and was brought into that court involving the constitu-

tionality of the authority under which the bank exercised its powers, and of the act of Maryland taxing the institution. The court affirmed the authority of Congress to create the bank, and denied that claimed by Maryland. The position assumed by the court, as stated in the opinion of Chief Justice Marshall, is substantially as follows: The government of the United States was created by the people of the States as a sovereign government, though its jurisdiction was limited to certain specified subjects; that in relation to such subjects it was sovereign and superior to the States; that, in addition to the enumerated powers, it was intended to have all such powers as were proper in order to carry into execution the enumerated powers; that in the choice of means to carry out its powers it was not limited to such as were indispensably necessary for that purpose, but could use such as in its judgment were reasonably necessary and proper for that purpose; that it was the sole judge of the propriety of the means adopted so long as those means were suitable to the nature of the powers enumerated; that the power to borrow money and levy taxes implied the creation of banks to that end; that a law of the State of Maryland subjecting the powers granted to the bank to restrictions was inconsistent with the sovereign authority of Congress over the subject, and was therefore unconstitutional and void.

In 1828 Congress enacted a law imposing duties upon foreign importations, which was claimed to be intended for the protection of domestic manufactures, that gave rise to animated discussion both in Congress and in the States. In 1830 this discussion was maintained by Mr. Webster and Mr. Hayne, of South Carolina, in the celebrated debate upon the powers of the government. Mr. Webster's position was that, apart from the right of revolution, there was no power in any State to resist the authority of Congress under the Constitution. That the government of the United States was established by the people, and its responsibility is to the people alone. He admitted that New England had opposed the embargo law on the same grounds that South Carolina opposed the tariff, but had submitted to an unwelcome decision against her claims. He regards the Virginia resolutions as indefinite as to whether revolutionary or constitutional means of redress were intended. He says: "I hold it to be a popular government, erected by the people; those who administer it responsible to the people, and itself capable of being amended and modified just as the people may choose it should be. It is as popular, just as truly emanating from the people, as the State governments. It is created for one purpose, the State governments for another. It has its own powers, they have theirs. There is no more authority with them to arrest the operation of a law of the Congress than with Congress to arrest the operation of their laws."

Mr. Hayne in reply claimed that the government of the United States emanated from the sovereignties of the States as organized governments, and hence the agencies created could not control the power by which they were created. He regards the action of a State declaring the action of Congress as unconstitutional as a check which ought to be respected until appeal is made to the States collectively to ascertain their will in the matter, thus excluding the idea of coercion of a State on the part of Congress.

Mr. Webster, replying to Mr. Hayne, took the ground that, assuming the position that the Constitution emanated from the State governments, still the claim of South Carolina that a single State has an independent right of construing it cannot be maintained, as it could only be construed by the States acting together. And even in that case, where a means of deciding questions of construction was designated by the contracting parties, that means of

decision would be competent, and the only competent means. But he disputes this assumption, and contends that the people of the States, in their collective capacity as the people of the United States, made the Constitution.

In 1832 the first attempt was made to put into practical exercise the doctrine that the Constitution was a mere league or compact between sovereign states by which they parted with no part of their sovereign authority, but merely created certain governmental agencies for the common benefit, and subject to their control. In that year South Carolina adopted, in convention, an ordinance that declared unconstitutional and void the acts of Congress alleged to have been passed for the purpose of protecting domestic manufactures, and assumed to nullify those acts within the territories of that State, and threatened that if an attempt was made to apply force to the State she would withdraw from the Union and establish a separate government. The history of these transactions is given in another place under NULLIFICATION.

Assuming the premises claimed by South Carolina, that the Constitution created no sovereign authority that could be asserted as superior to the States, and that could act as the judge of the extent of the obligations assumed by the States, it would be difficult to deny the right of each State to act for itself in the manner propounded by the Kentucky resolutions, and practically acted upon by South Carolina in 1832.

The difficulty lies in maintaining the assumption that was the foundation of the deductions upon which that State sought to act. In addition to Congress and the judicial authority conferred upon the courts of the United States, a supreme arbitrator was created by the Constitution superior to the Constitution itself, and competent to bind the States by obligations that had not been assumed with the Constitution. The power of amendment over that instrument was placed in the hands of three-fourths of the States, and its exercise was to be binding upon the remaining States. This power of amendment was only limited in two respects, one of which related to control over the migration and importation of persons, and the other to the distribution of direct taxes. Beyond this limitation the power of amendment was unlimited. To affirm that a power by which a majority of a collective community of individuals or states may control the entire community, in an almost unrestricted manner, does not import sovereign authority, is the chief difficulty in the argument in favor of separate State liberty. A contract by which the majority of the contracting parties may change the terms of contract is certainly not an ordinary contract, and very clearly implies the existence of governmental authority that is inseparable from the idea of sovereignty. It is equally difficult for a State to say that it has only parted with so much of its liberty as is embodied in the terms of a certain instrument, where it has lodged in the hands of a power that may act independently of its authority ability to change those terms, and thus to subject it to new obligations. Nor is it easy to conceive by what reasoning it can be maintained that a supreme power that may mould the obligations of States can exist independently of the possession of power to judge of infractions of its requirements.

The attitude of South Carolina called forth the celebrated proclamation of Pres. Jackson that vindicated the national sovereignty of the United States, and the supremacy of her judiciary over all controversies arising out of the terms of the Constitution.

South Carolina at length yielded to a compromise act proposed by Mr. Clay by which the principle of national imposts for the protection of domestic manufactures was retained but certain economic advan-

tages were secured to South Carolina, according to her estimation, by the gradual reduction of the duties imposed to a minimum to be reached by 1842.

The next and final effort to practicalize the ideas of State liberty propounded by the States' rights doctrine was in 1860 and 1861, when South Carolina passed an ordinance for the secession of that State from the Union, and was followed by ten of the States that adhered to the system of legal slavery. The election of Mr. Lincoln to the presidency in 1860 was the transfer of public authority from the southern group of States to the section of the Union where slavery had become extinct, and was interpreted by the seceding States as an indication that that system could not look to indefinite continuance. The history of the events attending this effort to withdraw from the Union is given in another place under SECESSION. Armed resistance to the authority of the United States commenced with South Carolina, and a state of active hostilities ensued. The seceding States formed a confederated government and demanded that they should be treated as belligerents according to the laws of war, and this concession was made. The issue of the conflict was determined by military means, and the final surrender of the armies of the confederacy subjected the territory of those States to the consequences flowing from a state of war, according to which the supreme authority remained in the hands of the conqueror to be exercised according to his will. After a brief interregnum of military government, Congress provided for the readmission of the seceded States into the Union, establishing by its authority the popular basis upon which such reconstruction should take place. The people of the several States that had yielded to the military power of the United States accepted the conditions offered by Congress and formed State constitutions and governments, and were readmitted to representation in Congress. The history of these events is given under RECONSTRUCTION.

The whole force of the States' rights doctrine was centred in the question of the right of one or more States to secede from the Union where they had adjudged the action of Congress unconstitutional and detrimental to the liberties of the States. Nullification could only be regarded as a temporary remedy mainly intended, as claimed by Mr. Hayne, as a check to induce more full consideration before acting upon doubtful powers. The same argument that would sanction the right to nullify the laws of the United States within a State would justify that State to secede from the Union if the act of nullification proved insufficient as means of redress.

The entire question must then be regarded as involved in the related attitudes of the United States and the confederated States. That the States that remained in the Union after the act of secession held to the opinion that such right of secession did not exist is evidenced by the fact that they based the right to make war upon it. With the success of their arms restoration to the statehood implied acceptance of the principles of which the war was the expression. The doctrine of the war was the indissoluble union of the States, to form a sovereign national government, and the restoration of the States to full constitutional rights was the acceptance of a corresponding obligation upon the States thus restored. The consequence of this acceptance was that the judiciary of the Union, the people of the United States, and the States in the exercise of constitutional powers, were the ultimate recourse for the solution of all questions of right and duty on the part of States or individuals within the Union. (A. J. W.)

STAUNTON, a city in Virginia, county seat of Augusta Co., is in the Shenandoah valley, on Lewis Creek, 60 miles N. of Lynchburg. It is on a branch

of the Baltimore and Ohio Railroad. It has a courthouse, 2 banks, 10 churches, a high school and excellent private schools, the State asylum for lunatics, and the State institution for the blind, deaf, and dumb. It contains also large iron-works, flour and planing mills. Three weekly newspapers are published here. The population in 1880 was 6664.

STEDMAN, EDMUND CLARENCE, poet and critic, was born at Hartford, Conn., Oct. 8, 1833. He entered Yale College in 1849, but left after some breach of discipline, though the degree of A. M. was conferred on him in 1871. While yet in college his poem *Westminster Abbey* won a prize, and appeared in the *Yale Literary Magazine* in 1851. After editing the *Norwich Tribune*, 1852-53, and the *Winsted Herald*, 1854-56, he removed to New York, and wrote for the magazines and newspapers. His first notable success was gained in 1859, through the appearance in the *New York Tribune* of *The Diamond Wedding* and several other pieces in verse. These, with others, were gathered in his *Poems, Lyric and Idyllic* (1860). *The Prince's Ball*, reprinted from *Vanity Fair* later in the same year, commemorated the visit of the Prince of Wales to the United States. In 1861-63 he was war correspondent of the *World*, writing from headquarters of the Army of the Potomac, and from Washington. Returning to New York in 1864 he gave up journalism for the stock exchange, but continued to write verse. His *Alice of Monmouth* appeared, 1864; *The Blameless Prince, and Other Poems*, 1869; *Rip Van Winkle*, 1870; and subsequent volumes, 1877 and 1879. His *Poetical Works* were collected in 1873, and in a *Household Edition* in 1884. Some of his poems were written for special occasions. *Gettysburg* was read before the Army of the Potomac at Cleveland in 1871, an *Ode* at Dartmouth College in 1873, *The Monument of Greeley* at the dedication in Greenwood Cemetery in 1876, *The Death of Bryant* before the Century Club in 1878, *Meridian* at the 25th anniversary of his Yale class in 1878, and *Corda Concordia* before the Concord School of Philosophy in 1881. Of late years Mr. Stedman has turned his attention to criticism, and done some of the best-considered critical writing that has been produced in America. Articles in *Scribner's*, afterward *The Century*, were the basis of his *Victorian Poets* (1875), of which the 13th edition (1887) is brought down to date. His *Poets of America* (1886) is a similar work, deserving even greater praise, on account of his steadfast maintenance of the true judicial tone. Mr. Stedman edited Austin Dobson's *Poems* (1880), and, with T. B. Aldrich, *Cameos* from Landor (1874). He is now, with Miss Ellen M. Hutchinson, editing a *Library of American Literature*, being selections from all home writers of any note from the earliest colonial times: this is to fill ten large volumes.

STEEDMAN, CHARLES, rear-admiral, was born, Sept. 24, 1811, at Charleston, S. C. In 1828 he entered the navy as midshipman; in 1834 became passed midshipman, cruising in the frigates *Constitution* and *United States*. In 1841 he received his promotion as lieutenant, and in 1846-47 served in the Mexican war in the sloop *St. Mary's*. When Vera Cruz was bombarded he had command of the siege-guns in the naval battery on shore, and, besides other operations on the coast, took part in the boat-expedition that effected the capture of Tampico. In September, 1855, he was promoted to commander, and as such was in charge of the brig *Dolphin* in the Paraguay expedition. When his native State seceded in 1861 he resisted the efforts of family and friends and remained loyal to the Union, to which he rendered efficient service. His first service in the cause was to convey Gen. Ben. F. Butler, with the Eighth Massachusetts Regiment, from Havre de Grace to Annapolis, Md., in the railroad ferry-steamer *Maryland*, the command of which he received in an-

swer to his request for duty. Thereafter he served under Admiral Foote in the organization of the naval force that manned the gun-boats on the Mississippi. In September, 1861, he co-operated, as commander of the steamer *Bienville*, in the capture of Port Royal, and in the operations on the coast of Florida and Georgia. In September, 1862, he was made captain and, in charge of the Powhattan, took part in the blockade of Charleston, in various engagements there, and in the capture of Fort McAllister, on the Ogeechee, which led to the evacuation of Savannah. After towing the captured ram *Atlanta* to Philadelphia, he went in command of the *Ticonderoga* to the coast of Brazil in pursuit of the Confederate cruiser *Florida*. In this vessel he continued to serve during the remainder of the war, taking part in several operations, and finally went on a cruise in the Mediterranean, whence he returned in 1867, in command of the frigate *Colorado*. Meantime, in July, 1866, he had been appointed commodore. From 1869 to 1872 he was in charge of the Boston navy-yard. In May, 1871, he was advanced to rear-admiral, and finally retired from the service, Sept. 24, 1873.

STEEDMAN, JAMES BARRETT, general, was born, July 30, 1818, in Northumberland Co., Pa. He was emphatically a man of energy and action, and before the war had been a contractor on the Wabash and Erie Canal, a member of the legislature of Ohio, the organizer of a party to cross the plains to California in search of gold (from which he returned next year), a member of the Ohio board of public works, the public printer at Washington during Buchanan's administration, and a delegate to the convention at Charleston in 1860, where he advocated the nomination of Stephen A. Douglas. On the outbreak of the war he became colonel of the Fourth Ohio Regiment, and was sent to Western Virginia. Here he was engaged in the battle of Philippi; thereafter he joined Gen. Buell in Kentucky, and in July, 1862, was promoted to brigadier-general. In this capacity he rendered efficient service at the battle of Perryville, arriving on the field just in time to drive back the enemy, who had broken the Union line. In July, 1863, he was appointed to the command of the First division of the reserve corps of the Army of the Cumberland, and at the battle of Chickamanga re-enforced Gen. Thomas at a moment of great emergency. For this he has been given the credit of saving the day, though the honor of suggesting the movement is usually assigned to Gen. G. Granger. His services here earned him the rank of major-general (April 24, 1864). He afterward served in Sherman's Atlanta campaign, everywhere showing zeal and courage. When Thomas left the expedition to return to Nashville, Gen. Steedman joined him, and performed efficient service. In 1866, after serving as provisional governor of Georgia, he resigned, and received the appointment of collector of internal revenue at New Orleans. Here his want of familiarity with business involved him in financial difficulties, and he returned to Ohio. In 1879 he was elected to the State senate, but on a second canvass was defeated. A few months before his death he was made chief of police of Toledo, where he was ostensible owner and editor of the *Weekly Ohio Democrat*. He died at Toledo, Oct. 18, 1883.

STEEL. Every description of iron ore will give cast iron and wrought iron, the properties of the product obtained depending upon the ore and the method used; but in all cases the terms "cast iron" and "wrought iron" will be applied to the extreme results and all intermediate products which cannot be classed with cast iron on the one hand, or the wrought iron on the other, may be called steel. It forms the link between cast and wrought iron, and unites the properties of both, the distinguishing

characteristic being that it may be hardened or softened at will by rapid or slow cooling. When exposed to heat it takes on in succession the following colors:

1. A faint yellow, which shows the proper temperature for lancets and other fine cutters that require the finest edge, with but little strength of metal.
2. A pale straw-yellow, the temperature for razors and surgical instruments.
3. Full yellow, for pen-knives, with increased toughness.
4. Brown, with purple spots, for axes and carpenters' tools.
5. Bright blue, for swords and watch-springs.
6. Full blue, for fine saws and daggers.
7. Dark blue, for large saws, or instruments that may be sharpened with a file.

Proportions of Carbon in Steel and Iron.

	Percent. of carbon.
Pure wrought iron.....	0.000
Soft steel.....	0.075
Mild steel.....	0.08 to 0.20
Hard steel.....	0.20 to 0.40
Tool steel.....	0.40 to 0.80
Malleable cast iron.....	0.88 to 1.58
Draw-plate steel.....	3.80
Cast iron.....	4 to 5

Steel, then, may be produced by any process which adds carbon to wrought iron or reduces it in cast iron.

Puddled steel is made in the puddling furnace. In changing into wrought iron in the furnace the metal passes through the state of steel, or becomes steel before it becomes wrought iron; so to get steel the usual puddling process is stopped at such a stage in the working as will give steel.

A very old process is the process by cementation or heating bars of iron embedded in charcoal for from six to ten days. The iron is in the form of straight bars about 3 inches wide and $\frac{1}{2}$ inch thick. Fine charcoal in cubes of $\frac{1}{4}$ to $\frac{1}{2}$ inch edge is placed in the bottom of the converting pot or chest, which is made of fire-brick or fire-stone; on this the bars are laid close together, and then another layer of charcoal about $\frac{1}{4}$ inch thick and a layer of bars, and so on till the chest is full, when a thick layer of charcoal is placed on the top and a compact, air-tight covering of grinder's waste or clay is pasted over the top. The chest is then placed in a furnace and a temperature of glowing redness kept up during periods varying with the quality of steel desired. Spring steel requires seven days; shear steel, eight days; and steel for welding, from nine to ten days. When taken out the fractured bar has no longer the bluish tint of malleable iron, but has acquired a reddish-white color and a scaly, crystalline texture. A remarkable characteristic of the carbonized bars is the blistering of the surfaces, from which it gets the name of "blister steel." When the blisters are small in size and are regularly distributed the steel is of good quality; when they are large and follow certain lines it indicates a want of homogeneity in the iron used. The average increase of weight experienced by the iron during conversion is from $\frac{1}{4}$ to $\frac{1}{2}$ per cent., and the amount of coal consumed is from 75 to 90 per cent. of the weight of the steel produced. Blister steel is used for facing hammers and sledges; when drawn out at a low heat it is used for spring steel, but the texture is not sufficiently uniform for general purposes, and drawing out the bars necessarily entails a loss of carbon and, in consequence, a loss of hardness.

The proper uniformity of structure may be obtained, however, by breaking up the steel made by cementation and fusing the pieces in air-tight crucibles, from which the steel is poured into moulds, or when a large casting is to be made a number of

crucibles are emptied into one large ladle. Krupp casts ingots weighing 20 tons, using 70-lb. crucibles, the mixture in the crucibles being puddled steel, wrought iron, and carbonaceous matter. The melting hole or furnace is a rectangular cavity about 2 feet square and 3 feet deep, lined with fire-brick, with the top on a level with the floor, and the grate bars and ash-pit readily accessible from below, with a square fire-tile for a cover. A short rectangular flue is below, communicating with the chimney. A number of such furnaces are arranged in parallel lines, with spaces between for moulds. The crucibles are made of a mixture of refractory clay and coke dust and are 16 to 18 inches high, and 6 to 7 inches in diameter. Two crucibles are usually put in a furnace with charges from 35 to 80 lbs. The crucible is annealed by heating to redness in an open fire, and is then put in the furnace, and the charge of blister steel or such mixture as may be desired, the cover is put on, and the full heat of the furnace kept up for four or five hours. To tell when the charge has been thoroughly fused the cover is taken off and the inside felt with a rod, and when fused it is left at rest for a time depending upon the desired temper. The slag is skimmed from the surface and the crucible lifted out by a pair of tongs and the contents poured into a cast-iron mould, the mouth of the mould when full being covered by a shovelful of sand or a plate of sheet iron. The fuel consumed is from three to four times the weight of metal produced. The fractured surfaces of the softer *crucible steel* ingots are bright and finely granular; the harder varieties exhibit distinct crystalline plates arranged in parallel bands. The ingots are nearly always unsound, and the vesicular cavities can only be removed by reheating and hammering at a low temperature.

Musket was granted a patent in England, in 1800, for a process of manufacturing cast steel by firing malleable iron in crucibles with carbonaceous matter, and in 1839 a patent was granted William Vickers for the production of cast steel by melting 100 parts of iron borings with 3 parts of black oxide of manganese and 3 parts of ground charcoal.

Case-hardening is a rapid process of cementation by which the surface of wrought iron is converted into steel. The piece to be case-hardened is embedded in animal charcoal in a chest, and this is placed for a short time in a smith's forge or a furnace, and when taken from the fire the object is hardened by heating it to redness and plunging it while still red hot into cold water. Small articles may be so hardened externally as to resist a file, by sprinkling a little ferrocyanide of potassium on the surfaces while red hot. As soon as the powder has disappeared the article is quenched in cold water.

Instead of producing the steel by causing a certain amount of carbon to combine with wrought iron, carbon may be taken from the cast iron. The first way that this was done was in the open hearth, though improved methods have about done away with this process; but the term open-hearth steel is still used to distinguish the product of the Siemens-Martin furnace. The hearth is filled with burning charcoal and a number of plates or slabs of lamellar cast iron are melted in the blast of the tuyere, a quantity of rich slag and iron scale being added to assist in the oxidation of the carbon. About thirty cubic feet of charcoal are used per cwt. of steel produced.

Puddled steel was produced in Carinthia as early as 1835, and by 1845 it had become a staple product. There is but little difference between puddling for steel and puddling for iron (see *IRON*), except that in the latter case the decarbonization is more thoroughly effected. The crude irons that are best for this purpose are those that are rich in carbon and

manganese, so that spiegeleisens mixed with mottled pigs are very good. The furnace bed is usually smaller than in the iron furnace, to command a higher temperature with the same-sized chimney and fire-place. The charge is so distributed in small fragments that it will all become fused about the same time. The charge is from 3 to 3½ cwt. This must be perfectly fused and covered with a stratum of liquid slag to regulate the oxidation of the carbon. The melting down, stirring, or rabbling is done at a higher temperature than with the iron puddling and occupies usually from 40 to 50 minutes; the steel balls are formed, however, at a lower temperature than those of iron, and at this stage the furnace should be filled with smoke to produce a neutral or non-oxidizing atmosphere by closing the damper. The appearance of the particles of the metal brought above the slag by the stirring tells the progress of the operation and the nature of the product. When brightly granular it indicates satisfactory progress and the production of steel of fine grain and good quality. When flaky and coarsely granular the steel is likely to be coarse in texture and imperfectly refined. The shingling of the balls is conducted at a lower temperature than with iron, and when not taken immediately to the hammer are rolled in slag to prevent oxidation. The time required under ordinary circumstances to work off a heat of iron and steel will be as follows:

	Iron.	Steel.
Melting down.....	30 to 40 minutes.	40 to 50 minutes.
Stirring	30 " 35 "	45 " 50 "
Boiling and fusing... 25 " 30 "	20 " 25 "	
Balling.....	10 "	10 "
Total.....	95 to 115	115 to 135

From 1800 to 2000 lbs. of shingled steel balls can be obtained from one furnace in 12 hours, in from six to seven charges. In puddling steel, from 30 to 35 per cent. more coal will be used than the weight of steel produced. The puddled balls when under the hammer emit a blue flame, due to the combustion of carbonic oxide. To draw into bars, the blooms must be reheated before being put under the hammer, or into the rolls.

Numerous attempts have been made to produce steel cheaply, and to Sir Henry Bessemer is due the credit of discovering a quick way to convert pig-iron into steel. This process was first made public by him at the Cheltenham meeting of the British Association in 1856. This is a very simple process, and consists in charging a quantity of about five tons of melted pig-iron into a furnace shaped like a gingerale bottle mounted on trunnions, having an open top, and a bottom perforated by a number of holes, through which air is forced in small jets by a powerful blowing-engine. The blast of air, forced up through the molten metal, effects the rapid oxidation and consequent combustion of the carbon, silicon, and other foreign substances. A very high temperature is produced, sufficient to keep liquid the resulting decarburized iron, and if the blast be kept up after the carbon is all burnt out the iron itself will be burnt; so, before this point is reached, the blast is stopped, and a charge of spiegeleisen containing the necessary amount of carbon is introduced. Pig-iron of exceptional purity must be used, and it should be free from sulphur, phosphorus, and copper. The spiegeleisen is an alloy of carburized iron and manganese. This, containing about 5 per cent. of carbon and from 10 to 25 per cent. of manganese, is put in to replace the carbon that has been burnt away, and sufficient to give the required proportion of carbon in the finished metal. The converter consists of a shell of wrought iron, suspended by means of a wrought-iron hoop, B, carrying trunnions, C, supported by cast-iron stand-

ards, D, one solid carrying a pinion, E, gearing into a rack, F, worked by a small engine, for turning the converter to a horizontal position. The other trunnion is hollow, and forms a passage for the blast. The lining, A, is the most refractory material that can

FIG. 1.—Bessemer Converter.

be obtained. It is made from fine-grain silicious sandstone known as gannister. It is finely ground, and then sometimes mixed with powdered fire-brick, then incorporated with a small quantity of water, and then lightly rammed between the outside casing of wrought-iron and an inside wooden core, which is afterward withdrawn. The bottom consists of a plug of the same refractory material, with a number of holes or tuyeres, T, T, opening below into an iron box, G, which communicates with the hollow trunnion by means of a pipe, H, so that air can be blown up through the molten mass in the converter. The operation is as follows :

The charge is melted in a cupola or run direct from the blast furnace, and the converter, which has been previously heated to redness by filling it with ignited coal, is reversed to remove any unconsumed

FIG. 2.—Bessemer Converter.

fuel, and then brought to a horizontal position (Fig. 2) to receive the charge of molten metal, which is run in through an iron gutter lined with sand. The converter is then slowly turned back into the vertical position, the blast being at the same time turned on. The flame which first issues is yellowish red. Graphitic carbon passes into the combined state; the silicon becomes oxidized, and silicates of iron and manganese are formed. This first stage, which takes about five minutes, is followed by a period of violent boiling, during which the combined carbon is rapidly oxidized by the blast. Carbonic oxide being evolved in large quantities, the flame increases in brilliancy, and showers of sparks and fragments of burning iron are thrown off. This lasts for about

seven minutes, when the intensity of the action begins to diminish. Fewer sparks are given off and the flame acquires a bluish-violet tint, marking the commencement of the last stage. As soon as the carbon is all consumed the flame ceases, being immediately succeeded, however, by a flame of white-hot gas, principally nitrogen. As soon as it is seen that the carbon is about burnt out, the converter is again turned back to a horizontal position and the spiegeleisen run in from a furnace by means of a sand-lined gutter. When very mild metal is needed, the tempering is done with ferro-manganese, made hot and shovelled into the ladle while pouring. The steel is decanted from the converter by turning the top down and letting it run out into cast-iron moulds open at both ends, and a little larger at one end than the other, so that the ingots can be easily turned from them when cool.

In the Bessemer process, as described above, it is necessary to employ pig-iron containing a very minute quantity of phosphorus, as but little of that element is eliminated during conversion. This means very costly and scarcer ores; but steel can now be made by the *basic* method from iron smelted from cheap ores, the pig to be sufficiently free from sulphur, not to

contain more than one per cent. of silicon, while the phosphorus should not be less than 2 to 2½ per cent. This process is called the *basic* process, to distinguish it from the *acid* process of Bessemer. The terms refer to the lining of the converter, acid-signifying quartz or gannister, and basic lime and magnesia as existing in calcined dolomite. The chemical fact involved is that the retention of phosphorus in the blown metal is materially influenced by the character of the slag, which is a silicate of iron and manganese, and if reduced to a lower silicate by the addition of other bases phosphorus can be removed by oxidation. Lime is used for dephosphorizing after the carbon of the metal has been oxidized. When the converter is ready for charging it is made hot by a coke fire, and a quantity of quick-lime, from one-seventh to one-fifth of the weight of the charge of metal, is introduced, made as hot as possible. The metal is then charged in the usual way and the blowing conducted as already described. In about ten minutes the carbon is burnt out and the dephosphorizing period commences. This is marked by a great increase in the temperature of the bath and a thickening of the converter smoke from the burning of the iron, the flame showing peculiar bright patches which are not seen in the old process. The length of the after-blow is regulated by breaking small test-ingots, which should show a close, silky fracture, entirely free from bright crystalline particles. When the desired metal has been obtained, the converter is tipped to run off the slag, after which the metal is brought to the final temper by the addition of the proper amount of spiegel and ferro-manganese, the former in the converter and the latter in the ladle after pouring. The slag must be removed, as a portion of the phosphorus may be reabsorbed if left in contact with the metal.

There are diverse opinions as to the relative values of steel made by the acid and basic processes. The latter, utilizing the cheap ores, is remarkable for its purity and mildness, and this is likely to bring about its use on a large scale in the construction of boilers, ships, bridges, and other structures requiring toughness. The basic process is used both with the Bessemer converter and the Siemens-Martin furnace or open-hearth process.

The grandest application of the Bessemer process

is the manufacture of steel rails, though, strange to say, when granted the patent for this process he was denied the right to manufacture rails.

FIG. 3.—Open hearth Furnace.

The *Uchatius* process of making steel is to effect the partial decarburization of pig-iron by fusion in contact with ferric oxide, or some other substance

FIG. 4.—Open-hearth Furnace.

capable of yielding oxygen. The pig-iron is granulated by running the fused metal into water, and mixing the granulated metal with about 20 per cent. of roasted spathic ore and 4 per cent. of fire-clay. The mixture is then melted in clay crucibles in an ordinary cast-steel furnace.

Another method of obtaining steel is by the fusion of a mixture of cast iron and wrought, the carbon distributing itself between the two and so forming steel.

The production in a reverberatory furnace of cast-steel, by the solution of malleable scrap in molten pig-iron, has been brought to a high state of perfection by the use of the Siemens regenerative gas furnace. This is heated by gas produced in the furnace itself.

The greater part of the heat of the gases coming from the furnaces is stored in *regenerators*, and this heat is used in keeping up the temperature of the furnace. The regenerators are chambers of refractory brick placed in horizontal layers, with spaces between them

to offer a large surface of contact for the gases. There are four of these chambers, two communicating with one, and two with the other, end of the furnace. The mixture of combustible gases and air reaches the furnace F after having passed through two of the regenerators, A, A, at one end, and passing through the furnace pass out through the two regenerators A, A, at the other end, as shown by the arrows in Fig. 3. The bricks of the regenerators store up the greater part of the heat of the gases that have left the furnace, and the products of combustion pass off by the chimney D. Now, by aid of the valves, the course of the gases is reversed, and the gases pass into the furnace through the regenerators that have just been heated, and out by the ones that have been furnishing heat. In this way the gases, slowly passing through a honey-comb of hot bricks, are intensely heated, and reach the hearth at a temperature nearly that of the furnace itself, so that the combustion develops an intense heat. The temperature is raised at each reversal of the valve E, the volume of the gases being regulated by the register C, the volume of air being controlled by B, and the draught by the chimney damper D. The gas producer (Fig. 4) consists of a chamber, A, of fire-brick. D is a hopper to regulate the supply of fuel, and C a pipe for introducing water to the bottom of the furnace. The pipe E conducts the gases to the furnace.

The furnace (Figs. 5 and 6) is reverberatory, with a single door, A, on one side, and on the opposite side a tapping hole, B. The gases from the regenerators, and the air to burn them, arrive and depart at the ends C, C and E, E. A bed of iron, cooled by a current of air from below, holds the lining of sand or gannister. The furnace is heated to a white heat by the hot gas, and receives then a charge of hot cast iron, and when this is properly melted soft iron, heated to a bright red, is introduced. These additions are made about every half-hour, and the whole is then vigorously stirred. When by tests the metal is found to be sufficiently refined, red-hot cast-iron is added. Tests are made, and cast-iron added till the proper carburization is arrived at, and the product is then tapped. The operation takes from nine to eleven hours with 5 to 6-ton charges. From 13 to 14 cwt. of coal is consumed per ton of ingots.

A modification of this process is seen in the Perrot rotating furnace, which is made with an inclined bed, as shown, and when rotated the molten metal flows from side to side, the bed standing under the arch of the reverberatory furnace, and over the regenerators. From two to four revolutions are made per minute, and as the pieces of the charge are con-

FIG. 5.—Open-hearth Furnace.

tinually changing from exposure to the flame to full immersion the fusion is very rapid, and the bottom, being exposed to the flames at short intervals, is

kept at a high temperature, so that there is no sticking of the charge to the bottom. These furnaces are extensively used in this country.

The steel used in the vessels now constructing for the U. S. navy is made in ordinary Siemens-Martin furnaces, Bessemer steel not as yet being used for this purpose, though basic steel is used extensively for ship rivets.

The basic method of dephosphorization is now being extensively used in the manufacture of steel in

Allen, of the Bessemer Works, Sheffield. He inserts a two-bladed propeller on the end of a vertical shaft into the ladle just before casting, and stirs the metal, liberating the gases and thoroughly incorporating all parts.

This country can now produce within its borders all the iron ore needed in every branch of its iron and steel industries, including the finer grades of crucible steel. We have ores in great abundance for the manufacture of acid Bessemer steel, but they are confined to comparatively limited areas. We have beds of ore for the manufacture of spiegeleisen and ferro-manganese, that would place our country on a self-sustaining basis, in case the foreign supply should be interrupted. But the spiegeleisen is not a large item in the manufacture of steel, and it is more economical now to import it. Great Britain is entirely without manganese iron ore deposits. The first steel of any kind produced in the South was made with the Henderson Steel and Manufacturing Company's open hearth furnace at Birmingham, Ala., Feb. 27, 1888.

In 1887 the United States produced 47,598 tons of spiegeleisen. Ore of a character suitable for the manufacture of spiegeleisen was discovered in Independence Co., Ark., and railroad connections with this region were completed in 1887, though all the ore shipped in that year, 926 tons, was sent to the Edgar Thompson furnaces at Braddock, Pa. Our production of spiegeleisen since 1875 is as follows:

Years.	Tons.	Years.	Tons.
1875.....	7,832	1882.....	21,963
1876.....	6,616	1883.....	24,574
1877.....	8,845	1884.....	33,833
1878.....	10,674	1885.....	34,671
1879.....	13,931	1886.....	47,983
1880.....	19,603	1887.....	47,598
1881.....	21,086		

the open-hearth furnace, a bed of shrunk dolomite or magnesia being substituted for that of gannister used in the Siemens process.

In casting steel in large masses, whether from crucibles, Bessemer converters, or open-hearth furnaces, it is often difficult to obtain sound ingots, especially when the steel is a mild one, the upper part usually being honey-combed to a greater or less degree—due probably to the escape of carbonic oxide or hydrogen gas. The necessary consolidation of ingots intended for rolling or forging is effected by subjecting the metal while in the mould to hydrostatic or gaseous pressure until it sets, preventing in this way the escape of gas, or else giving the gas a chance to escape by stirring or pouring from one ladle to another. Sir Joseph Whitworth applies

The iron and steel production of the United States has been subject to periods of depression, and at times it has been necessary for the manufacturers to regulate the production to bring about a healthy state of trade; for in times of booms the manufacture is apt to be carried to such an extent as to exceed the demand. The year 1887 was the most active year in the history of the American steel and iron trade, the following table showing the production in that year as compared with 1885 and 1886.

Products.	Tons of 2000 lbs.		
	1885.	1886.	1887.
Pig iron.....	4,259,860	6,635,938	7,187,206
Bessemer steel ingots.....	1,701,762	2,541,493	3,288,357
Bessemer steel rails.....	1,074,607	1,763,667	2,354,139
Open hearth steel ingots...	149,341	245,250	360,717
Open hearth steel rails....	4,793	5,255	19,203
Crucible steel ingots.....	64,511	80,609	84,421
Rolled iron except rails...	1,789,711	2,259,943	2,565,438
Iron rails.....	14,815	23,679	28,662
Kegs cut nails (100 lbs.)...	6,696,815	8,160,973	6,908,870
Pig, scrap, and ore blooms.	41,700	41,909	43,306

This table shows a wonderful progress, such as has never been witnessed in other great industries of this or other countries. In the two years from 1885 to 1887 we increased our production of pig iron 58 per cent., of Bessemer steel ingots 93 per cent., of Bessemer steel rails 119 per cent., of open hearth steel ingots 141 per cent., and of rolled iron 43 per cent. In these two years over 21,000 miles of new

FIG. 6.—Open-hearth Furnace.

FIG. 7.—Pernot Rotary Hearth.

the first method on a large scale; his *fluid compressed steel* being subjected to a pressure, while melted, of from 6 to 20 tons per square inch. The density of metal is increased about $\frac{1}{4}$ per cent. over that cast in the open moulds. At Pittsburg steam has been used, and Krupp uses liquid carbonic acid to supply the pressure. In the former the mould is covered by a closed lid wedged down to form a steam-tight joint, and this communicates by a flexible pipe with a steam-drum supplying steam at a pressure of from 80 to 150 lbs. per square inch, which is allowed to act till the metal has set.

The most noticeable method of producing homogeneity in molten metal by agitation is that of Mr.

railroad were constructed, for 1886, 8999 miles, and for 1877, 12,500 miles. These new roads demanded steel rails, tools, locomotives, bridges, and cars, all using steel, and the general prosperity of the country created an extensive demand in manufacturing, agricultural, and other enterprises requiring the use of iron and steel. Old roads, finding their trade heavier, put in steel rails and built heavier bridges. Congress appropriated large sums of money for new vessels, armor, and guns, all requiring steel of the very best quality in vast quantities. The population increased by about a million, and these required steel for domestic and other purposes. Finally, iron and steel were much used in the building of new iron and steel works in the South. Notwithstanding the great demand, the prices were kept within reasonable limits. The year 1888 started badly on account of freight-rate wars, strikes, the blizzard, and the uncertainty as to the tariff. These affected the earnings of the roads, but the consumption of steel for miscellaneous purposes, and the manufacture of steel rails for renewals, extensions, and new roads, was large. The bridge-works, the foundries, the machine shops, the car builders, the car-wheel manufacturers, and the locomotive builders are still very busy.

Imports of Iron and Steel.

Commodities.	Tons of 2000 lbs.			
	1884.	1885.	1886.	1887.
Pig iron.....	206,281	164,349	405,180	523,635
Scrap iron.....	50,192	15,480	97,625	351,022
Scrap steel.....	8,328	2,196	11,263	29,716

Total.....	733,260	647,806	1,230,303	1,897,241

The foreign value of the imports of iron and steel manufactures, represented in the above table, together with machinery, cutlery, firearms, and other articles whose weights were not obtainable, was \$56,420,607 in 1887, and \$41,630,779 in 1886. The value of the iron ore imported in 1887 was \$2,206,958, and in 1886 it was \$1,912,437. The imports of pig iron in 1887 included 176,153 tons of spiegeleisen. We import iron ore principally from Spain, Elba, Algeria, and Cuba.

Exports of Iron and Steel.

Our iron and steel exports consist principally of finished articles ready for use, such as firearms, printing presses, hardware, axes, saws, and other tools, shovels, scales and balances, sewing machines, locomotives, and other steam engines, boilers, stoves and ranges, machinery, car wheels, castings, etc. We do not export much pig iron or rails, but in 1887 we exported 55 locomotives. In 1887 we exported \$2,427,835 worth of mowers, reapers, ploughs, and cultivators. The following table gives the values of the exports of iron and steel:

Year.	Value.	Year.	Value.
1871.....	\$14,185,350	1880.....	\$15,156,703
1872.....	12,595,539	1881.....	18,216,121
1873.....	14,173,772	1882.....	22,348,834
1874.....	17,312,239	1883.....	22,716,040
1875.....	17,976,833	1884.....	19,290,895

1879.....	14,223,646		

Production of Bessemer Pig in 1887.

States.	Tons.	States.	Tons.
Pennsylvania.....	1,842,449	New York.....	62,626
Illinois.....	549,111	Colorado.....	23,125
Ohio.....	331,144	Maryland.....	18,473
Missouri.....	122,725	Michigan.....	12,766
Wisconsin.....	109,585	Tennessee.....	11,500
West Virginia.....	73,070		
New Jersey.....	63,773	Total.....	3,220,517

A large part of the Bessemer pig produced in the Lehigh and Schuylkill Valleys, and in Maryland, New York, and New Jersey, is made from foreign ores, or foreign ores mixed with native ores.

Furnaces.—The number of steel and iron furnaces in blast in the United States at the close of 1884 was 236; on June 30, 1885, 228; on June 30, 1887, 306, and at the end of 1887, 339. At the close of 1887 there were 583 furnaces in the United States, and 30 new furnaces in course of erection.

Production of Steel.—The production of Bessemer steel ingots in the United States in 1887 was 3,288,357 tons, a gain of 746,864 tons over the production of 1886, nearly double the production of 1885; about seven-eighths of our total production for this year being made by the Bessemer processes. Eleven States contributed to this production, Massachusetts, New York, Pennsylvania, Virginia, West Virginia, Tennessee, Ohio, Indiana, Illinois, Missouri, and Colorado, there being 41 works with 86 converters employed. In 1887 there were 2,290,197 tons of Bessemer steel rails produced.

The open hearth steel production of 1887 was 260,717 tons, an increase of 115,467 over that of 1886. This was made in nine States, by 39 plants. The number of open hearth steel works at the end of 1887 was 53, with 104 furnaces. There were 19,203 tons of steel rails by the open hearth process in 1887. The States producing open hearth steel are New Hampshire, Massachusetts, New York, New Jersey, Pennsylvania, Ohio, Indiana, Illinois, California, and Alabama.

The production of crucible steel in 1887 was 84,421 tons against 80,609 tons in 1886. This was made in ten States—Massachusetts, Connecticut, New York, New Jersey, Pennsylvania, Maryland, Tennessee, Ohio, Illinois, and Michigan.

The production of steel by various minor processes amounted in 1887 to 6265 tons, blister, puddled, and malleable cast steel being included.

In 1887, 2,373,335 tons of steel rails were produced, an increase of 603,796 tons over 1886. These were produced in fifteen States, Pennsylvania furnishing 54 per cent., and Illinois 30 per cent. In 1887 there were 57,362 tons of street rails produced.

The production of steel by all processes in Great Britain and the United States, in 1887, was as follows:

Ingots.	Great Britain.	United States.
Bessemer Steel.....	2,034,403	2,936,033
Open hearth steel..	981,104	322,069
Crucible steel.....	About 100,000	75,376
Other steel.....	Nominal if any	5,593
Total.....	3,545,507	3,339,071

The Presence of Foreign Substances in Steel.—The carbon of course regulates the kind of steel. When it amounts to .04 of one per cent. we get a tensile strength per square inch of about 50,000, increasing to 150,000 lbs. as the carbon rises to .9 of one per cent. Manganese is used up in eliminating more injurious substances in the ore. For example, combining with protoxide of iron, it helps to remove this very injurious oxide, reducing it to iron and oxide of manganese, which passes off in the slag. The presence of much manganese makes the steel very hard and stiff. In plates for ships it varies from .22 to .60 per cent.

Phosphorus tends to make the steel non-homogeneous by being unequally distributed, to make it "cold-short" or brittle when worked cold, and tends to weaken steel that is reheated or subjected to vibration, so that it must be kept below .06 per cent. in ship plates, shapes, and rivets, and below .03 per cent. in boiler stays, plates, and rivets. Pig containing phosphorus is very cheap, and the phosphorus helps in the melting and pouring of the metal, and gives a good elastic twist and strength with less work on the material. So there is naturally a strong temptation to use it on account of cheapness, and the basic processes are apt to rapidly grow in favor. In bridge steel phosphorus is not permitted to be above .05 per cent., and in rails it is limited to .10 per cent.

Silicon tends, in solid castings, to prevent blow-holes and sponginess. The silicon is usually consumed in the furnace when making mild steel, and in ship-plates does not amount to more than .04 per cent.

Sulphur is very injurious, leading to hot short-

facture of steel is in the making of malleable steel castings; the heavy ram sterns, stern-posts, rudder-posts, and struts, that had until recently to be forged out are now cast, and such castings are to show a tensile strength of 60,000 lbs., and an elongation in 8 inches of 10 per cent.

Boiler shell plates are tested the same as the ship plates, but the gauge plates are to have an elongation of 29 per cent. in 8 inches.

In the case of gun steel and steel for armor, the specimen is 2 inches between witness marks, cylindrical in shape, $\frac{1}{4}$ inch in diameter. For protective decks the steel to be between 60,000 and 70,000 lbs. and 25 to 23 per cent. elongation, or between 70,000 and 80,000 lbs. with 23 to 19 per cent. elongation, or between 80,000 and 90,000 lbs. with 19 to 12 per cent. elongation. For heavy steel armor, the tensile strength to be 82,000 lbs. and the elongation not less than 20 per cent. Gun steel must be of the very best, and there are tests for the various parts of the gun, the tests for the 8-inch gun being given as an example.

	Tubes.			Jackets.			Hoops.		
	A.	B.	C.	A.	B.	C.	A.	B.	C.
Tensile strength (pounds)	80,000	72,000	70,000	85,000	76,500	74,000	100,000	90,000	90,000
Elastic limit (pounds)	38,000	34,000	33,000	40,000	36,000	34,000	50,000	45,000	45,000
Elongation (per cent.)	20	18	13	18	15	10	18	16	13
Contraction of area	30	20	15	30	20	12	30	25	15

ness or brittleness when worked hot. It is not above .03 per cent. in ship steel. Arsenic makes steel cold-short, copper red-short, and antimony both red- and hot-short.

Tests.—Steel is now subjected to rigid tests before being used for structural purposes. For the mild steel which is used for the vessels now building for the Government, test pieces are taken about 16 inches long, with witness marks about 8 inches apart, the sectional area being from .5 to .8 of an inch. These pieces are placed in the testing-machine and subjected to a pull, the amount of which can be accurately measured in pounds. The specimens are first carefully measured to get the exact sectional area, the micrometric gauges used measuring to .001 inch. An initial stress of about 30,000 lbs. to the square inch and kept in continuous action for about a minute, and observations taken to note the corresponding elongation. The weight is then increased gradually, till the cracking of the mill-scale and the unsteadiness of the beam show that the elastic limit is being neared; and when the beam drops suddenly, the weight is recorded as the elastic limit. From this time loads are gradually added till the specimen is broken. The load necessary to produce ultimate fracture is carefully noted and the pieces fitted carefully together, and the increased distance between the witness-mark measured to obtain the elongation. Plates and the shapes, as they are called, such as angle steels, Z bars, bulbs, etc., must show an ultimate tensile strength of 60,000 lbs. to the square inch, and an elongation in 8 inches of 25 per cent. Pieces cut from the finished heat must bend over flat on themselves when cold without breaking, and specimens, after being heated to a dark cherry-red and then plunged into water at 82° F., must bend round a curve whose diameter is $1\frac{1}{2}$ times the thickness of the plate, without cracking. Rivets are to have a tensile strength of from 50,000 to 55,000 lbs. per square inch, and an elongation in 8 inches of not less than 30 per cent., and they must flatten out cold under the hammer to a thickness of one-half the diameter, and hot to a thickness of one-third the diameter, and bend in the form of a hook when cold without showing cracks or flaws.

One of the most important advances in the manu-

Material is, of course, subject to a rigid surface inspection for laminations, hair-cracks, scale-marks, blisters, pits, snakes, and cobbles. Pits should cause rejection, being due to burning. They occur in the form of small cup-like holes, and must not be confounded with cinder-spots, which are due to cinders or pieces of firebrick being rolled into the plates. Cracks are due to rolled-out blow-holes, while snakes are small lines twisting in every direction, due to foreign substances in the heat separating two masses of pure steel. This should always cause rejection. Cobbles are irregularities due to one side being more heated than another.

Ship plates and shapes can be bought, which will pass the above tests, for about 3.34 cents per lb. Steel castings cost about 16 cents a lb. Steel forgings for guns cost about 30 cents a lb., though the price depends very much on the size, and twelve-inch armor-plates cost about \$675 per ton. Steel rails are now worth about \$27 per ton.

The recent additions to the U. S. navy comprise ten steel-protected vessels, begun in 1887: the Baltimore, Newark, Philadelphia, Vesuvius, and Yorktown, built at Cramps' ship-yard, Philadelphia; the Bennington and Concord, built at Roach's yard, Chester, Pa.; the Petrel, built at the Columbian Iron Works, Baltimore; and the Charleston and San Francisco, built at the Union Iron Works, San Francisco. In 1888 two armored cruisers were commenced—the Maine, at the New York navy yard, and the Texas at the Norfolk navy yard. The Newark, one of the largest, is a twin-screw, steel-protected cruiser of 4083 tons displacement. She is 328 ft. long, 49 ft. beam, and 18 $\frac{1}{2}$ ft. mean draught. The engines, boilers, magazines, shell-rooms, torpedo spaces, and steering gear are protected by a thick steel deck, resembling a turtle-back, extending fore and aft, and dipping below the water at the sides and ends. The speed is to be 18 knots, and she will carry twelve 6-in. breech-loading rifle guns. The contract price for hull and machinery is \$1,248,000.

In the preparation of this article the following have been drawn from: *The Elements of Metallurgy*, by J. Arthur Phillips; *The Inspection of Structural and Boiler Material*, by Lieut.-Commander J. G. Eaton, U. S. N.; and the *Report of the American Iron and Steel Association*. (L. N.)

STEELE, FREDERICK (1819-1868), general, was born at Delhi, N. Y., Jan. 14, 1819. Graduating at the U. S. Military Academy in 1843, he served in the war with Mexico as 2d lieutenant, gaining the brevets of 1st lieutenant and captain by his "gallant and meritorious conduct" at Contreras and Chapultepec. In June, 1848, he was commissioned as 1st lieutenant and ordered to California, where he served till 1853, and thereafter mainly in Minnesota, Nebraska, and Kansas till the civil war, receiving his commission as captain in 1855. In June, 1861, he was advanced to major of the Eleventh Infantry, and in September to colonel of the Eighth Iowa Volunteers, commanding a brigade in Missouri till April, 1862, and taking part in the battles of Dug Spring and Wilson's Creek. He was commissioned brigadier-general of volunteers in January, 1862, and commanded a division in the Army of the Southwest till November of that year, being engaged at Round Hill and in the occupation of Helena, Ark. He was then brevetted to major-general of volunteers and assigned to the Thirteenth Army Corps, which he commanded in the Yazoo expedition and at the capture of Arkansas Post, in January, 1863. Transferred to the Fifteenth Corps, he led a division in the Vicksburg campaign, for his various services in which he was brevetted colonel in the U. S. army, July 4, 1863, and promoted to lieutenant-colonel, Aug. 26, when his division was sent to Arkansas and, Sept. 19, captured Little Rock, from which date till Nov. 29, he commanded the department of that State. He then went to the aid of Gen. Canby in the reduction of Mobile, and, after commanding various divisions in the South, was at the close of the war brevetted brigadier-general in the regular army for the capture of Little Rock, and major-general for services during the war. In December, 1865, he was assigned to the command of the Department of Columbia. On July 28, 1866, he was assigned to the colonelcy of the Twentieth Infantry, and remained in the service till mustered out in March, 1867, on account of failing health. He died at San Mateo, Cal., Jan. 12, 1868.

STEENSTRUP, JOHANN JAPHET SMITH, Danish naturalist, was born, March 8, 1813, at Vang, where his father was pastor of a Lutheran church. He studied medicine but devoted himself especially to natural science, making for this purpose visits to the island of Bornholm (1836), to the north of Jutland (1838), to Iceland (1839-40), to the Scotch Highlands, Faroe Islands, and Norway (1844). In 1843 he obtained the natural history prize offered by the University of Copenhagen. He had already been instructor in mineralogy and botany at Soroe, and in 1845 he was made assistant professor of zoology in the University of Copenhagen, and in 1848 one of the directors of the Royal Museum of Natural History in that city. His works on *The Development of Animals by Alternations of Generation* (1842) and *Researches on Hermaphrodites* (1846) are important contributions to science and have been translated into English and other languages.

STEFFENS, HEINRICH (1773-1845), German philosopher, was born at Stavanger, Norway, May 2, 1773. He studied the natural sciences at Copenhagen, and went thence to Germany to follow the course of Schelling at Jena. On his return to Copenhagen he opened a course of lectures on philosophy, which was promptly suppressed owing to the startling novelty of his ideas. By way of compensation he accepted the chair of philosophy and mineralogy in the University of Halle. A determined foe to the French invasion of Germany, he served through the campaign of the War of Liberation, and after the peace returned to Breslau to teach the natural sciences. He was then called to Berlin to occupy the chair of natural sciences in the university of that city, and for a year occupied the position of

rector of the university. His principal works are: *The Principles of the Philosophy of Nature* (Berlin, 1806); *Anthropology* (Breslau, 1821); *The False Philosophy and the True Faith* (Breslau, 1825); *Christian Philosophy* (Breslau, 1835). He died at Berlin, Feb. 13, 1845.

STEIN, LORENZ, Danish jurist and economist, born at Eckernförde, Nov. 18, 1815. The son of a soldier and left an orphan at an early age, he was brought up as a "child of the regiment" at a military school, where he so distinguished himself by his intelligence and progress that he received a bursary from the king by which he was enabled to continue his studies at the Flensburg School of Science and at the Universities of Kiel and Jena, where he applied himself specially to the study of philosophy and jurisprudence. In 1841 he took his degree at Kiel, and published a *History of Civil Procedure and Present Practice in Denmark* which gained for him a prize from the government that enabled him to visit Berlin and Paris, where his attention was mainly directed to Saint-Simonism. He was thus led to publish a pamphlet upon *Socialism and Communism in Modern France* (Leipsic, 1844), in which the socialist theories were for the first time submitted to a really scientific examination. In Paris, also, he collected materials for his *History of the French Constitution and Law* (3 vols., 1846-48). Meantime he had been created Doctor by the University of Kiel, and in 1846 was appointed professor extraordinary there. When the Schleswig-Holstein question came to be agitated he warmly defended the rights of the duchies in the German press. He took part also in editing the pamphlet of the nine Kiel professors, and saw himself, thereupon, threatened with deprivation. On the rising of the duchies in 1848 he sustained the national cause with more ardor than ever, and was sent by the provisional government to Paris, where he brought out a pamphlet on *The Schleswig-Holstein Question*. Here also he revised his work on the social condition of France, which he brought out anew under the title: *History of the Social Agitations in France from 1789 to the Present Time* (Leipsic, 1849-51, 3 vols.). From this time he devoted himself more especially to economical questions proper, and, having, along with his nine colleagues, been deprived of office on Denmark retaking possession of the duchies in 1852, lived privately in Kiel till 1854, when he repaired to Vienna. Here he was appointed to the chair of the political sciences and became associated with the Minister of State Von Bruck, who called on him for assistance in regard to the Austrian finances. In 1878 he was appointed professor in the law faculty of the University of Vienna, and held this chair till his retirement in 1885. Among his works are: *A System of the Political Sciences* (Stuttgart, 1852-56); *The New Conditions of Specie and Credit in Austria* (Vienna, 1855); *Manual of Political Economy* (Vienna, 1858); *Manual of the Science of Finance* (Leipsic, 1860); *Science of Administration* (Stuttgart, 1865-68); *Army Administration* (1872); *Woman in National Economy* (1886).

STEPHEN, SIR JAMES FITZJAMES, English lawyer and legal author, was born in London in March, 1829, being the son of Sir James Stephen, for whom see *ENCYCLOPEDIA BRITANNICA*. He was educated at Trinity College, Cambridge, graduated B. A. in 1852, and was called to the bar at the Inner Temple in January, 1854. He served as recorder of Newark-on-Trent from 1859 to 1869, and in December of the latter year was appointed a law member of the government of India in place of Sir Henry Maine. He held this office till April, 1872, during which time he strove to simplify the laws of India. In 1873 he unsuccessfully contested Dundee, in 1875 was appointed professor of common law of the Inns of Court, and in 1878 became a member of the royal

commission to inquire into the provisions of a draft code relating to indictable offences. In 1879 he was appointed a judge of the High Court of Justice. He has been an active writer on legal subjects, his principal works being *Essays by a Barrister* (1862); *General View of the Criminal Law* (1863); *Liberty, Equality, and Fraternity* (1873); *Digest of the Law of Evidence*, and *Digest of the Criminal Law* (1877), the latter works forming the basis of a bill on indictable offences; and *History of the Criminal Law of England* (3 vols., 1883).

His brother, LESLIE STEPHEN, noted as an author, was born in London, Nov. 28, 1832. He was educated at Eton; King's College, London; and Trinity Hall, Cambridge, where he graduated B. A. in 1854 and M. A. in 1857. He was a fellow and tutor in Trinity Hall for several years, but left Cambridge in 1864 and entered actively into literary pursuits in London. He married Harriet M. Thackeray, daughter of the novelist, and in 1871 became editor of the *Cornhill Magazine*, and continued in charge of it till 1882, when he resigned for the purpose of taking up the extensive work upon which he has been since engaged, the *Dictionary of National Biography*. In May, 1883, Mr. Stephen was elected to the lectureship of English literature at Cambridge. In addition to his editorial and professional work Mr. Stephen has been an active writer, and has contributed largely to the literature of Alpine travel, which he has treated in *The Playground of Europe* (1871). In addition, his works include *Essays on Free Thinking and Plain Speaking* (1873); *Hours in a Library* (3 series, 1874-79), a collection of acute literary criticisms; *History of English Thought in the Eighteenth Century* (1876); *The Science of Ethics* (1882); and *Lives of Johnson, Pope, and Swift in the "English Men of Letters" series*. He edited Fielding's *Works* in 10 volumes, with a biographical essay, in 1882, and has contributed numerous articles to the *Saturday Review* and the *Pall Mall Gazette*. The *Dictionary of National Biography* in which he is assisted by many distinguished writers, is the most complete and accurate work in its special field.

STERLING, a city of Illinois, in Whiteside county, is on the N. bank of Rock river, 109 miles W. of Chicago. It is on the Chicago and Northwestern Railroad, and on a branch of the Chicago, Burlington and Quincy Railroad. Rock river is here crossed by two bridges, one being of iron, 1100 feet long, and costing \$40,000. There is a large dam which furnishes water-power to nearly all the factories, 44 in number. They produce agricultural implements, wagons, carriages, barbed wire, paper, pumps, windmills, and other articles. There are five iron foundries. Sterling has a city hall, 2 hotels, theatre, 3 fine public school buildings, 15 churches, a free public library. It was settled in 1834, and incorporated in 1858. Its property is valued at \$7,000,000. It is surrounded by a rich agricultural district, inhabited by a highly moral community. The population of Sterling in 1880 was 5087.

STEBEN, FRIEDRICH WILHELM AUGUST HEINRICH FERDINAND VON, BARON, a German soldier of distinction in our war of the Revolution, was born, Nov. 15, 1730, in the fortress of Magdeburg, Prussia, where his father was a captain. After finishing his education in a Jesuit college at Neisse and Breslau, he entered the Prussian service in 1747 as cadet in an infantry regiment, and was made ensign in 1749 and lieutenant in 1753. He served in the Seven Years' war and was wounded at the battle of Prague, and distinguished himself at Rosbach. In 1758 he was made adjutant-general, and in 1759 took part in the battles of Kay and of Kunersdorf, where he was again wounded. He was aide to Gen. Knoblauch in his brilliant march into Poland in 1761, and was taken prisoner by the Russians, but was exchanged,

and in 1762 made aide to Frederick the Great, in which capacity he was present at the siege of Schweidnitz, the closing scene in the Seven Years' war. At the peace of 1763 he withdrew from the army, and was presented by Frederick with a valuable lay benefice. He accompanied the Prince of Hohenzollern-Hechingen to several of the courts of Europe, and was by him made grand marshal and general of his guard, which posts he filled for 10 years. In 1777, while on a visit to France, he was induced by Count St. Germain to offer his services to the struggling American colonies, through the agency of Silas Deane. In December, 1777, he set sail with several other officers from Marseilles, and after a perilous passage arrived, in 55 days, at Portsmouth, N. H. Hence he wrote to Congress, offering his service, and saying that the sole motive that brought him was to "serve a nation engaged in the noble work of defending its rights and liberties." Proceeding south he presented himself to Congress at York, Pa., and proposed to enter the patriot force as a volunteer, on the conditions that if his "services were not satisfactory, or if the colonies failed to establish their independence, he was to receive nothing," but if they were successful "he was to be refunded the income he had given up, and be remunerated for his services." His offer was accepted and he proceeded at once to Valley Forge, where he was gladly welcomed by Washington. On looking at the wintry encampment and observing the half-starved, half-clad, and poorly armed soldiers crawling out from their huts, he declared that "no European army could be kept together a week in such a state." He set to work at once, and from that hour our military system assumed a new shape. In May, 1778, Congress appointed him inspector-general of the army, with the rank of major-general, and he took part as a volunteer in the battle of Monmouth in the following June. His services in drilling the officers and men of the army can scarcely be overrated. In 1779 he submitted to Congress a manual of instruction, which, being approved, contributed to introduce a thorough system of discipline. In 1780 he sat as a member of the court-martial that tried Major André, and in the same year was placed in command of the troops in Virginia, at the head of which he was busy in the beginning of 1781 in harassing the British under Gen. Arnold. At the siege of Yorktown Steben took his place as a major-general of the line, and was attached to Gen. Lafayette's division. He was in the trenches when the proposition to surrender arrived, and when Lafayette came to relieve him he refused to leave his post, declaring that the rules of war required that the officer who received the first overtures of surrender must keep his post till terms were agreed on or hostilities resumed. Remaining as a citizen of the United States after the war, he took up his abode in New York City, where he resided for several years. It was only after 7 years' struggle that he succeeded in getting Congress to fulfil its contract, which it did by granting him a pension of \$2,400. Meantime several States had presented him with grants of land. New York gave him a township (now called Steben) near Utica, Oneida Co., and here he built himself a log-cottage, in which he spent the remainder of his days, in the company of North, Popham, Walker, and other of his aides. His lands covered 16,000 acres, but of these he gave away large tracts in gifts to poor soldiers, passing the evening of his life in the healthful occupations of a simple farmer. He died at his cottage, Nov. 28, 1794, and according to his own request was buried near it with the star of honor that he always wore on his breast. A life by Francis Bowen appeared in Sparks' *American Biography*, but a superior one was published by Friedrich Kapp in 1866. (J. H.)

STEUBENVILLE, a city of Ohio, county seat of Jefferson Co., is on the Ohio river, 22 miles above Wheeling. It is on the Cleveland and Pittsburgh, and the Pittsburg, Cincinnati and St. Louis Railroads, which here cross the river on a bridge. It has a fine court-house, 3 national banks, 2 other banks, 18 churches, a high school and other schools, 2 daily and 4 weekly newspapers. The industrial works comprise iron rolling-mills, blast furnaces, car-works, machine-shops, white-lead works, breweries, glass factory, paper, flour, and woollen mills, and potteries. It is adjacent to bituminous coal-fields, and has a good supply of natural gas. It is also a trade centre for a farming and wool-growing district. Fort Steuben was erected here in 1787, and the settlement which grew around it was made a city in 1851. Its population in 1880 was 12,033.

STEVENS, ISAAC INGALLS, general, was born, March 28, 1818, at Andover, Mass., and was graduated in 1839 from the U. S. Military Academy, where he ranked first in his class, being commissioned 2d lieutenant of engineers. In 1840 he was promoted 1st lieutenant, and served as adjutant of the engineer corps in the Mexican war, in the course of which he was brevetted captain and major for meritorious conduct at Contreras, Churubusco, and Chapultepec. At the taking of the City of Mexico he was severely wounded. For several years he superintended fortifications on the New England coast, and from 1849 to 1853 was principal assistant and in charge of the office of the U. S. Coast Survey at Washington, D. C. In the latter year he resigned from the army on his appointment to the governorship of Washington Territory. While continuing to hold this office he conducted the pioneer survey of the northern route for a Pacific railroad, an account of which he afterward published. In virtue of his office of governor he was superintendent of Indian affairs, in which capacity he had frequent dealings with the natives, as well as hostile encounters with them. In 1854-55 he concluded treaties with them by which they relinquished more than 100,000 square miles of territory. During his absence, in the latter year, the disaffected Indians rose against the whites. On his return he called out 1,000 volunteers, and after a campaign in 1856 the Indians were subdued and their chiefs slain. During the struggle he caused whites sympathizing with the savages to be shut up in the towns, and when Chief Justice Lander issued a writ of *habeas corpus* for their release, Stevens declared two counties under martial law, seized Lander in his court-room, and kept him prisoner till the end of the war. In 1857 he resigned his governorship and was elected delegate to Congress from Washington Territory for two successive terms (1857-61). On the outbreak of the civil war he hastened from the Pacific coast to Washington, and was appointed colonel of the 79th (Highlanders) N. Y. Volunteers. The men were disappointed at being commanded by army officers and 8 companies mutinied, but by his courage and sound sense Col. Stevens restored discipline, and on his promotion to brigadier-general, Sept. 28, 1861, the men asked to be transferred to his brigade. His first service in this capacity was in the Port Royal expedition, which left Fortress Monroe a month later, in the course of which he, with the co-operation of the gun-boats, attacked and captured the Confederate batteries on the Coosaw. On July 4, 1862, he was promoted to major-general of volunteers, and transferred to Newport News, serving under Gen. John Pope. He took part in skirmishes on the Rappahannock, and was hotly engaged in the second battle of Bull Run, where he distinguished himself. On the morning of Sept. 1, 1862, his division encountered the enemy near Chantilly. Stevens, carrying the colors of the 79th Regiment in his hand, placed himself at the head of his divisions,

and cheered on his men; while thus engaged he was shot through the head and instantly killed.

STEVENS, JOHN (1749-1838), inventor, was born in New York in 1749. His specialty was the problem of steam-navigation. The legislature of the State of New York had offered a monopoly of the navigation of the Hudson to anyone who should construct a boat with a speed of 3 miles an hour, and, as early as 1789, Stevens presented a memorial stating that he had perfected his plans. In 1804 he built a vessel with twin screws that navigated the Hudson, but failed to attain the required speed. Livingston (Stevens' brother-in-law) and Fulton then acquired the monopoly. In 1807 Stevens built the paddle-wheel steamer *Phoenix*, that plied for six years on the Delaware. Professor Renwick, who gives the best account of Fulton's boat Clermont, in 1807, says: "The Stevenses [father and son] were but a few days later in moving a boat with the required velocity," and, "being shut out of the waters of New York by the monopoly of Livingston and Fulton, Stevens conceived the bold design of conveying his boat to the Delaware by sea, and this boat, which was so near reaping the honor of the first success, was the first to navigate the ocean by the power of steam." In 1812 Stevens designed a revolving, iron-plated steam battery, essentially on the principle afterward embodied in the monitors. In the same year he published an essay on railroads, indicating the methods of operating them by steam, and suggested the building of a railway between Albany and Lake Erie. He was the engineer of the Camden and Amboy Railroad. To Stevens may be ascribed the paternity of the American patent law. In 1790 his petition to Congress for protection to American invention was referred to a committee, which reported a bill that became law, April, 1790. He died at Hoboken, N. J., March, 1838.

His son, **ROBERT LIVINGSTON STEVENS** (1787-1856), was born at Hoboken, N. J., March, 1787. From his 17th year he was associated with his father in experiments in steam-navigation and ship-building. In the hull of his father's vessel the *Phoenix*, which he navigated from New York to the Delaware in 1808, he introduced concave water-lines, this being the first application of the wave-line in ship-building. During the war with England he was engaged, in 1813-14, in making a bomb that could be fired from a cannon instead of from a mortar, and ultimately sold to the government percussion oblongated shells for smooth-bore guns. On Fulton's death, in 1815, the speed attained by steam-boats on the Hudson was under 7 miles an hour; about this date Stevens produced the Philadelphia, with a rate of 8 miles. From this time till 1832 he kept accelerating the rate, till the North American attained 15 miles. In 1821 he originated the present form of ferry-boats and ferry-slips. In 1822 he introduced anthracite into his furnaces, and, soon after, into his steamers. In 1836 he introduced the T-rail on the Camden and Amboy Railroad, of which he was president. In 1842 he was commissioned by government to build an iron-plated war-vessel or battery, shell-proof, and to be driven by screws. This was left unfinished at his death, which occurred at Hoboken, April 26, 1856.

JAMES ALEXANDER STEVENS, brother of the preceding, was born in New York in 1790, graduated at Columbia College in 1808, and was admitted to the New York bar, 1811. He also was connected with steam-navigation, and, in conjunction with Thomas Gibbons, established the Union Line between New York and Philadelphia. This resulted in a suit, memorable for its decision, that placed all the waters of the United States under government jurisdiction.

EDWIN AUGUSTUS STEVENS (1795-1868) was associated with his brothers in steam-navigation, and in

conjunction with them established passenger and tow-boats on the Hudson and other rivers. On the outbreak of the civil war he and James A. offered to complete the iron-clad battery left unfinished by their brother Robert, on condition that government should remunerate them for their outlay in the event of its proving a success; and, for the purpose of showing the reasonableness of the proposal, they fitted out, at their own cost, the little iron-clad Naugatuck, which rendered valuable service in engagements on the James River. Nevertheless the offer was declined, whereupon Edwin himself expended considerable sums on the battery, and on his death bequeathed it, with \$1,000,000 to complete it, to the State of New Jersey. This sum proving insufficient, the vessel was sold by the State in 1874 to the U. S. government, but, Congress having failed to make the appropriation for the purchase, it remained at the dock of Hoboken uncompleted. At an early period Edwin purchased the entire site on which the city of Hoboken is built, by which, as well as by his other enterprises, he acquired an immense fortune. He endowed the Hoboken high school, and bequeathed in all nearly \$1,000,000 to establish the Stevens Institute of Technology at the same place. He died at Paris, Aug. 8, 1868.

STEVENS, WILLIAM BACON (1815–1887), a bishop of the American Episcopal Church, was born at Bath, Maine, July 13, 1815. Having early lost his father, he was brought up in the residence of his grandparents in Boston. He belonged to the Congregational Church, and expected to enter its ministry, but on account of ill-health he left Phillips Academy, Andover, and took a sea-voyage around the globe, spending five months in the Sandwich Islands and five more in China. On his return he studied medicine at Savannah, Ga., but received his degree from Dartmouth College in 1837. While engaged in practice at Savannah he organized the Georgia Historical Society, and edited two volumes of its *Collections*. His health having been restored he took up the study of theology under Bishop Stephen Elliott, and was ordained in the Episcopal Church in 1843. He was then called to be professor of belles-lettres and moral philosophy in the University of Georgia, at Athens, and, having been appointed by the legislature State historian, he published his *History of Georgia* (2 vols., 1847–59), which was highly commended by Bancroft and Sparks. In 1848 he was chosen rector of St. Andrew's Church, Philadelphia, and, removing to that city, became noted as a pulpit orator. In 1861 he was chosen assistant bishop of Pennsylvania, and in 1865 succeeded Bishop Alonzo Potter in charge of the diocese. Under his episcopal direction the religious and benevolent work of the church was diligently prosecuted, and in a few years the diocese, originally coterminous with the State of Pennsylvania, had to be twice divided. Bishop Stevens retained Philadelphia and four adjoining counties, which still preserved for Pennsylvania its relative rank in numbers and influence among the American dioceses. His work was at times seriously interrupted by ill-health, and in 1886 he was obliged to ask for an assistant. He resumed his activity, however, and was engaged in performance of public duty until within a few weeks of his death. He died at Philadelphia, June 11, 1887. Besides the historical works noted, he published some charges, devotional treatises, and memorial discourses. For some years he had oversight of the American Episcopal churches on the Continent of Europe, and in 1885 he preached the sermon before the Pan-Anglican Council at Lambeth.

STEVENSON, ROBERT LOUIS, British author, was born at Edinburgh in 1845. He was grandson of the engineer Robert Stevenson, famous for his building of light-houses (for whom, see ENCYCLOPÆ-

DIA BRITANNICA). He was educated at the university of his native city, and from it obtained the degree of M. A. While still an undergraduate, he had started a college magazine. He travelled on the Continent of Europe and across the United States. His first book to attract attention was *Travels with a Donkey in the Cévennes*. But still more popular were his *Treasure Island*, *Kidnapped: a Story of the Rebellion of '45*, *The Dynamitards*, and others.

STEVENSON, WILLIAM FLEMING (1832–1886), Irish Presbyterian minister, was born at Strabane, Sept. 20, 1832. He graduated at the University of Glasgow and, after studying theology in Scotland and Germany, was licensed to preach in 1856. His first work was as city missionary in Belfast, and in 1860 he took charge of a newly formed Presbyterian church in Dublin. He was also busy in contributing to *Good Words* and other periodicals. In 1871 he was called to assist in directing the foreign mission work of the Irish Presbyterian General Assembly. In 1873 he attended the meeting of the Evangelical Alliance at New York, and in 1877 he travelled around the world in the interest of missions. In 1881 he was made moderator of the Irish General Assembly. He was a member of the senate of the Royal University, and was made chaplain to Lord Aberdeen, when viceroy of Ireland. He died at Rathgar, Dublin, Sept. 16, 1886. His published works are *Praying and Working* (1862); *Lives and Deeds Worth Knowing* (1870); *Hymns for Church and Home* (1873).

STEWART, CHARLES (1778–1849), rear-admiral, U. S. N., was born of Irish parents at Philadelphia, July 28, 1778. His father died two years later, leaving his widow, with four children, in straitened circumstances. Charles entered the merchant service as cabin boy at the age of 13, and rose to the command of an Indiaman before he was 20. In 1798 he entered the navy as lieutenant and served on board the frigate United States against the French privateers in West India waters. In 1800 he was appointed to command the schooner Experiment, and in these seas captured the French schooner Deux Amis and, soon after, the Diana, of 14 guns, retaking several American vessels which had been made prizes by the French. The same year he rescued 60 women and children who had been wrecked when escaping from the revolution in Santo Domingo, which service the Spanish governor of the island acknowledged in a letter of thanks to the President. In 1804, in command of the brig Siren, Stewart took part in the naval operations under Preble against Tripoli, co-operating with Decatur in the destruction of the Philadelphia, which had fallen into the hands of the Dey. In 1806 he was promoted to captain. From 1808 to 1812 he was employed in the merchant service, but re-entered the navy in the latter year on the outbreak of war with Great Britain. In the summer of 1813 he took command of the Constitution and sailed from Boston on a cruising expedition to the coasts of Guiana and the Windward Islands, capturing the British war-schooner Picton, of 14 guns, a letter-of-marque under her convoy, and several merchant vessels. In December, 1814, he set out on a second cruise on board the Constitution, then mounting 52 guns, with 470 men, and on Feb. 20, 1815, after an engagement of 50 minutes, captured the British war-ship Cyane, of 34 guns and 185 men, and the sloop of war Levant, of 21 guns and 156 men. The British loss was stated as 41; Stewart's was 3 killed and 12 wounded. A British fleet approached while he was lying at St. Jago, Cape de Verde, from which he adroitly escaped, carrying with him the Cyane; the Levant was, however, recaptured. For these services he received from Congress a vote of thanks, a sword, and a gold medal; from the legislature of Pennsylvania, a vote of thanks and a sword; and from New York, the freedom of the

city. From the public he received the flattering sobriquet of "Old Ironsides." From 1816 to 1820 he was on the Franklin, in command of the Mediterranean squadron, and from 1820 to 1824 of that of the Pacific, where he vindicated the rights of American commerce by compelling the annulment of a paper blockade. From 1830 to 1832 he was a commissioner of the navy, and, 1838 to 1841, commanded the Philadelphia navy-yard. In 1842 and 1843 he was in charge of the home squadron, and again of the Philadelphia navy-yard in 1844 and from 1854 till 1861. In 1862 he was made rear-admiral on the retired list. He died at Bordentown, N. J., Nov. 7, 1869, having been in the service 71 years and senior officer for 19. In 1835 his daughter, Delia Tudor, was married to John Henry Parnell of Avondale, County Wicklow, Ireland, by whom she is mother of Charles Stewart Parnell (*q. v.*).

STILES, EZRA (1727-1795), educator, was born at North Haven, Conn., Nov. 29, 1727. His father was pastor of the church at that place and published some religious treatises. The son graduated at Yale College in 1746, became a tutor there, and studied theology. After being licensed to preach he turned to the law, and was admitted to the bar in 1753. Three years later, however, he was ordained pastor of a church at Newport, R. I., but during the occupation of that city by the British he removed to Portsmouth, N. H. He was called to be president of Yale College in 1778, and held that position till his death, meantime discharging the duties of various professors. He died, May 12, 1795. He had a high reputation for learning of various kinds, from the ancient languages to modern science. He made some of the first electrical experiments in New England, and taught all the natural sciences. Besides some sermons, he published a *History of the Three Judges of Charles I.* (1794), and left incomplete an *Ecclesiastical History of New England*. His diary and other writings are preserved in Yale College library. His *Life* was written by his son-in-law, Dr. Abiel Holmes (1798) and Prof. J. L. Kingsley (1842).

STILLE, CHARLES JANEWAY, historian and educator, was born at Philadelphia, Sept. 23, 1819. He graduated at Yale College in 1839, and was admitted to the bar. During the war for the Union he was active in the cause of the U. S. Sanitary Commission (*q. v.*), and afterward wrote its history. He also obtained note by his pamphlet, *How a Free People Conduct a Long War* (1862), and some other publications. In 1866 he was appointed professor of history in the University of Pennsylvania (*q. v.*), and in 1868 was made provost of that institution. From his first connection with the university he endeavored to infuse a new spirit into it, advocating the enlargement of its courses of study, and especially promoting the scientific department. The result of these efforts is partly seen in the new buildings of the university. Dr. Stille retired from his position in 1880, and has since devoted himself to historical research, publishing *Studies in Mediæval History* (1881), and various monographs on American history.

His brother, ALFRED STILLE, physician, was born, Oct. 30, 1813. He graduated from the University of Pennsylvania in 1832, and from its medical department in 1836. He then studied medicine in Europe, and in 1839 became resident physician at the Pennsylvania Hospital. In 1854 he was made professor of the theory and practice of medicine in Pennsylvania Medical College, and held this position till 1859. In 1864 he was elected to a similar chair in the University of Pennsylvania, and held it for twenty years, then becoming professor emeritus. He has also lectured before various medical societies, and was president of the American Medical Association in 1871. He has published many professional treatises, including *Elements of General*

Pathology (1848); *Therapeutics and Materia Medica* (1860); and *Epidemic Meningitis* (1867). With J. M. Maisch he prepared the *National Dispensatory* (1879), and edited the second edition of *Medical Jurisprudence*, which had originally been prepared by his brother Dr. Morilton Stillé (1822-55) and Dr. Francis Wharton.

STILLWATER, a city of Minnesota, county seat of Washington Co., is on the west bank of St. Croix river, which here expands into a lake, 18 miles N. E. of St. Paul, with which it is connected by railroad. It contains a fine court-house, 2 national banks, 12 churches, a high school, a public library, a penitentiary, 1 daily and 3 weekly newspapers. It has also an iron foundry, flour- and saw-mills, and carries on a large trade in pine-lumber. Its population in 1880 was 9055.

STÖCKER, ADOLF, German clergyman, was born at Halberstadt, Dec. 11, 1835. He was educated in his native town and at the Universities of Halle and Berlin until 1857. Having been ordained in the United Evangelical Church, he became pastor at Seggerde in 1863. In the war of 1870 he was chaplain to a division of the German army, and in 1874 he was called to Berlin as court and cathedral preacher. He has published several sermons and addresses, but is chiefly noted as an advocate of Christian socialism and as a leader in the agitation against the increasing influence of the Jews in Germany.

STÖCKHARDT, JULIUS ADOLF (1809-1886), German chemist, was born, Jan. 4, 1809, at Röhrsdorf, Saxony. He was classically educated, graduated in natural science as pharmacist of first class in 1833, and received the degree of Ph. D. at the University of Leipsic in 1838. In 1834 he travelled in England, France, and Belgium, and he revisited the last two in 1843, to perfect his technical knowledge. In 1838 he taught at Dresden, and next at Chemnitz, and was appointed inspector of drugs. His lectures before the Chemnitz Agricultural Society began a popular movement, the first-fruit of which was the founding at Möckern, Saxony, in 1852, of an experiment station. The number of these institutions in Europe and America now exceeds one hundred. The movement has resulted in a wide diffusion of knowledge of chemical principles as applied to the soil. In 1848 he became the first occupant of the chair of agricultural chemistry in the Royal Academy of Tharand. He died there June 1, 1886. In periodical literature he was editor of *Polytechnisches Centralblatt* (1846-49); *Zeitschrift für deutsche Landwirthe* (1850-55); *Der Chemische Ackermann* (Leipsic, 1855-76). His other publications are, *Untersuchung der Zwickauer Steinkohle* (1840); *Erkennung und Anwendung der Gifffarbe* (1844); *Schule der Chemie* (1846), translated as *Principles of Chemistry*, New York; *Chemische Feldpredigten* (*Agricultural Chemistry*, Phila.); the last-named two works are translated into several languages. Stöckhardt ranks next to Liebig in aptness for popularizing science rather than in original research.

STOCKTON, a city of California, county seat of San Joaquin Co., is on Stockton Creek, a navigable branch of the San Joaquin river, which flows 3 miles westward. It is on the Central Pacific Railroad, 92 miles E. of San Francisco, and has also local railroads. It has a court-house, several banks, 15 churches, a convent, a high school and other schools, a theatre, 2 public libraries, 2 daily and 7 weekly newspapers, and the State asylum for the insane. Its supply of water is chiefly from artesian wells. It was settled in 1849, and in 1880 its population was 10,282.

STOCKTON, RICHARD (1730-1781), a signer of the Declaration of Independence, was born near

Princeton, N. J., Oct. 1, 1730. His great-grandfather came from England in 1670, and purchased a tract of 6400 acres, including the site of Princeton, the property largely remaining in the family. Richard was graduated at Princeton in 1748, and, after studying law in Newark, was admitted to the bar in 1754, where he acquired repute and a competent fortune. In 1766-67 he visited Great Britain, and while in Scotland prevailed on Dr. Witherspoon to accept the presidency of Princeton College. In 1768 he became a member of the executive council of the province, and in 1774 judge of the Supreme Court of New Jersey. In this same year he submitted to Lord Dartmouth "An Expedient for the Settlement of the American Disputes." On this failing to effect its purpose, he allied himself with the patriot party, and in 1776 was chosen a member of the Continental Congress that met in Philadelphia, where he was one of the signers of the Declaration of Independence. In September of this year he was chosen one of a committee to inspect the Northern army, and on Nov. 30 was seized by night in Monmouth, N. J., and committed to the common prison of New York, where he underwent treatment that seriously affected his health and, ultimately, conduced to his death. Meanwhile his library, one of the finest in the country, had been burned and his land laid waste, so that he was reduced to severe pecuniary straits. He died at Princeton, Feb. 28, 1781. In 1898 the State of New Jersey placed his statue in the Capitol at Washington. His wife, ANNIS BOUDINOT, was a poetess of no mean merit. One of her poems, addressed to Washington after the surrender of Yorktown, elicited from the patriot chief a courtly acknowledgment; another was sung by young ladies while strewing flowers on the path of the hero on his passage through Trenton on his way to his first inauguration at New York.

His son, RICHARD STOCKTON (1764-1828), senator, was born near Princeton, April 17, 1764, studied law in Newark, and was admitted to the bar in 1784. He rose rapidly to the head of the profession in the State; was a presidential elector in 1792 and 1801; United States senator 1796-99; and representative in Congress 1813-15, declining further candidacy. He received the degree of LL. D. from Queen's (now Rutgers) College in 1815, and from Union in 1816. He died near Princeton, March 7, 1828.

ROBERT FIELD STOCKTON (1795-1866), son of the preceding, commodore, was born in Princeton, Aug. 20, 1795. He left Princeton College before completing his course, and in 1811 entered the navy as a midshipman, at once distinguishing himself for gallantry, especially in the defence of Baltimore against the British, for which, in 1814, he was promoted to lieutenant. On the declaration of war with Algiers he sailed with the Decatur to the Mediterranean, but was transferred, as 1st lieutenant, to the Spitfire, in which he took part in the capture of the Algerine frigate Mahonda, and in 1815 headed the boarders in the capture of the corsair Esledio. In 1821 he went to Africa in command of the Alligator, and aided the Colonization Society (q. v.) in acquiring by purchase from native chiefs the territory now constituting the Republic of Liberia. While engaged in this service the Alligator was fired on by a Portuguese letter-of-marque, which mistook it for a pirate. An engagement of 20 minutes sufficed to capture the assailant, which, however, was subsequently returned to Portugal. By his capture of the French slaver Jeune Eugénie Lieutenant Stockton established the legality of seizing slavers under a foreign flag. In 1823-24 he was employed on the survey of the coast of the Southern States. From 1826 to 1838 he was on leave at Princeton, and took an active part in politics as a follower of Gen. Jackson. In 1838 he served as

flag-officer in the Mediterranean, and on his promotion to captain on Dec. 8 was recalled. In 1841 he was offered by Pres. Tyler a seat in the cabinet as secretary of the navy, but declined office. He was one of the first to advocate a steam navy, and prepared the plans for the steam sloop of war Princeton, which was built at Philadelphia, 1842-44, and was given command of it. On a trial-trip on the Potomac in the latter year one of her guns burst, causing the death of five persons, including the Secretaries of war and the navy. A court of inquiry entirely exonerated Captain Stockton. He next sailed to Texas as bearer to its government of the annexation resolutions. In the Mexican war he was commander-in-chief of the squadron on the Pacific, and in 1846, by proclamation, assumed command of all American forces on the coast, conquering California and establishing the authority of the United States. In 1847 he was relieved, and returned home overland, being received with honor by all parties. The New Jersey legislature gave him a vote of thanks and a reception. In 1850 he resigned from the navy, and in 1851 was elected to the U. S. senate, where he promoted the abolition of flogging in the navy. He resigned his seat in 1853, and retired to private life, dying at Princeton, Oct. 7, 1866.

His son, JOHN POTTER STOCKTON, senator and lawyer, was born in Princeton, Aug. 2, 1826. He was graduated at Princeton, 1843, studied law, and was admitted to the bar, 1850, and immediately attained a high position in his native State. He was appointed by its legislature a commissioner to simplify proceedings in the courts of law; in 1857 was sent as U. S. minister to Rome; in 1865 was chosen by a plurality vote to the U. S. senate, but this being challenged he was unseated by a vote of 23 to 21, March 27, 1866. He was re-elected in 1869, serving one term. In the Senate he advocated with effect the establishment of life-saving stations on the coast. In 1877 he was appointed attorney-general of New Jersey, and was re-elected in 1882 and 1887, in which office he has consistently sustained the system of railroad taxation. Ever since 1864 he has been delegate-at-large to all the Democratic national conventions. In 1882 Princeton conferred on him the degree of LL. D.

STODDARD, RICHARD HENRY, poet, was born at Hingham, Mass., in 1825. He was a contributor to the *Knickerbocker Magazine*, and published his first collection of poems, *Foot-Prints*, in 1849, and a second collection in 1851. After his marriage to Elizabeth D. Barstow, in 1852, he settled in New York, where he was employed in the custom-house. He has since been prominently identified with the literary life of the metropolis. In recent years his sight has been much impaired. Among his publications are *Songs of Summer* (1857); *Town and Country* (1857); *The King's Bell* (1863); *The Book of the East* (1871). He has also written some prose works and tales for the young, and edited various collections of English and American poetry. He excels as a lyric and imaginative poet and is a successful writer of blank verse.

STONE, CHARLES POMEROY, general, was born, Sept. 30, 1824, in Greenfield, Mass. He graduated at West Point in 1845, and became 2d lieutenant in the ordnance. In the Mexican war he served from Vera Cruz to the capture of the City of Mexico, and was brevetted in 1847 for gallant and meritorious conduct in the battles of Molino del Rey and Chapultepec. In 1848 he obtained leave of absence to visit Europe, with the object of improving in his profession. In 1851 he was ordered to California, where he constructed the Benicia arsenal, acting, at the same time, as chief of ordnance for the division of the Pacific. Resigning in 1856, he engaged in the banking business in San Francisco till appointed, next year, by the Mexican government, chief of a

scientific commission to survey and explore its lands in Sonora and Lower California. From this work he was called on Jan. 1, 1861, to become colonel and inspector-general of the militia of the District of Columbia. He was here engaged, under Gen. Winfield Scott, in disciplining volunteers, and on May 17 he was made brigadier-general of volunteers and put in charge of the defences of Washington. Under Gen. Patterson he led a brigade in the latter's Shenandoah campaign, and from August, 1861, till February, 1862, was in command, under McClellan, of the corps of observation of the Army of the Potomac. Having, on Oct. 20, 1861, been ordered to make a feint of crossing the Potomac at Ball's Bluff, as if with the view of attacking the enemy there, he, on his own authority, converted the feint into a real attack and was disastrously repulsed on the next morning. There was a popular outcry against the commander, which increased after Congress met in December. On Feb. 9, 1862, he was arrested and placed in confinement in Fort Lafayette, New York harbor, where he lay till Aug. 16th. He was then released, without any explanation. In May, 1863, he was ordered to duty in the Department of the Gulf, where he took part in the siege of Port Hudson and took part in receiving the surrender of the place, July 8, 1863. Selected by Gen. Banks as his chief of staff, he was present at the battles of Sabine Cross-roads and Pleasant Hill (April 8 and 9, 1864). On April 4, 1864, he was honorably mustered out as brigadier-general of volunteers, and on Sept. 13 resigned his commission as colonel of the 14th Infantry. In 1870 he entered the service of the Khedive of Egypt and was made chief of the general staff of the army. Subsequently he was made temporary chief of the cadastral survey, and was president of the Geographical Society. When the American officers were mustered out of the Egyptian service, in 1879, Stone alone remained, and held his position of chief of the staff till the insurrection of Arabi Pacha. In 1883 he resigned and returned to the United States, decorated with several orders conferred by Ismail Pacha. Since his return he has held the posts of engineer-in-chief for the Florida ship-canal and transit company, and to the committee for the erection in New York harbor of Bartholdi's statue of Liberty Enlightening the World.

STONE, WILLIAM LEETE (1792-1844), author, was born, April 20, 1792, at New Paltz, N. Y., his father having been a soldier in the Revolutionary war. He spent part of his youth on his father's farm at Sodus, N. Y., which was then in a wilderness, and there met with adventures and gained experiences he afterward embodied in his border tales. At the age of 17 he became a printer, and in 1813 he was editor of the *Herkimer American*, on which Thurlow Weed worked as a journeyman. He subsequently edited political papers in Hudson, Albany, and Hartford, besides conducting at Hudson a literary periodical entitled *The Lounger*, and at Hartford, in conjunction with J. M. Wainwright (afterward bishop) and Samuel G. Goodrich ("Peter Parley"), *The Knights of the Round Table*. From 1821 till his death he was one of the proprietors and editors of the *New York Commercial Advertiser*, employing its columns to advocate, among other objects, the cause of abolition of slavery and that of compulsory education. Soon after the Morgan tragedy he, although himself a freemason, addressed a series of letters to John Quincy Adams (afterward collected and published at New York, 1832), urging the abandonment of Freemasonry because it had outlived its usefulness. In 1841 he was sent by Pres. Harrison as U. S. minister to the Hague, but was recalled the same year by Pres. Tyler. He was chosen, in 1844, the first superintendent of the public schools of New York City, and in this capacity had a controversy

with Archbishop Hughes in regard to the use of the Bible in schools. His influence for good was felt in the city in many directions. He especially interested himself in the institution for the deaf and dumb and the society for the reformation of juvenile criminals. Mr. Stone died at Saratoga Springs, Aug. 15, 1844. He was a prolific author, especially in the department of local history. Among his publications were *Life of Maria Monk* (1836); *Letters on Animal Magnetism* (1837); *Life of Joseph Brant* (2 vols., 1838; later edition by his son, W. L. Stone, 1865); *Border Wars of the American Revolution* (2 vols., 1839); *Poetry and History of Wyoming* (1841; new ed., 1864); *Life of Red Jacket* (1835; new edition, with a life of the author, by W. L. Stone, Jr., 1866); and *Life of Uncas and Miantonomoh* (1842).

STONEMAN, GEORGE, general, was born, Aug. 8, 1822, at Busti, Chautauqua county, N. Y. In 1846 he graduated at West Point, and was assigned to the First Dragoons. In 1847 he went, as quartermaster of the Mormon battalion, to California, and remained in active service on the Pacific coast till 1857, when he was promoted captain and ordered to Texas. While in command of Fort Brown, in that State, his superior officer, Gen. D. E. Twiggs (who joined the secessionists, making over to them his army together with the government stores), ordered him to surrender the national property under his charge. This order Stoneman refused to obey, then evacuated the fort and proceeded by sea to New York. In May, 1861, he was advanced to major, and in August to brigadier-general and chief of cavalry of the Army of the Potomac, commanding this arm during McClellan's Peninsular campaign in 1862. After the capitulation of Yorktown his corps overtook the Confederate force, and so brought on the battle of Williamsburg. After the second Bull Run fight, he got the command of Gen. Phil. Kearney's division, and in November, 1862, was made major-general of volunteers, and put in charge of the Third Army Corps in succession to Gen. S. P. Heintzelman, leading it at Fredericksburg, Dec. 13th. In April and May, 1863, he led a cavalry corps in the raid toward Richmond, and from January till April, 1864, was in command of the Twenty-third Corps. When Gen. Grant reorganized the armies operating before Richmond, Gen. Stoneman was assigned to a cavalry corps in the Department of the Ohio, and served under Sherman in the Atlantic campaign of 1864, taking an active part in the operations; among others, conducting a raid for the capture of Macon and Andersonville. Being captured on July 31 at Clinton, he was kept a prisoner till Oct. 27. During February and March, 1865 he had command of the district of Eastern Tennessee, and in March and April was leader of an expedition to Asheville, N. C., being engaged at Wytheville, in the capture of Salisbury, and at Asheville. In June, 1866, he was made colonel of the 21st Infantry, and was brevetted, in succession, colonel, brigadier general, and major-general. In August, 1871, he resigned from the army, and took up his residence in California, of which State he was governor from 1883 till 1887.

STONE RIVER, OR MURFREESBORO', BATTLE OF. When Gen. Bragg, on crossing the Cumberland River after the battle of Perryville (Oct. 8, 1862), perceived himself no longer pursued, he halted his forces, numbering some 40,000, at Murfreesboro' on the Stone River and the Nashville and Chattanooga Railway, about 30 miles S. E. of Nashville. On Oct. 27 Gen. W. S. Rosecrans was transferred to the command of the Union Army of the Ohio or Cumberland, which at this time lay around Bowling Green and Glasgow in Kentucky. On his arriving, on Oct. 30, he found the force in a sadly demoralized condition, and reduced in numbers from 100,000 to 65,000. With the exception of the city of Nash-

ville—weakly garrisoned and poorly supplied—it had nothing to show for its nine months' campaign. The district was scoured by Confederate cavalry under Capt. J. H. Morgan and Col. N. B. Forrest, who rendered it most difficult to keep up communications with the Union depot of supplies at Louisville. After reorganizing the army and replenishing its ammunition, he took immediate steps to avert the danger with which Bragg's proximity menaced Nashville. By Nov. 7 he had the main part of his forces concentrated in front of that city, southward, and covering the roads leading in that direction. To insure the maintenance of communication with Louisville the main part of his centre division was stationed at Gallatin. For about six weeks he lay thus, employed in collecting supplies of various kinds preparatory to a movement upon Bragg. During this period his men were engaged in frequent skirmishing conflicts with the enemy, among which was the surprise of the Union Col. Moore and capture of 1500 men by Morgan's rough-riders at Harts-ville on Dec. 1st. But the hour for more important movements was at hand. Bragg had no idea that Rosecrans would undertake a winter campaign and had sent away a large portion of his force—one section (cavalry) into West Tennessee, to annoy Grant; the other into Kentucky, to break up the railroad forming Rosecrans' sole means of communication with his depots at Louisville. The latter commander judged that the opportunity was not to be let slip and at once took action.

At dawn of Dec. 26 the Union army moved southward: McCook, with 3 divisions (16,000 men), along the Nolensville pike toward Triune; Thomas, with two divisions, Negley's and Rosecrans' (13,500), by the pike on his right to fall in by cross-roads to Nolensville; and Crittenden, with 3 divisions (13,300), on the Murfreesboro' pike toward Lavergne. The plan given out was that McCook should attack the Confederate general, Hardee, who was reported lying with a large force at Triune, 7 miles south of Nolensville, and, in the event of Hardee's having to retreat, that Crittenden should assail him at Stewart's Creek, while Thomas was to come in on his left flank. These movements were to be covered by Brig.-Gen. D. S. Stanley, chief of cavalry. McCook (skirmishing all the way) reached Nolensville in the evening and rested there, with Thomas on his right, who closed Negley's division on Nolensville. Crittenden, with the left, reposed near Lavergne. Late at night Rosecrans, who had left Nashville at noon, arrived at McCook's headquarters.

On McCook's arrival before Triune next day (27th) he found that Hardee had retired, and he rested there for the night. Crittenden the same day reached Stewart's Creek. Next day was Sunday, and a day of almost general rest. On the morning of Monday (29th) McCook pushed on from Triune to Wilkinson's Cross, 6 miles from Murfreesboro', while Crittenden, moving on the Murfreesboro' pike, skirmished forward to the West Fork of Stone River, within a short distance of Murfreesboro'. In the afternoon Palmer signalled headquarters at Lavergne (erroneously) that the Confederates were evacuating the village, and Harker of Crittenden's was ordered to cross the stream and occupy it. His brigade on crossing found Breckenridge in strong force in front, and Crittenden wisely recalled him. Next morning McCook moved close up to Stone River, a little west of the town, and before evening nearly the whole Union force stood in an irregular line, more than three miles in length, in front of the Confederates, who held a strong position before Murfreesboro'. During the night of the 30th both armies prepared for battle. Crittenden was on the Union left, resting on Stone River; Thomas held the centre; McCook stood on the right. Bragg disposed his forces—the

right under Breckenridge in the rear of Stone River; Polk in the centre, and Hardee on the left, both in front of the stream. At 9 p. m. the Federal commanders met at headquarters and Rosecrans explained his plan of battle. The left and centre were to be thrown heavily on Breckenridge at daybreak, crush him, wheel rapidly, and attack the front and flank of the Confederate centre, and then, sweeping through Murfreesboro', gain the rear of the centre and left, cut off their line of retreat, and so destroy the army in detail.

Before sunrise of the 31st Van Cleve's division of Crittenden's crossed the river, and Wood was ready to follow him in support. Meanwhile a counter-movement of the Confederates entirely deranged Rosecrans' scheme. Bragg had decided to attack the Union right at dawn, and with this view had massed his troops on his left under Hardee in front of McCook. In the dim light of dawn these emerged on a sudden from the close woods. Cleburne led with four brigades and charged McCook's extreme right before Van Cleve had moved. Cheatham's and McCown's divisions struck nearer the centre, and, despite a storm of missiles, fell heavily on the brigades of Willich and Kirk and forced them back in confusion. Kirk was seriously wounded; Willich was taken captive; Edgarton's battery and part of Goldspeer's were captured and turned on the fugitives; a large number of prisoners were taken. Following up this success, the victors fell on McCook's left, composed of the divisions of Sheridan and J. C. Davis, striking them on the left flank. After a severe struggle, especially on the part of Sheridan, these also gave way and fell back almost to the Nashville pike. In this onset Houghtailing's battery and part of Brash's were lost.

It was now 11 o'clock. The Union right wing, comprising one-third of the army, was completely broken up, and the Confederate cavalry were in Rosecrans' rear. It seemed as if the day were lost. The Union troops had been driven from nearly half the ground they held at dawn, and they had lost many hundreds of men. The brunt of the battle fell now on Thomas in the centre, who had been reinforced by Rousseau's reserve division. The enemy pressed toward his rear till they reached a position whence they poured a storm of cross-fire on Negley and Rousseau. This compelled Thomas to withdraw from the cedar-wood he occupied and form line in the open ground between the woods and the Nashville pike. This position he held firmly, and enabled Rosecrans to readjust his line in accordance with the position of affairs. The fight was not yet over. Palmer's division, on the right of the Union left wing, was next assailed in front and rear. His right brigade, under Craft, was beaten back, and the assailants fell on the second brigade under W. B. Hazen. This broken, the Confederate victory was complete. Hazen felt that on him depended the issue of the battle, and, at a terrible sacrifice, held his ground till Rosecrans was able to form his new line. His brigade, by staying the tide of Confederate victory, saved the day. But the struggle was not over. Bragg's entire force, excepting a part of Breckenridge's across the river, now pressed on to break the newly formed Union line. Wood, though severely wounded, with Van Cleve, fought the Confederate left under Breckenridge and repulsed his charges till darkness put an end to the conflict, leaving the Union troops, to use Rosecrans' own words in his report, "masters of the original ground on their left, and their new line advantageously posted, with open ground in front, swept at all points by their artillery."

Rosecrans' loss in men and guns had been heavy, but he was not discouraged. Bragg had sent a despatch to Richmond stating that after ten hours

fighting he "had driven the enemy from every position but his extreme left, held by Hazen, and had as trophies 4000 prisoners, 2 brigadier-generals, 31 guns, and 200 wagons and teams." What, then, must have been his astonishment to see his antagonist standing next morning, on advantageous ground and with undiminished confidence, in order of battle? This day (Jan. 1) little was attempted by either of the exhausted armies beyond skirmishing and artillery firing, and preparing for a renewal of the struggle. Van Cleve's division had during the night been thrown across Stone River and taken possession of a height commanding the upper ford. Nor had Bragg been idle during the same time, but had planted four batteries to sweep the Union lines, and with these he opened a terrific fire at 8 A. M. This was, however, quickly silenced by Bradley's guns and those of Walker's and Sheridan's divisions. There was now a lull till 3 P. M., but the Confederates were massing along Beatty's front and threatening danger there.

Rosecrans, adhering to his original plan of turning Bragg's right and capturing Murfreesboro', had strengthened Van Cleve's division by one of Palmer's brigades. While he was engaged in examining the line it was suddenly assailed by Breckenridge's entire corps with cavalry and artillery, aided by heavy enfilading fire from Gen. Leonidas Polk's artillery in the centre. The Union troops were rapidly driven in confusion across the river, closely followed by Bragg's entire right wing in three lines of battle, which came sweeping down the slopes to the edge of the stream.

But in the meantime Crittenden's artillery had been massed on the rising ground on the opposite side, to enfilade the enemy with 58 heavy guns, and these opened with fatal effect, mowing down the pursuers in lanes. A fierce battle ensued. Both sides massed their batteries; both felt that the decisive moment had come. "For a time," says an eloquent writer to whom we acknowledge our obligations, "it seemed as if mutual annihilation were to be the result." Finally Miller, and Stanley with his cavalry, charged simultaneously and drove the Confederates rapidly before them. This charge decided the day. "In 40 minutes," says Rosecrans, "the Confederates lost 2000 men, and their entire line fell back leaving 400 captive." The Battle of Murfreesboro' was over.

The 3d was occupied by Rosecrans in making preparations to follow up his victory. During the night Bragg retreated through the village in the direction of Chattanooga, leaving 2000 sick and wounded in his hospitals. The next day was Sunday, and all remained quiet. On the morning of Monday (Jan. 5th) the Confederate rear-guard was driven by Thomas 6 or 7 miles on the Manchester road and the village definitely occupied.

The loss on both sides had been heavy. That of the Union army was 1533 killed, 7245 wounded, and 3000 prisoners. Bragg claimed to have taken 6273 prisoners. His own loss he acknowledged to be 10,000, of whom 9000 were killed and wounded.

(J. H.)

STONES, BUILDING. The ordinary building materials may be divided into two classes, natural and artificial, the former comprising wood and stone, the latter brick, iron, artificial stone, etc. Of these stone is ordinarily the most expensive, but is preferred for all buildings intended to be handsome and imposing, from its beauty of texture and color and the appearance of massive solidity which it is capable of giving. It has its defects, however, many building stones being deficient in durability when exposed to the atmosphere. Some rapidly decay under the influence of the weather, particularly in damp, frosty climates, while some are seriously af-

ected by the sulphurous and other acid emanations of large cities. London is particularly destructive to building stones from these causes—materials rapidly disintegrating there which are very durable in drier and purer atmospheres. The building stones of the United States yet await thorough exploration. The first effort to collect and display the wealth and variety of these products in the several States was made at the Centennial Exhibition of 1876, on which occasion a highly useful and instructive collection was displayed. More recently the National Museum at Washington has engaged in this desirable enterprise, and has now a large and handsome cabinet of the various building stones of the country, cut into 4-inch cubes.

Building stones may be broadly divided into three classes: First, the diversified series known under the general name of granite (named in government publications crystalline silicious rocks); second, the limestones and marbles; third, the sandstones. A fourth division, of minor importance in building, includes the slates. These various rocks are obtained and prepared for market by several processes, adapted to their special characters. For the harder rocks explosives are generally used, the rough masses obtained by blasting being afterward chiselled, sawed, or otherwise worked into shape. In other cases the rocks are got out by channelling and wedging, where natural lines of cleavage render this available, while the more fragile and valuable marbles are sawn out in the quarries, so as to avoid splitting the brittle rock by the use of the blast.

Granite may be defined as a crystalline, unstratified rock, composed usually of various combinations of mica, quartz, and felspar, and, as used in building, ordinarily susceptible of a fine polish. It is whitish or grayish in hue, or mottled with a flesh-red, but is sometimes quite dark. Its expensiveness prevents its being often used for private edifices, though it is generally used in large public buildings, and is coming more and more into employment for banks and other large commercial edifices. The employment of polished granite is rapidly extending, both for columns and other ornamental additions to buildings, and for cemetery purposes, where its durability makes it much superior to marble. The coarser kinds of granite are often used for street pavements where the traffic is heavy.

Granitic building stones are very widely distributed throughout the United States, though up to the present time New England has been the most important centre of the granite-quarrying industry. The granites of that region are, taken as a whole, the finest yet developed in the country, yielding several varieties of hardness, texture, and color, many of them being very beautiful and of unusual solidity. Nearly all the massive government buildings on the Atlantic seaboard, and many of the great public buildings in Washington are constructed of New England granite, from the Quincy and other quarries.

Good building granite occurs in Virginia, North and South Carolina, Georgia, and Tennessee, while in the valley of the Colorado, Texas, is an extensive deposit closely similar to the red sienite of Egypt. The State capitol at Austin is built of this stone. In the Rocky Mountain region granite suitable for building purposes occurs abundantly, existing in great quantities in Montana and Wyoming, and less extensively in Dakota. In Colorado extensive deposits have been opened, some containing a red crystalline rock susceptible of high polish, and suitable for fine ornamental work. Other quarries yield a cream-colored stone that polishes well. In addition to the granites may be named a fine pink-colored lava, which has been largely used as a building stone in Denver. Granitic rocks are abundant on the Pacific slope, the Sierra Nevada being composed of this material

throughout. Much of this stone has been used in San Francisco for public buildings. In the Penryn quarry, near Sacramento, the granite splits so evenly that blocks 100 feet long and of almost any thickness can be readily obtained. The colors are blue, black, gray, and other varieties of hue. Oregon and Washington possess granitic building stones in equal abundance.

In close connection with the granites may be named the green serpentines, which have been used to a considerable extent in Philadelphia buildings, being obtained from quarries in the vicinity of that city. The most imposing structures in this material are the buildings of the University of Pennsylvania. In western North Carolina there is a very large deposit of serpentine, or verd antique, which is sold under the name of green marble, polishes finely, and is much used for interior decoration. This is the only extensive deposit of this stone in the Union.

The limestones suitable for building purposes comprise three classes, common limestone, gypsum, and marble, the latter varying from coarse grades, which shade into limestone, to the finest-grained marbles. Of coarse marbles the most extensive deposit yet opened lies in Westchester county, N. Y., just north of the city. This has yielded nearly all the building marble used in New York City—the university, the Roman Catholic cathedral, and other imposing buildings being constructed of it. At Lockport exist extensive beds of a compact, soft, and easily worked grayish limestone, which hardens when exposed to the air. It is a handsome stone and has been largely used, the Lenox Library building, New York, being an instance.

North Carolina comes next to New York in the possession of extensive beds of building limestone. These occur in the mountain region of the west, while on the coast "shell limestones," suitable for building purposes, abound. East Tennessee possesses an abundance of oolitic limestone, characterized by minute round grains. This is very white, of excellent quality, works easily, and wears well. In the centre of the State are limestones nearly as hard as marble, of which the State capitol at Nashville has been built. West of the Mississippi extensive beds of limestone suitable for building occur in Missouri, Iowa, Kansas, and Nebraska, while in Iowa is a bed of solid gypsum which extends for 5 miles along the Des Moines river, and has been quarried and used for building. Montana, Wyoming, and Colorado are similarly well supplied, the Jefferson Company's quarries in the latter State being practically inexhaustible. On the Pacific slope limestones exist abundantly, but not of quality well suited for building purposes.

Marbles suitable for building are quite as widely distributed. The finest quality of American marble yet discovered is that of Vermont, being a portion of a continuous belt which extends from the coarse marbles of Westchester county, N. Y., across Vermont into Canada. The finest grades occur within 30 miles north and south of Rutland, Vt., the marbles here being of fine texture and pure white color. The veins of the finer material are nowhere very large, and it being more liable, with greater purity, to crack and splinter in quarrying, it is now got out by sawing instead of blasting. Ingenious machines drive peculiarly shaped saws, often with black diamond-pointed teeth, that cut channels into the rock. The deposits are practically inexhaustible, the marble being delicate in texture, some white enough for statuary, and all polishing finely. It is largely employed for furniture and interior decorations.

The southern Alleghanies possess vast deposits of marble, of fine texture and almost every shade of color; western North Carolina having beds of white, pink, black, gray, drab, and mottled, all susceptible

of a fine polish. Opposite these, in eastern Tennessee, are extensive beds of very handsome marbles, often beautifully variegated in color. These have been used extensively for interior finish in expensive private dwellings, and largely for steps and staircase wainscoting in hotels and other large public buildings. The colored Tennessee marbles have been used in the interior decoration of the Capitol at Washington, and in the governor's room of the Albany capitol building.

In Georgia exists much the largest bed of marble yet discovered in the Union. This marble is of uniformly fine texture, the color varying from white to variegated, some of the latter varieties being of great beauty. The marble area of North Carolina, Tennessee, and Georgia is greatly the most extensive in the Union, and its material the most diversified in character. In Iowa is a peculiar deposit known as coral marble, one of its constituents being a fossil coral or sponge, which shows itself in delicate tracings on the marble when polished. It is greatly varied in hue, the foundation color being mostly gray or drab, and the beds are practically inexhaustible.

Missouri is well provided with excellent marbles, one variety known as onyx marble being extensively used for mantels, fine furniture, etc. Montana, Wyoming, and Colorado are well supplied, while Oregon and Washington have rich deposits, as yet but little developed. Undeveloped beds also exist in New Mexico and Arizona.

Yet more important than the granites and limestones for building purposes are the sandstones, which are very largely employed in the fronts of private residences. When of good quality these stones will resist the effects of heat and cold, dryness and moisture. They are used ordinarily, on account of their cost, as a sort of veneer for house-fronts, being applied in thin slabs backed up with brick. Sandstones differ very considerably in constitution, some being silicious, some granitic, others argillaceous, etc. They differ as greatly in degree of compactness and in color, the principal shades being brown, drab, and bluish. The sandstones are the most widely and generally diffused and most diverse in texture, compactness, and color of all building stones. They usually occur in deposits of moderate extent, but so numerous and scattered as to be everywhere available. East of the Alleghanies the two most important deposits are those in the valley of the Connecticut river, and near Belleville, N. Y. These beds are of immense extent, and have supplied building stones to the adjacent cities and villages for more than one-third of a century. In Ulster county, N. Y., are extensive beds of a very hard blue-stone, which is much used for steps, sills, etc., and at Potsdam a deposit of very hard and durable stone, of reddish color with veins of gray.

The Southern Atlantic States have numerous small deposits of building sandstones, while in eastern Tennessee they occur largely. The States bordering the Mississippi and Ohio are very well provided, and the same is the case with the Rocky Mountain and the Pacific slope region. The colors vary greatly, there being shades of drab and blue, blue with gray tint, pure gray, greenish-gray, white, red, and quite dark. Vast quantities of these stones are used in building.

The slate quarries of the United States chiefly exist in Pennsylvania, New York, Vermont, and Maine. The first named of these States yields more than all the others combined, its largest quarries being on the Lehigh river in the vicinity of Allentown. This slate is of fine texture, and is well adapted for roofing and other uses. The New York and Vermont deposits are continuous with each other. Their slates are of excellent quality and are employed largely to imitate variegated marbles, be-

ing, when thus treated, extensively used for wash-stands, mantels, etc. In the South, Maryland, Virginia, and Georgia have large beds of slate suitable for building purposes.

The statistics of annual production of building stones in the United States, as given in the Census report for 1880, are as follows:

	Number of quarries.	Product (cubic feet).	Product (value).
Marble and limestone	616	65,523,965	\$6,356,681
Sandstone.....	502	24,776,930	4,780,391
Crystalline silicious rocks.....	313	20,506,568	5,188,098
Slate.....	94	4,572,670	1,529,985
Total.....	1,525	115,380,133	\$18,356,055

Of sandstone-producing States Ohio stands at the head, yielding 33 per cent. of the entire product. Pennsylvania yields 25, New York 12, New Jersey 8, and the other States in rapidly diminishing ratio. Illinois, Iowa, and Pennsylvania are the leading States in quantity of limestone and marble produced; while of the granites, Massachusetts yields 25 of the total product, Connecticut and Pennsylvania 14 each. Of the slates, as we have already said, Pennsylvania is the principal producer. The above ratio of State production, however, is destined to greatly change in the coming years. Building stones of good repute have been carried long distances, though equally good stone, without reputation, lay in the immediate vicinity of the builder. The development of the resources of the country will change all this, and the several States come more and more to depend on their own deposits for home use. (C. M.)

STONES, PRECIOUS. Up to the present time the territory of the United States has by no means proved prolific in the more valuable gems, the precious stones which it possesses in any abundance being of the less esteemed kinds. And though it is quite within the limits of possibility that important deposits may yet be discovered, the probability is against it, so far as the most highly valued gems are concerned. Of precious stones within the United States over thirty varieties are enumerated, but of these none of great money-value have been discovered. In 1884 the sale of native stones brought but \$28,650, while that of foreign importations reached \$8,712,315. In 1886 the value of native stones sold was \$79,056. So far there has been no persistent search for precious stones in this country, those found being generally discovered in the process of mining for metals and useful minerals. Systematic mining for precious stones is reported from only two places: Mount Mica, Paris, Maine, which in 1886 yielded \$5,000 worth of tourmalines (cut value); and Stony Point, N. C., where in that year nine emeralds were found, valued at over \$3,000, the value of the total find being about \$4,000.

Diamonds are found in the United States in very limited quantities and of small size. They are seldom of the first water. They have been picked up in widely separated localities, but nowhere in sufficient abundance to warrant extended research. Many of the claimed diamonds, indeed, have proved on testing to be minerals of much less value. They are found in gravel-beds and alluvial soil, no diamond-bearing matrix having been discovered. The find of 1884 was valued at \$800 only, and in it the most beautiful stone was worth but \$100, the others being generally colored. Itacolumite, or "flexible sandstone," which is looked upon as a matrix of the diamond, occurs in the Carolinas and Georgia, and many small stones have been found in its vicinity. The largest native diamond yet found was dug up in 1884 by a laborer at Manchester, Va. Its original

weight was 23½ carats, but cutting reduced it to 11½ carats. It was held at an extravagant value, and \$1500 expended on its cutting, yet it is not considered by experts as worth more than \$300 or \$400, it being off-colored and imperfect. Diamonds have been found in North Carolina, Georgia, Indiana, Oregon, and other States; also in the gravels or gold-washings of California and Nevada, but there is no clew to their place of origin. Of late years there have been observed in Kentucky and Tennessee deposits of peridotite in association with carbonaceous shales. This is exactly the condition existing at the Kimberley diamond mines, South Africa, and several geologists are of the opinion that the American peridotite may yet yield diamonds. But it has not yet done so, and the promise is not good.

Emeralds and beryls—stones which are similar in composition but differ in their coloring substance—have been found in small quantities. They are most abundant in North Carolina, but have also been found in Maine, Massachusetts, Connecticut, and Pennsylvania. Many beryls, yellow, green, and white in color, have been picked up in recent years in Litchfield county, Conn. The 1886 find of that locality, when cut, brought \$5,000. An interesting and valuable stone, allied to the emerald, was discovered in 1881 in Alexander county, N. C., as yet its only known locality. It is the only gem peculiar to the United States, and has been named Hiddenite, from W. E. Hidden, its discoverer. While, like emerald, a silicate of alumina, it differs in having lithia for its base. It occurs in slender crystals, resembling emerald only in color, and is found in nests or pockets, often associated with emerald and beryl. Its rarity and beauty have caused it to be greatly in demand, as yet largely for cabinet purposes.

Sapphires and rubies have been found in New Jersey and North Carolina. Macon county, of the latter State, has yielded them of various shades of color, blue, red, yellow, and colorless. In 1872 the Jenks mine, near Franklin, N. C., yielded a sapphire crystal, of 312 lbs. weight, which is now in the Amherst College mineral cabinet. In the west they are found in New Mexico, Colorado, Arizona, and Montana. Mount Helena, Montana, is the richest locality for sapphires in the United States. Topazes are found in Maine, New Mexico, Colorado, Utah, and Arizona. Pike's Peak, Colorado, has yielded some fine light-blue specimens, considered equal to those of the same size from Siberia. The Utah specimens are small, and generally of a limpid white color. Beautiful fire opals have been found in Georgia and North Carolina, but none possessed of opaline iridescence. Coarser grades occur in Lebanon county, Pa. In many places of the West opals occur with some play of color. Garnets are widely distributed, and crystals suitable for gems or watch-jewels abound in Colorado. Agates are found in many places along the Connecticut river, in southeastern Pennsylvania, and in North Carolina. They abound around Lake Superior and in the upper Mississippi region, while the Rocky Mountains and California yield beautiful specimens. The favorite variety known as moss-agate is found in Pennsylvania and North Carolina, and is abundant in Humboldt county, Nevada.

Amethysts occur in many localities in New England, in Delaware county, Pa., in Georgia, and in many places west. The Lake Superior variety is coated like the moss-agate. In Yellowstone Park they are found as a beautiful lining to the interior of hollow, petrified, or silicified trees. In color they are usually of light purple bordering on pink, and as gems are of little value. Tourmaline is found in Maine, New York, and Pennsylvania. The richest finds are in the Maine locality above-mentioned, the crystals being usually colorless, but

often of varying shades of pink, blue, yellow, and green. The two largest found in 1886 were of a rich grass-green color, and weighed respectively 34½ and 27¼ carats.

The stone known as serpentine has a translucent variety of a rich, oil-green color, varying from dark to pale. This is called precious serpentine and is used for ornaments. It is found from Maine to Maryland, and abounds in North Carolina, but not of fine quality. The finest grades come from near Newburyport, Mass. Malachite, suitable for ornament, occurs in very small quantities, though the Copper Queen mine, of Arizona, has yielded this mineral in large masses. Turquoise has been found of late years in New York, Arizona, and Nevada. It is not highly valued as a gem. The same may be said of jasper, which is found in many localities. North Carolina yields it of the texture known as cat's-eye. Jade has been obtained from the Indians of Alaska, but its locality is not known.

Chalcedony is obtained, of a pink color, from near Cisco, Utah. It takes a fine polish, but has been little introduced as yet. Jet, a variety of lignite or mineral coal, of value for mourning ornaments, is found abundantly in the California lignites. Amazon stone, a green felspar from Pike's Peak, is used slightly as a gem. Obsidian occurs largely in Yellowstone Park. Some of it is beautifully colored, and it may yet prove very useful in the ornamental arts. Jasperized, or so-called petrified wood, also abounds in the same locality and in Arizona. In this the wood-tissue has been replaced by silica. It polishes well, and is sold as an ornamental stone.

Of other minerals used for gems may be mentioned sunstone and moonstone, found only in Delaware county, Pa., and near Orange Court-House, Va.; spinel, occasionally found of fine quality; aquamarine, from several localities; phenakite, found at Pike's Peak, of fair size and fine quality; rock crystal (quartz), of which limpid specimens are often cut for gems; smoky quartz, which is cut as a gem to a considerable extent; and gold quartz, which, when clear and well penetrated by gold, makes a handsome stone. There are many other minerals which are occasionally cut and used as ornamental stones, but the above-named are the most important. (C. M.)

STORER, BELLAMY (1798-1875), jurist, was born at Portland, Maine, March 9, 1798. He graduated at Bowdoin College, studied law in Cincinnati, and was admitted to its bar in 1817. As editor of the *Crisis*, a Federal party-organ, he advocated in 1824 the election of John Quincy Adams as President. In 1835-37 he was a representative in Congress, and in 1844 a presidential elector in favor of Henry Clay. He occupied for many years a chair in the law school of Cincinnati, and was for 14 years a judge of the supreme court of Ohio. His religious feelings were warm. In his youth he was a leader in a band of young men who, under the name of "flying artillery," went from place to place promoting revivals. In 1821 his *alma mater* conferred on him the degree of LL. D. He died at Cincinnati, June 1, 1875, holding at the time the office of vice-president of the Evangelical Alliance.

His brother, DAVID HUMPHREYS STORER, physician, was born at Portland, March 26, 1804, and graduated at Bowdoin College in 1822. In 1825 he received the degree of M. D. from Harvard, and forthwith commenced practice in Boston, where he originated the Tremont Medical School. In 1854 he was appointed professor of obstetrics and medical jurisprudence in the Harvard Medical School, and was subsequently dean of that school. In 1876 the degree of LL. D. was conferred on him by Bowdoin. Dr. Storer for several years was physician to the Massachusetts General Hospital, he had charge of the

departments of zoology and herpetology in the Massachusetts State survey, and in 1866 was president of the American Medical Association. Among his productions are, *Synopsis of the Fishes of North America* (Cambridge, 1846); *History of the Fishes of Massachusetts* (Boston, 1853-67).

His son, HORATIO ROBINSON STORER, surgeon, was born in Boston, Feb. 27, 1830. He graduated at Harvard, 1850, where he devoted himself mainly to the natural sciences. Thereafter he studied medicine, receiving his degree in 1853. He spent the next two years in the great schools of Europe, acting for a year as private assistant to Sir James Y. Simpson, of Edinburgh. In 1855 he began practice in Boston, taking for his specialty midwifery and the diseases of women. From 1865 to 1869 he occupied the chair of obstetrics and medical jurisprudence in Berkshire Medical College. To qualify himself more perfectly for teaching medical jurisprudence, he returned to Harvard to attend its law school, and graduated from it in 1868. His lectures to medical students on the diseases of women were attended by physicians from all parts of the country. In 1872 he returned to Europe, spending five years there, mainly in Southern Italy, in the study of the fevers of that district. On his return to the United States he settled at Newport, R. I., where he still resides. Dr. Storer was instrumental in founding the Boston Gynecological Society, of which he was for some time president, acting also as editor of its journal. In 1865 he was secretary and prize-essayist of the American Medical Association, and its vice-president in 1866. He has been an exceptionally prolific writer on medical subjects, both in professional journals and in book-form. In the latter shape he has published *Why not? A Book for Every Woman*, which received the gold medal of the American Medical Association (Boston, 1866); *Is it I? A Book for Every Man* (1867); in conjunction with F. F. Heard, *Criminal Abortion; its Nature, its Evidence, and its Law* (1868); *On Nurses and Nursing*, (1868); and *Southern Italy as a Health Station* (1875).

His brother, FRANCIS HUMPHREYS STORER, born in Boston, March 27, 1832, studied also in Harvard Scientific School, devoting himself specially to chemistry under Prof. Josiah P. Cooke. In 1853 he was appointed chemist to the Pacific exploring expedition, and on his return completed his scientific course at Harvard, and graduated, 1855. After further study, in Europe, he devoted himself to teaching chemistry and to the practice of his profession as an analytical chemist, in which latter capacity he held several appointments. In 1870 he was appointed professor of agricultural chemistry in Harvard, a position he still holds, while he is, at the same time, dean of the Bussey Institution. He has been a constant contributor to scientific periodicals, and was for a time American editor of the *Repertoire de Chimie appliquée*. In book-form he published, with Charles W. Eliot (now president of Harvard University), *Manual of Inorganic Chemistry* (1868) and *Manual of Qualitative Chemistry Analysis* (1869); *Cyclopaedia of Qualitative Analysis* (1870-73); and *Agriculture in Some of its Relations with Chemistry* (2 vols., 1887).

STORMS. See TORNADO.

STORRS, RICHARD SALTER, Congregationalist pastor and author, was born at Braintree, Mass., Aug. 21, 1821. He graduated at Amherst College in 1839, and entered on the study of law under Rufus Choate, but then turned to theology. He graduated at Andover Seminary in 1845, and became pastor of a church at Brookline, Mass. A year later he was called to take charge of the newly organized Church of the Pilgrims at Brooklyn, N. Y., and has since continued in that position. From 1848 to 1861 he was one of the editors of the *Independent*. He is noted for his eloquence and is an advocate of preach-

ing without notes. He has published *Constitution of the Human Soul* (1857); *Early American Spirit* (1875); *John Wycliffe and the First English Bible* (1880); *Recognition of the Supernatural* (1881); *Manliness in the Scholar* (1883); *Divine Origin of Christianity* (1884).

STORY, WILLIAM WETMORE, sculptor, was born in Salem, Mass., Feb. 12, 1819, and was graduated at Harvard in 1838. He was the son of the renowned jurist, Joseph Story (for whom, see *ENCYCLOPEDIA BRITANNICA*). Law first claimed the son's attention also; he was admitted to the bar, and became known as the author of treatises on the *Law of Contracts* (1844) and *Law of Sales* (1847), and other legal tomes. But he also contributed to various periodicals, delivered poems on several occasions, in 1847 brought out his first volume of poems, and in 1851 published *The Life and Letters of Joseph Story* (2 vols.). The direction in which his tastes lay had already been indicated in some of his writings, and in 1848 he went to Italy, where he has since devoted himself chiefly to art. He has modelled portrait-statues of his father, Edward Everett, and George Peabody; busts of Theodore Parker, Josiah Quincy, and James Russell Lowell; and a number of ideal works, among them Sappho, Saul, Cleopatra, Delilah, Helen, Jerusalem in her Desolation, Semiramis, Judith, Sardanapalus, and Thetis and Achilles. Some critics have seen talent rather than genius in these thoughtful, carefully executed works, but, though not strikingly original, they are noble and pure in sentiment, the products of a highly cultivated mind. In Europe he has been regarded by many as the foremost among American sculptors. As an author he is almost equally well known, and has published *Roba di Roma*, sketches of Italian life, *Proportions of the Human Figure*, and various volumes of poems, including *Graffiti d'Italia* and *The Roman Lawyer in Jerusalem*. (F. L. W.)

STOUGHTON, JOHN, English Congregationalist author, was born at Norwich, Nov. 15, 1807. He was educated at Highbury and University Colleges, London, and became pastor at Windsor in 1832, and at Kensington in 1843. He was chairman of the Congregational Union in 1856, and became professor of historical theology and homiletics in New College, St. John's Wood, London, in 1872. He resigned this post in 1884, having resigned his pastorate also in 1875, when he received a testimonial of £3000. He was a delegate to the conferences of the Evangelical Alliance at New York in 1873 and at Basel in 1879. He has been active with his pen and has published many books relating to English church history. Among them are *Church and State 200 Years Ago* (1862); *Ecclesiastical History of England* (6 vols., 1867-81); *Religion in England, 1800-1850* (1884). Among his popular biographical works are *Philip Doddridge* (1851); *Haunts and Homes of Martin Luther* (1875); *Worthies of Science* (1879); *William Wilberforce* (1880); *William Penn* (1882); *John Howard* (1884); *Italian Reformers* (1881); *Spanish Reformers* (1883).

STOVES. Several localities have laid claim to the first manufacture of stoves in the United States. In 1741 Benjamin Franklin invented what he called a "Pennsylvania fireplace," consisting of several plates of cast iron with a "shutter" to regulate the draught and a "register" to distribute the heat properly. In 1744 Franklin printed, from his own press, a description of the Pennsylvania fireplace. The book begins by stating that in the Northern colonies fires were necessary seven or eight months in the year; and that wood was becoming scarce, and even then had to be carried as much as 100 miles before it was used. Therefore the writer had invented the Pennsylvania fireplace in order to save something of the large quantities of wood that went to waste in the generous fireplaces of those days. There were then

in use in the colonies, to a very limited degree, Holland stoves with doors opening into the room and with a flue from the top. The German stoves, also in use, had doors upon the outside of the building or in some other room. While they gave a good heat yet there was the objection that the fire could not be seen. In addition to Holland and German stoves there was a limited use of charcoal fires in pots for the heating of chambers; but with the great objection that the gases generated often proved dangerous. Franklin's stove was a great improvement on all that had preceded it. The principle of its action was the same as that of the air-tight stoves introduced many years later. Indeed, it would have been air-tight had it been possible at that time to make the castings sufficiently close-fitting. Almost at the same time that Dr. Franklin wrote, John Potts made stoves at Pottstown, Pa.; but no description of these is given. There are stoves in existence to-day, bearing the date 1756, and manufactured by J. Gluninger & Co., at Huntingdon Springs, Pa. The plates are nearly one inch thick. About 1757 Henry William Stiegel (known as Baron Stiegel) came to Lancaster County, Pa., and built the Elizabeth furnace in the town of Mannheim. He also built a furnace and a fortified place in Lebanon County, where he cast the six-plate stoves which were among the first of the kind in the country. He was rapidly developing his industry when the war of the American Revolution made it impossible for him to meet his liabilities. In 1767 William Lyle, of New York City, made the first hot-air furnace. It consisted of heavy plates about 30 inches square on the side. From 1770 to 1775 Franklin also invented several other stoves, among them two or three for the burning of bituminous coal. One of these had a downward draught, and consumed its own smoke; the other had a basket grate or cage, with movable bars at the top and bottom, which, after being filled and kindled at the top, could be inverted, and so made to burn at the base.

Between 1785 and 1795 Benjamin Thompson, known as Count Rumford (see THOMPSON, in the *ENCYCLOPEDIA BRITANNICA*), devised several improvements in stoves, ovens, etc., all intended to economize fuel and heat. Soon after the Revolutionary war George Youle established a stove store in Water Street, New York, where he made galleys for the navy. In 1812 Charles Postly made a nine-plate stove of an oval shape with the fire directly under the oven and with openings on the sides in which tubular boilers were placed.

Previous to 1825 the use of stoves, generally of the box pattern, and of a very rude construction, was confined to stores, hotel bar-rooms, school-houses, and churches in the cities and larger towns. In these churches the stoves were sometimes raised on stilts that the people in the galleries might be warmed. Country churches were not usually heated, but the older women carried their foot-stoves and the men protected their feet with stout leather overshoes, known as "boxes." In the residences of some of the more wealthy city families cannel and other English coal, generally referred to at the time as "sea-coal," was burned in imported grates or in Rumford stoves, lined with fire-brick. A large number used the Franklin stove as an open fireplace, burning wood in it. A still greater number used the capacious, old-fashioned fireplace. The cheapness of fuel, the cheerfulness of an open fireplace, and the great weight and rough construction of the stoves of those days, made the latter in but little demand. After the opening of the Erie and Champlain canals, the introduction of river steam-boats, and the beginning of railroad travel, the facilities for transporting heavy goods were so much increased that the manufacture of stoves soon became a leading industry.

These were wood-stoves, but anthracite coal, which was gradually coming into use wherever a high degree of heat was required and a strong draught possible, was destined to create a revolution in the business.

Anthracite coal came into use about the year 1820, when but 365 tons were sent to the market. A new kind of stove was required for anthracite, in which the draft of air would be much smaller. One of the earliest in this field of invention was Dr. Eliphalet Nott, who spent several years in perfecting his inventions for heating. The chapel of Union College was heated by one of his stoves, in which the base-burning principle was used. There was also a marvellous kind of box stove, which was attributed to the genius of Dr. Nott. The iron was about an inch thick and could be neither broken nor bent. Dr. Nott, however, did not have the first patent on anthracite stoves. His was the third, it being issued in 1832. The first patent went to Anthony Savage, of Pottsville, Pa., in 1830; and the second to Jordan L. Mott, of New York, in 1832. The latter showed that the anthracite fire could be made from nut- and pea-sized coal, and established several other facts concerning the laws of combustion, so that anthracite coal stoves became salable.

From their position at the foot of the Erie Canal, and at the head of navigation on the Hudson River, the cities of Albany and Troy early became great centres of the stove industry. Fortunately for them both, the best moulding sand in the country was close at hand. The first cooking stoves manufactured in these cities were of the old ten-plate oval pattern, the oven above the fire. About the year 1860 the question of burning anthracite coal from the bottom of the magazine within the stove was widely discussed, but it was found that Littlefield, of Lowell, had in 1852 patented a base-burner covering the chief points that the inventors of 1860, and later, had attempted to cover. From that time the use of base-burners has increased in a marvellous degree.

What are known as gas stoves are simply enlargements or adaptations of gas-burners to the process of heating. Vapor stoves were invented about 1863 as a means of vaporizing the products of petroleum. They are, practically, nothing more than large lamps adapted to other purposes than lighting.

Stove Factories.—A description is given of a leading factory in the city of Albany. The ground consists of about 5½ acres, the establishment being one of the largest in the country, having a capacity of about 500 hands, whose skilled labor is capable of making from 100 to 200 stoves a day of every description, from the mammoth hotel-ranges and heaters to the oil and vapor stoves, including parlor and cook stoves, furnaces, ranges, together with stove fixtures of every possible style. The main building, in which are contained the general and manufacturing offices, show-room, mounting, repair, shipping, nickel-plating, oil stove, and general storage departments, is 200 × 71 feet, 4 stories in height, with a basement, and is built of brick. This building is supplied with two large elevators capable of sustaining any desired weight. In the pattern-makers' department every pattern, constructed from the best of soft woods, is formed almost entirely by hand. Here some of the most skilled workmen are to be found, since much depends on the pattern as to the success of the casting. In the nickel-plating room the different pieces of the stove undergo the nickeling process, after which they are removed to a room adjoining, and burnished on emery and felt wheels. Near the main structure is a building, 50 × 50 feet, constructed of brick and 2 stories high, that is used for the casting and cleaning departments on the first floor, and a tin shop on the second. The buildings adjoining this contain the engines and

boilers. One of the former has a capacity of 250 horse-power and the other of 50. The latter engine is used principally to run the dynamo that furnishes electricity for lighting purposes. The boilers are sufficient to furnish enough steam to supply both engines and also heat the several departments thoroughly in the most severe weather. The japanning department, fitted with all the modern appliances for the successful prosecution of this work, adjoins the main building on the south. A building, 100 × 24 feet, 2 stories high, also constructed of brick, adjoins the scratch shop. This contains the facing room, ladle oven, blacksmith and carpenter shops on the first floor, while on the second floor are the iron and wood pattern shops, the latter being located at the southwest corner of the building. Every pattern is made from drawings supplied by draughtsmen regularly employed for this purpose. The work is almost entirely executed by hand, entailing a heavy expense and the consumption of considerable time. It is necessary that the greatest care should be used in the manufacture of the patterns, as the least flaw can easily be detected in the castings. A fourth building, 90 × 30 feet and 3 stories high, stands west of the main structure on the north line. This is used principally for the storage of coal and wood and general supplies. Adjoining this is a three-story brick structure, 20 × 23 feet, which is also used for general storage on the first floor, while the two upper apartments are given over to the use of the employes. At the west of these buildings is a huge structure, 130 × 281 feet, known as the moulding department. It is built of wood filled in with brick, and has a gravel roof. This building contains 150 "floors," a technical term applied to that section of a moulding room where flasks are repaired. Centrally located on the east line of this building are three cupolas for melting the iron, which is done by blasts supplied by two "blowers" that are located in the engine-room. The 250-horse-power engine used to drive the blasts is of low pressure, perfectly reliable, and capable of doing the work required of it. These cupolas have a capacity of about 20 tons of melted iron per day. Located midway between the moulding and scratch-shop buildings is the mill room, wherein are several "mills" that are revolved continuously for the purpose of "milling" or removing the spraws and cinders from the castings. West of the moulding shop is a building, 12 × 36 feet, containing the moulding and other sands used in the manufacture of stoves. There are also some dwellings and stables on the extensive grounds. While the buildings themselves do not cover fully five acres, the land not covered with buildings is devoted to the storage of lumber, pig-iron, flasks, etc. The buildings are perfectly adapted to the use for which they are intended. Each department is heated by steam and lighted by electricity; for the former, iron pipes run about the several buildings and the steam is supplied from the mammoth boilers adjoining the engine-room. The buildings may be considered practically fire-proof; automatic sprinklers are attached to water-pipes that are fastened to the ceilings of the several apartments. These sprinklers are at a distance of 8 feet apart, and the pipes are always kept filled with water. In the event of any apartment being on fire the heat will melt the solder, thus allowing a cap to drop down and the water to spurt into the burning room. The water thus released covers a distance of 8 feet in either direction. The moment the water in the pipes is released, it removes the pressure upon a large tank containing about 9000 gallons of water, and the automatic pump is immediately set in motion and renews the water-supply. Every department is supplied with the automatic sprinklers except the

moulding shop, which has seven hydrants, with 450 feet of hose always attached for immediate use. The force of water from the hydrants is sufficient to throw two 4-inch streams over any of the buildings. These hydrants are so constructed as to be quickly reached and used to advantage from either the inside or outside of the moulding shop. The works, when in full working order, have a capacity of from 100 to 200 stoves a day.

The chief centres of the stove-making industry in the United States, aside from Albany and Troy, already noted, are Boston, Cincinnati, Philadelphia, Buffalo, Louisville, St. Louis, Cleveland, Pittsburgh, Detroit, Chicago, and Kansas City.

(F. G. M.)
STOWE, CALVIN ELLIS (1802-1886), clergyman, was born at Natick, Mass., April 26, 1802. He graduated at Bowdoin College in 1824 and at Andover Seminary in 1828, then becoming a teacher there. In 1831 he was made professor of Greek and Latin in Dartmouth College, and in 1833 accepted a call to be professor of biblical literature in Lane Theological Seminary at Cincinnati. While there he married in 1836 Miss Harriet Beecher, whose career has been sketched in Vol. I. in connection with the Beecher family. In 1850 her husband went to Bowdoin College as professor of natural and revealed religion, and in 1852, just as her remarkable work, *Uncle Tom's Cabin*, was becoming known, he was made professor of sacred literature in Andover Seminary. He discharged the duties of this position until 1864, when he retired. He died, Aug. 22, 1886. At the beginning of his career he translated, with additions, Jahn's *Hebrew Commonwealth* (1828), and Lowth's *Lectures on Hebrew Poetry* (1829). He afterward published a report on *Elementary Public Instruction in Europe* (1838), and some other works on education. After retiring from his professorship his lectures were summarized in his *Origin and History of the Books of the Bible* (1867).

STRAIN, ISAAC G. (1821-1857), naval officer and explorer, was born at Roxbury, Pa., March 4, 1821. In 1837 he entered the navy as midshipman. In 1845 he led a small exploring expedition into the interior of Brazil, and in 1848 he made a personal exploration of Lower California. In 1849 he crossed South America from Valparaiso to Rio Janeiro, and published an account of his journey under the title, *The Cordillera and Pampa* (1853). In 1850 he was promoted lieutenant and was attached to the commission that determined the boundary-line between the United States and Mexico. Afterward he commanded an expedition to explore a line for a canal across the Isthmus of Panama. The party suffered extreme hardships, losing several of its members, and the heroism Strain displayed first attracted public attention to him. An account of the expedition, compiled by J. T. Headley, appeared in *Harper's Magazine* in 1856. In 1856, sailing in the Arctic in the North Atlantic, Strain ascertained by soundings the practicability of a telegraphic cable between the United States and Great Britain. His death, due to exposure on the isthmus, occurred at Aspinwall, May 15, 1857. Among his interesting papers communicated to the American Geographical Society was one on *The History and Prospects of Inter-oceanic Communication* (1856).

STRAWBERRY, a plant of the order *Rosaceæ*, genus *Fragaria*, which bears one of the most delicious of our small fruits, and is widely cultivated throughout all civilized lands. The name is of Anglo-Saxon derivation, and probably comes from the wandering habit of the plant, being a corruption of *stræ*. The strawberry-plant is a stemless, perennial herb, with compound leaves of three coarsely serrated leaflets. It multiplies by runners, or un-

derground branches, which form buds and develop roots and leaves, the runner then losing its connection with the parent plant by decaying, so that the new plant becomes independent. The flowers are 5-petalled, mostly white, with numerous stamens and simple pistils. They are seated on a convex receptacle which greatly enlarges in the fruiting season, and becomes pulpy and edible. This swollen receptacle, which is popularly considered the fruit, is really only the end of the flower-stem, greatly altered, and bearing the real fruit in the ripened ovaries scattered over its surface, or sunk in little depressions in the succulent mass.

The strawberry is found in all parts of the northern temperate zone and in the mountains of South America, and has several species native to the United States. Of these the best known is *Fragaria Virginiana*, the Virginian or common wild strawberry, which extends from the arctic regions to Florida, and from the Atlantic to the Rocky Mountains. In this species the leaves are rather long and sharply serrate, of a light-green color, the fruit mostly globular and bright-red in color, with deep pits on its surface, in which the seeds are sunk. There are many varieties of this species, and it has been described under various names. The cultivated varieties are mostly derived from this species and *F. vesca*, the Alpine or wood strawberry, the common European species, but indigenous also in the northern portions of America, where it extends from the Atlantic to the Pacific. This species bears rather small flowers, and thin, pale-green leaves, the flower-stalks longer than the leaves. The fruit is small and sweet, parting freely from the calyx, while the seeds are attached to the surface, and not sunk as in *F. Virginiana*. This was the first species to be cultivated, there being records of its culture in England more than 400 years ago. Of other American species the most important is *F. Chilensis*, the Chili strawberry. It is found on the Pacific coast from Oregon southward, and bears very hairy, thick leaflets, with large yellowish-white or rose-colored flowers, and a fruit sometimes as large as a small hen's egg. It is of a pale color and insipid taste, but has yielded valuable varieties by hybridization. The Indian species, *F. Indica*, from upper India, is naturalized in the Southern States. It differs greatly from the other species, and bears showy yellow flowers which give it value as an ornamental plant; but its fruit is dry and tasteless.

By the abortion of the stamens some species of the strawberry are rendered more or less diœcious, and modern culturists divide the varieties into two classes, the staminate or male, and the pistillate or female. In the latter the stamens are aborted and bear little or no pollen, while the former have usually a small number of pistils. The greatest bearers are

Strawberry.
Perfect Flower.

Pistillate.

mostly of the pistillate variety, but they, being nearly incapable of self-fertilization, are fertilized by planting staminate plants near them. The difference can be readily distinguished when the plants are in blossom, and in selecting plants for this purpose it is necessary to choose varieties that flower about the same time. The present tendency of growers, however, is to discard the unisexual kinds. As regards

See Vol. XXII.
p. 592 (p. 621
Am. Rep.).

the cultivation of the strawberry the same general rules as to soil, drainage, manuring, etc., apply as in the case of other small fruits and vegetables. It needs a good, deep, rich soil, and clean cultivation between the rows, with a renewal of the plants as often as once in three years. They are planted in rows about a foot apart, the rows needing to be kept clear of runners as well as weeds. The plants are set a foot apart in the rows. They are raised from the well-budded runners of the preceding autumn, set out in early spring, or by transplanting in June after the fruit has been gathered, though early autumn is not too late for this work. In the far north the plants are often covered with hay or straw for protection from frost, they growing through the straw, which serves to keep the fruit clean.

There are a great many varieties cultivated, the first important step in this direction in the American culture being in the appearance of Hovey's Seedling. This has not been excelled in quality. The next important variety was Wilson's Albany. To these have been added many favorite varieties. The strawberry, if cultivated with care and close attention to weeding, is a profitable crop. The fruit rarely sells at a less average than \$8 per hundred quarts, while careful cultivation will give at least 5000 quarts per acre, so that the crop, even at the lowest average rates, is fairly profitable. The strawberry season, formerly very brief, has now been greatly extended by the transportation of the fruit from long distances, the Northern market being supplied at first from Georgia, and then from States up the coast to New Jersey, which furnishes the principal supply to New York and Philadelphia. Later in the season the fruit from Connecticut and Massachusetts comes into market, so that the annual supply of this favorite fruit, once confined to two or three weeks, is now extended over as many months. (C. M.)

STREATOR, a city of Illinois, is on the Vermilion river in the southern part of La Salle county, 90 miles S. W. of Chicago. It is at the junction of the Chicago, Burlington and Quincy, the Wabash, and four other railroads. In the vicinity are 22 bituminous coal mines, whose annual output is over 1,200,000 tons. There are also large works, manufacturing plate and window glass and bottles, 4 tile factories, 3 foundries, railroad and machine shops, a paper-mill, flouring and planing mills, and coke works. Streator has 2 national banks, 1 private bank, 5 weekly and 3 daily newspapers, 16 churches, a commercial college, high school, and other public schools. The city, picturesquely situated on a high bluff, has gas, electric light, water-works, etc. Its property is valued at \$6,000,000; its public expenses in 1887 were \$65,000, and it has no debt. It was first settled in 1866 and incorporated in 1881, having then a population of 5157.

STREET, ALFRED BILLINGS (1811-1881), author, was born at Poughkeepsie, N. Y., Dec. 18, 1811. He received his education at Dutchess Academy, and afterward studied law under his father, commencing practice in Albany. In 1839 he removed to Albany and, after editing a newspaper for two years, was in 1848 appointed State librarian, which position he held till his death. From his youth up he contributed largely—chiefly poetical pieces—to magazines, some of his productions receiving high commendation from critics, and several being translated into German. His published poetical works comprise: *The Burning of Schenectady* (1842); *Drawings and Tintings* (1844); *Fugitive Poems* (1846); *Frontenac* (1849). His prose works are: *Woods and Waters, or the Savanacs and the Racket* (1860); *A Digest of Taxation in the United States* (1863); and *The Indian Pass* (1869). Collected editions of his poems appeared in 1847 and in 1866. He died at Albany, N. Y., June 2, 1881.

STREET RAILROADS are an institution peculiarly American, both in original conception and in development. The first horse-car for service in the streets of any city was built in 1831. This car consisted of three compartments, each compartment holding ten persons, and being entered by separate doors on the side from a guard-rail. Seats were provided on top of the car for 30 or more persons. The car was very much like the English railroad coach, though it was set considerably lower. It was hauled by a team of horses, the conductor remaining outside on the rail. It was built for the New York & Harlem Road, which ran from Prince Street, on the Bowery, in New York City, along the line of the present Fourth Avenue (not then opened, though surveyed in 1810) to Yorkville and Harlem. The fare paid varied with the distance, being sixpence (or 6½ cents in Spanish silver currency then in vogue) from Prince Street to 14th Street, and increasing by sixpence for other distances until it was 25 cents to Harlem. In time through fare was reduced to 18 pence, and then to 12, but the road did not succeed. In 1837, after six years of continuance, it temporarily gave way to steam-cars. In 1845, however, it resumed working under its charter, which had not been given up, and which is still used for the present Fourth Avenue horse-car line. The cars were then remodelled nearly to their present style, by the adoption of end platforms and entrances. Similar cars ran in Philadelphia from the centre of the city to Gray's Ferry, on tracks used chiefly for a freight railroad. No other horse-car line was built in New York till 1852, when at about the same time charters were granted for the Second, Third, Sixth, and Eighth Avenue lines. Boston was the next American city to adopt the new system, in 1856, and Philadelphia followed in 1857, after which it spread over the country. New Orleans, in 1861, was the first to adopt the small car, or, as it is called, the "bobtail" car. In 1860 George Francis Train started a "tram-way" in Birkenhead, opposite Liverpool, England. Popular feeling was against the idea, and the company did not declare a dividend in 20 years. So intense was the popular prejudice in England at that time, that the starting of a horse-car in London caused a riot, and the rails were torn up. Nor could an act of Parliament be obtained until as late as 1870 for the construction of other roads. Now lines are operated in the American style in most of the principal cities in Great Britain, the cars, by their combination of lightness, durability, and comfort, having won the day against English manufacturers. In 1866 the countries of South America took up street-railroad enterprises on a large scale, Brazil, Venezuela, Chili, Peru, Uruguay, Ecuador, and the Argentine Republic, as well as Costa Rica, all adopting them. Cars manufactured in the United States are now sent to all civilized countries—to New Zealand, Australia, Java, India, Japan, South Africa, as well as to Canada, France, Belgium, Portugal, Austria, Holland, Germany, Russia, Sweden, Norway, and England. The chief centres in the United States for the manufacture of horse-cars are Philadelphia, New York, Troy, and St. Louis. The English cars differ from American cars in having winding stairs at each end, by which to reach the seats on top of the cars. The fares in England and in most European countries are so much a mile. In Paris the cars are allowed to carry only a certain number of passengers—10 standing on the front platform, 10 on the rear platform, and as many in the car as are allowed to have seats. Those inside pay 50 centimes (10 cents), and those outside 25 centimes. When a car has its complement the gates are shut, a sign is hung out reading, "Complet," and no one can enter. During the busy time

of the day, between 5 and 6 o'clock, when crowds are waiting for a car, it is necessary to apply at the office for a numbered ticket. The holder of a number is obliged to wait until it is called by the driver: a plan which causes inconvenience until the holder has gained his seat, but afterward it enables him to take the trip much more comfortably than the custom of crowding which prevails in America.

When street railways were first introduced, one of the most serious problems of construction was that relating to the shape of the rail. For railroads running through the country the T-rail answered every purpose, and nothing for such use has been found to supersede it to this day. But it was necessary to lay such tracks in cities that ordinary vehicles, running along or across them, should meet with as little obstruction as possible. The old Philadelphia pattern of street rail was first used for this purpose, and many tracks of this kind are still in existence. This is known as the "side-bearing" rail. During a few years past the "centre-bearing" rail has come into general use. The latter, after being worn down, has the advantage of being able to be reversed so as to present a fresh rounded edge upon which the wheel may take hold. The crown projects above the brim, or the level of the pavement, from 1 to 1½ inch. All the railroads in the United States are now using steel rails, as they are cheaper as well as better than the iron rails formerly used, but no longer manufactured in this country. The steel rails used here are all of American manufacture. The duty on imported steel rails is \$17 a ton, and ordinary American steel rails can be purchased for \$29 a ton, which is just \$1 more than the duty before the reduction of the tariff went into effect. The "life" of a steel rail is from 10 to 20 years, according to the nature and amount of the traffic.

Efforts have been made in the legislatures of several States to remove the bobtail cars, in which the passengers are obliged to discharge some of the duties of conductors. The extra work of the drivers in seeing that passengers pay their fares is the cause of frequent accidents in large cities.

It is considered that some motive power other than horses must be substituted in all of the cities; but it cannot be determined yet what that power is.

Improvements in motors are in progress; and in many of the cities the cable is superseding the use of horses. (See *ENCYCLOPEDIA BRITANNICA*.) Experiments are in progress with electricity as a motive power; and some of them have proved successful. A line of street railroad in the city of Binghamton, N. Y., is carried on by a "traveller" which runs on a wire suspended above the track. The traveller follows the car, and makes the electric circuit complete with a wire that parallels one of the tracks.

Motive power from storage batteries has also been tried. (See *TRACTION, ELECTRIC*, in *ENCYCLOPEDIA BRITANNICA*.)

The largest electric railroad in operation in the United States is at Montgomery, Ala. It is 13 miles long, has 18 cars, and the steam-power costs \$14 per day, or an average of from 75 to 80 cents per car. Other roads operated are as follows: Windsor, Canada, 2 miles, 2 cars, with steam-power at \$4 a day; Detroit, 2 miles, 8 cars, steam, \$6 per day; Appleton, Wis., 5 miles, 5 cars, water-power, \$4.50 per day; Port Huron, Mich., 5 miles, 5 cars, natural gas, \$3.50 per day; Scranton, Pa., 4½ miles, 7 cars, coal culm or dust, \$7 a day; Lima, Ohio, 4 miles, 6 cars, crude oil, \$4 per day; St. Catharines, Ontario, 6 miles, 6 cars, water-power, \$4 per day. Electric motors are soon to be used, as follows: Jamaica, N. Y., 6 miles, 10 cars; Omaha, 7 miles, 10 cars; Dayton, Ohio, 6 miles, 12 cars; Ansonia, Conn., 3½ miles, 4 cars. It is said that the cost of maintaining the motor will not exceed that of machinery in any shop. The mo-

tor can be made to run at any speed that will be allowed, and will far excel the horse in this respect. In Scranton speed is obtained at an average of about 15 miles an hour.

The following details of the method used in Scranton show how electricity is applied to the moving of surface railroad-cars. When open cars are driven, one motor of 20 horse-power is placed in the middle of the car and all of the wheels are driving-wheels, the connection between the motor and the wheel-axles being made by means of chains and sprocket-wheels. But when closed cars are driven, a motor of 15 horse-power is placed on a closed platform at the front of the car; the forward wheels only are driving-wheels, and their connection with the motor is made in the same way as on the open cars, with chains and sprocket-wheels. The company intends to use also larger cars, each with a motor of 25 horse-power, which will not only propel themselves but be able each to haul two other cars, loaded with passengers, up all the grades. The average speed attained is more than 8 miles an hour, and there is no difficulty in going much faster; in fact, the men in control of the cars have to be watched to prevent their running at excessively high speed. At the generating station there are 2 stationary engines of 100 horse-power each, 2 dynamos of 100 horse-power each, and 4 boilers of 100 horse-power each; only one engine and dynamo, however, and two of the boilers being in use at the same time. The duplicate engine, dynamo, and boilers are for the purpose of providing against contingencies of accident to those in use, and also to allow of alternations in service, thus giving opportunities of frequent examination and inspection. Upon this railway the overhead system of conduction is employed, having flexible connection between the motor on the car and the carrier traversing the conductor, which is a solid copper wire, ½ inch in diameter, suspended on a part of the route from transverse wires attached to wooden poles, 20 feet high and 6 inches in diameter, placed, at distances of 100 feet, on both sides of the street. On the rest of the line the wires are suspended from arms projecting sideways from wooden poles at the side of the railway, about 20 feet above the ground. As the line is a single-track railroad, there are several turn-outs, or passing places, at which points the electric overhead conductor branches off over the side track also; and an ingenious system is in use by which the carrier, running upon the overhead wire with two grooved wheels of about 2½ inches diameter, automatically shifts the connections at the points of divergence from the main line, so that the carrier always follows that one of the overhead conductors which is above the track upon which the car is travelling. The return current of electricity is taken by the rails. The electrical current has a tension of about 600 volts, which, while sufficient to give a shock, could not produce any dangerous effect on man in case the current should by any means be diverted. Part of the road is laid with tram-rails and the rest with T-rails, and only part is paved, so that these different conditions, in connection with the many grades and the curves and turn-outs, thoroughly test the working of the system. The noise of the carriers running on the conductors is not great, but the noise produced by the motors and the chain and sprocket connections is annoying. This could be entirely avoided by the use of a noiseless motor and a better method of connection. Noiseless and durable electric motors suitable for use on cars can be had, in which the weight per horse-power does not exceed 60 pounds. Electric railways with overhead conduction have shown their capability to propel a few cars, even if heavily loaded, at less cost and much greater speed than can be obtained by horse-power.

In the case of electrical railways with underground conduction, the effort has been made to give all the advantages of the overhead system. On account of the serious objection in most cities to having the conductors and poles or other supports obstructing the streets, attempts have been made to secure electric railways with underground conduction. But the costly conduit, and the needful arrangements for drainage and for cleaning out, together with the increased care necessary to provide against the considerable loss or leakage of electricity, which, nevertheless, generally takes place in spite of all precautions, detract greatly from the apparent advantages of the plan. Many inventions have been patented, and various devices contrived to overcome the objections of this method, but practical success has hardly yet been obtained. Neither by overhead nor underground conduction have more than a few cars as yet moved simultaneously upon railways, although many ingenious arrangements are offered by inventors who confidently assert they can run any required number of cars. Both plans also are open to another serious objection in the entire stoppage of travel on the whole line in case of breakage or derangement of any part of the conducting apparatus or the generating machinery. In this respect they suffer from the same disability by which the cable system of car-traction is hampered. Possibly by suitable arrangements of duplicate engines, boilers, and dynamos, duplicate conductors, and auxiliary, sectional, or relay systems of conduction, this disability may yet be reduced to insignificant proportions. Taken altogether, underground conduction does not compare favorably with overhead conduction up to this time. One great trouble with the latter plan, however, is that although it can be used to great advantage and economy on lines running a few cars in towns or in suburban districts outlying large cities, it will probably never be allowed by the municipal authorities in large cities, which, of course, are the very places where the advantages of electrical propulsion are needed the most. To move a large number of cars, as, for instance, upon the Third Avenue or Broadway lines in New York City, the electrical conductor, whether overhead or underground, must be of great size if the current is of low tension; while, on the other hand, if a small or moderate-sized conductor be used, the current must then be of dangerously high tension, and, of course, it would then be very difficult to avoid great loss of electricity from leakage.

In the accumulator or secondary-battery system, each car carries its own supply of energy, and is entirely independent of any method of continuous electrical conduction. No change of track or roadway is required, nor any costly conduit or unsightly poles or other supports, while the cars can run anywhere that a car can be taken by horses. These points are of great advantage, and are its chief merits, independent of its economy, over horse-power. In practice, cars of the size of the usual 2-horse cars are provided with about 80 accumulators, weighing when filled with fluid and ready for use about 40 pounds each. These cells are placed under the seats on each side of the car. Their combined weight is 3200 pounds, and the weight of 2 motors, each of 5 horse-power, should not, together with their connections to the car-axles, exceed 800 pounds so that the additional weight imposed upon the car is about 4200 pounds, which allows 200 pounds for the apparatus to control the current and for other electrical appliances. This added weight, if placed upon a 4-wheel car, may be of disadvantage to the car or to the track. If this should be the case, the difficulty is removed by the use of 8 wheels on 2 swinging trucks, which support the car much better, and distribute the weight upon the track. Both

these kinds of storage-battery cars are in service with entire success. The charging of the cells is done by a dynamo driven by steam-power or any other desirable means, and it takes 4 hours to charge cells which are able to perform 4 hours' work. To remove from the car the cells which have done their work and to replace them by freshly charged cells takes no more than the time required to change horses. It requires 10 horse-power exerted for 4 hours, making 40 horse-power hours, to charge the batteries or cells of each car. The cost of running large stationary steam-engines of 200 to 400 horse-power, constructed with the modern improved cut-off appliances and other economical devices, has been found not to exceed $\frac{1}{3}$ cent per horse-power hour. This allowance includes fuel, attendance, repairs to engine and boilers, oil, etc. At 1 cent per horse-power hour the whole cost of a day's supply of electricity would be \$1.60. The expense of horses for the same work and time is not less than \$4.50. With motors properly constructed a speed of 8 or 9 miles per hour is readily accomplished—in fact, 8 miles per hour may be taken as the speed at which such motors will work to the best advantage and return the greatest percentage of mechanical efficiency. The requirements of street-car service demand variable rates of speed; as, for instance, in crowded streets, behind other vehicles, or in turning curves and entering switches it is necessary to go slowly and cautiously, and the weight of the load carried at different times varies from an almost empty car to one overloaded. These conditions, together with increased power needed to ascend grades and to start loaded cars, especially on up-grades, call for electric motors which will, under such greatly varying circumstances, respond at all times almost equally well. There are motors which, while engaged in performing an equable work and running at an equable speed, for both of which purposes the motor was specially made, will return 90 or possibly 95 per cent. of efficiency, while the same motor, when run at some different speed or under some different load, may return but 30 or 35 per cent., so that the average performance of such motors in street-car service would probably give only 50 per cent. return of efficiency. Motors can, however, be obtained which will, under all the variations of street-car work, constantly return 75 per cent. of efficiency.

A uniform rate of 5 cents is charged in almost every city of the United States. There are, however, street railroads which require from 6 to 10 cents because extra power is required upon hills, or because of long stretches of unoccupied territory along the tracks. A very careful investigation of the earnings of certain street railroads in New York City and Brooklyn, by the State board of railroad commissioners, has resulted in a statement that nearly all of them required but little over 4 cents per passenger in order to pay expenses, interest, and 10 per cent. yearly of the cost of the road and the equipment. In 1886 all the street railroads of New York City carried 206,000,000 passengers; while in 1887 the number was but 200,000,000. The several elevated railroads carried 115,000,000 passengers in the former year and 159,000,000 in the latter. The elevated railroads had scarcely begun their operations when the disadvantages of the surface roads became apparent; and the proprietors of the latter were stimulated to make great improvements. After various legislative attempts to guard the interests of the public, a general law was passed by the New York legislature, in 1884, for the construction and operation of street surface railroads in that State. Power was given to local authorities to make regulations as to the rate of speed, the mode of use of tracks, the removal of snow and ice, and the enforcement of compliance with all of these requirements under

heavy penalties. The rate of fare was limited to 5 cents. It was also provided that new roads may use the tracks of an old road for a distance not to exceed 1000 feet; and that all street surface companies may use any kind of power except steam. Immediately after the passage of this act, three companies (one being the Broadway) were formed to operate surface railroads in the city of New York. In 1886 a new law was passed to secure adequate compensation for the right to construct, maintain, use, operate, or extend street railroads. Stringent provisions were made in relation to giving such privileges to the highest bidder.

(F. G. M.)

STRIKES are combinations of workmen to enforce a demand for higher wages, and occasionally to obtain other ends, by refusing to labor under the rates and regulations of their employers. The word as used in this sense is much more recent than the thing. A strike on a large scale occurred in England after the plague of 1340, with destructive consequences to the harvests and to general business; the prevention of similar movements was aimed at by a statute of labor which required the poor to work at the old rates for any employer, and forbade them to move from one place to another, under various penalties.

In the United States strikes began at an earlier period than has usually been supposed. The journeymen bakers of New York struck in 1741, and were tried for conspiracy. An association of journeymen shoemakers in Philadelphia ordered strikes for increase of wages in 1796 and 1798; these were successful, and one to resist a proposed reduction in 1799 was partly so. The sailors' strike in New York, November, 1803, which was long thought the first in America, employed compulsion, and did not succeed; nor did another of the Philadelphia shoemakers in 1805. A "general turn-out" was ordered by the New York cordwainers in November, 1809: the term "scab" was at this time applied to the unfaithful member of a journeymen's association. In 1815 several cordwainers were tried and convicted of conspiracy at Pittsburgh in connection with a strike. Some ship-builders at Medford, Mass., struck in 1817 for continued supplies of rum. The employment of a "rat" or non-union printer, at Albany, caused a strike among the printers there in 1821. In 1822 three hatters of New York were convicted of conspiracy. Sundry strikes of ship-carpenters and calkers occurred along the coast, 1825-30; one of tailors in Philadelphia, 1827, for the reinstatement of discharged comrades; one of laborers on the Chesapeake and Ohio Canal, 1829; and several of carpenters, masons, and machinists, in Boston and elsewhere, for fewer hours of labor, 1830-31. From this date strikes were so frequent that only the more important or significant of their incidents need be noted. The Boston merchants and ship-owners, at a meeting held May 15, 1832, resolved to employ no member of the unions. An unsuccessful strike of women engaged in binding shoes took place at Lynn, Mass., in January, 1834. Schuylkill merchants agreed on a lock-out, May 26, 1835; during this year various trades in Philadelphia were troubled by strikes. A riot at Rowley, Mass., May, 1840, began among railroad laborers in consequence of deduction of pay for being late. In 1847 a strike of 1200 journeymen tailors in Philadelphia lasted four months, and obtained the desired advance; in 1848 one of factory operatives at Allegheny City and elsewhere, after eight weeks' idleness and much rioting, secured the adoption of the ten-hour system with a reduction of 16 per cent. in wages. A strike in the mills at Fall River, Mass., 1850-51, kept 1300 persons idle for nearly six months, at a loss in wages of above \$140,000. One of iron-workers at Pittsburgh, 1850, was accompanied with violence; many were

sentenced to fines and imprisonment, but pardoned. Salisbury, Mass., was much injured in 1852 by a strike of the mill-hands, caused by the abolition of a fifteen minutes' recess for lunch. The Lynn shoe-makers lost \$200,000 in wages by a strike, Feb. 22, 1860. The coal-miners in Western Pennsylvania and elsewhere struck in 1859, and 1862-63. In 1863 strikes were numerous. That of the Pittsburgh stove-moulders in January, 1867, resulted in breaking up their union. The Pennsylvania legislature passed, in 1868, the eight-hour law; non-compliance with it on the part of the Mahanoy valley colliers produced an extensive strike in that region; the price of coal for many years has been largely affected by movements of this kind. The business of Schuylkill county was greatly injured by the contest of 1870, the miners refusing to accept the basis of \$2 per ton and then that of \$2.50, fixed by the firms, and successfully demanding \$3. During this year there was much trouble in the shoe-shops of Massachusetts, and Chinamen were introduced at North Adams. In January, 1871, a strike of miners began at Scranton, which extended throughout the whole anthracite field; it was settled by arbitration in May, but further increase of wages was gained in the fall.

The famous railroad strikes of 1877, which were attended by gross violence, immense destruction of property, and considerable loss of life, began at Martinsburg, W. Va., on the Baltimore & Ohio R. R., and extended to the Pennsylvania Central, the Erie, and many other roads. The lawless element of the community joined the strikers, and large mobs for a time had their own way at Pittsburgh and elsewhere; the militia in some cases refused to act, and in others were worsted. The loss at Pittsburgh, July 21-23, was estimated at \$5,000,000, \$2,000,000 of which was borne by the railroad; some 1600 cars with their contents, 126 locomotives, and nearly all the shops were burned, and much property stolen; traffic and travel were interrupted for a week. Disorders occurred somewhat later at Reading, Scranton, and other towns, as also at St. Louis and several places in Ohio.

These acts of violence, the destruction of the property of railroad companies and other employers, and the odious terrorizing and compulsion practised on men who wish to work, are frequent accompaniments of strikes, rather than properly a part of them; but they must be expected and reckoned with in considering the subject.

Volume XX. of the Tenth U. S. Census reports the strikes and lock outs of the year 1880 as numbering 762, of which 304 were in Pennsylvania, 104 in New York, and 93 in Ohio. Five hundred and twenty-four affected mechanical and manufacturing industries, 182 mining, and 50 trade and transportation. In estimating 813 causes and results, Mr. J. D. Weeks assigns 539 strikes to questions of wages and 71 to other difficulties: of 85 lock-outs, 78 related to wages; 118 causes were unclassified or mixed. Of the strikes 143 were successful, 70 were compromised, 156 failed, and 241 were not reported; of the lock-outs, the corresponding numbers were severally 10, 8, 34, and 33; of the cases unclassified, 16, 7, 37, and 58. The strikes in the mining region of Ohio, 1869-80, which attracted great attention, and frequently required the help of the militia to enforce the law, have been discussed by the Ohio bureau of labor statistics. The whole number of strikes and lock-outs recorded in the United States prior to 1881 is estimated at 1491, of which 1089 related to wages: 316 succeeded, 154 were compromised, 583 failed, and the result of 438 is unknown.

The statistics of this subject from 1881 to 1886 are very fully presented in the *Third Annual Report of the Commissioner of Labor* (1888). In 1881 2928 es-

establishments were affected by strikes, in 1882, 2105; in 1883, 2759; in 1884, 2367; in 1885, 2284; in 1886, no less than 9861. In every case the majority of these were closed, the average being 23 days. In these six years the aggregate of idle days was 487,615, with a loss to 1,660,835 employees of \$51,814,723, and to employers of over \$30,000,000. Very many of the old hands lost their work, and 37,483 were brought from other places. Nearly four-fifths of the strikes were ordered by labor organizations; over 10,000 succeeded, about 3000 won partial success, and nearly 9000 failed. New York was the State most largely affected; after it came Pennsylvania, Illinois, Connecticut, Ohio, Massachusetts, and Texas—judging by the number of persons involved; looked at from other points of view, the order differs somewhat. The chief industries concerned were building trades, 6075 houses; tobacco, 2959; mining, 2060; clothing, 1728; metals and metallic goods, 1570; transportation, 1478; food preparations, 1419. The lock-outs for the same years numbered 2214, of which 1753 were ordered by organization. About 564 of them succeeded and 190 in part, while 1339 failed. One thousand six hundred and twenty-five establishments were closed for an average of 28.4 days, with a loss to employers of \$3,462,261, and to employees of \$8,157,717. The proportion borne by the year 1886 in these totals is even greater than with the strikes.

The figures for New York during 1887 are given in the *Fifth Annual Report* of the State Bureau of Statistics for Labor. In that year strikes affected 1604 shops, including 144 trades and callings. Of these attempts 694 succeeded, 696 failed, 190 were compromised, 424 were yet pending. The number of workmen engaged was 51,731, only about two-fifths that of 1886; but the number to whom employment was afterward refused was greater, being 8176 as against 6391. The loss of wages was over \$2,000,000, and \$217,069 was spent by the labor organizations in aid to the strikers. Employers lost over \$1,100,000, and 11,472 persons acquired an increase of wages estimated at \$944,632. As to the causes of the strikes (which here include lock-outs also), 469, or only about 34 per cent., were for increase of wages; 158 were for a reduction of the hours of labor; 118 were due to refusals to handle boycotted coal or freight; 113 to the employment of non union men, and 11 to the discharge of members of the unions. The boycott showed an increase, 242 cases against 186 in 1886; of these 101 were professedly successful, 36 failed, and 105 were yet pending.

Bradstreet's report gives nearly 1000 strikes as occurring in the United States from Jan. 1, 1887, to April 1, 1888, 834 of which were in 1887—this number indicating movements, and not establishments affected, as in the N. Y. report above cited. Some 340,854 workers struck during 1887. Of these strikes, the most recent as to which statistics are available, it is instructive to note the more important. The year 1887 began with a strike of 2000 brewers in Philadelphia to resist a reduced schedule of wages; after four months it was partially successful. It was directed by a combination of local unions under the guidance of the Knights of Labor, from whom, however, the brewers withdrew as soon as their affair was settled. Far more important in its results was the strike of the coal handlers at Bayonne, Perth Amboy, South Amboy, and other places in eastern New Jersey at the same time. It failed after lasting six weeks, but the various associations of coal handlers in New York and Brooklyn followed, seeking a higher and uniform rate of wages. James E. Quinn, of District Assembly 49, assumed the leadership of the movement, instigated a series of sympathetic strikes, interrupted the movement of coal to New York so seriously that a coal famine was threatened, and called

out all the men connected with work on the wharves. Of these—longshoremen, boatmen, grain handlers, coal handlers, bag sawers, grain sealers, coal-train brakemen, etc.—in New York, Brooklyn, and Jersey City, including the employees of the Dominion Steamship line, some 23,000 belonged to the several local assemblies, and 15,000 of them obeyed the call. The corporations resisted this effort to paralyze their trade, used strenuous efforts to procure new laborers, and employed a great number of Pinkerton detectives to protect these and the property about the wharves and tracks. Collisions occurred, and for several weeks the strike was the object of universal attention and wide anxiety. Quinn threatened and attempted likewise to affect the gas and electric light companies, the machine shops, breweries, etc., and practically to suspend all business in New York. He undertook too much; most of the local assemblies refused to obey. Then he tried, with but partial and temporary success, to call off the employees of the coal carrying roads terminating in and about Jersey City, and finally to paralyze the coal trade in New England and elsewhere. The main strike ended before the middle of February, having substantially failed some time previous. Bradstreet's estimates that above 34,000 men were engaged in it, with a loss in wages of \$2,650,000; the official figures of New York are 6574 men, and a loss of over \$400,000 in that State.—The drivers and conductors of the Consolidated Street Car Co. in Boston, offended by a new rule to pay them by the trip instead of by the day, struck, Jan. 11: they were members of District 30, K. of L., but acted independently of the Assembly. Public sympathy was with the men, and they won a complete victory in a single day.

A strike which began about this time among the shoe factories in Worcester Co., Mass., was turned into a lock-out by a combination of the employers, who refused to employ union men or to treat except with individuals. After five months the men, numbering 8000, were entirely defeated, with a loss in wages of \$2,500,000. The strike was directed by the leaders of District Assembly 30, the funds of which were largely expended in aid; but the strikers were dissatisfied, and ultimately withdrew and formed an Assembly of their own, K. of L. Toward the end of January 2400 employees of the Higgins carpet factory, in New York, struck against a proposed reduction of 10 per cent. in their wages; a compromise was effected after four days. In February they went out again, at the instigation of District Assembly 49, to aid the coal handlers, but two weeks' idleness resulted in a failure. Early in April, 7500 of the 8000 carpenters in Chicago, members of the local Trades Assembly, struck for fewer hours and more pay. The K. of L., to whom one-fourth of them belonged, interfered as "peacemakers," but the unions won a victory in a fortnight. Similar strikes of trades unions were induced by this success; in Cincinnati 1100 men were idle a week, and in Brooklyn 800 won after ten days. In April several movements of stove-moulders against certain boycotted patterns were merged into a general strike by the Amalgamated Association of Iron and Steel Workers; 3311 men in Chicago, Milwaukee, Keokuk, Quincy, Pittsburgh, and elsewhere were affected, and won after being out from six to eight weeks. Early in May 5000 hod-carriers of Chicago struck, with the authority of the Trades Assembly. The result was complicated, and led to a combination and lock-out of the employers, whose terms were so severe (including a boycott on their men) as to suspend all building operations, and throw 15,000 men out of work. After nine weeks the workmen yielded. In May, 5000 shoemakers in Haverhill, Mass., and 2600 in Cincinnati, were locked out because of disputes as to wages; compromises were effected, speed-

ily in the former case, in the latter after a month. During the spring a strike of 13,000 coke-workers in the neighborhood of Pittsburgh, members of the K. of L., failed after ten weeks, with a loss in wages of nearly \$1,000,000. Mr. Powderly condemned this strike as unauthorized. In May, 2000 brickmakers in Pittsburgh lost a week and gained nothing. In June, 1200 carpenters of St. Paul and Minneapolis were idle nine weeks under authority of a trades union; the matter was compromised. In July, 4000 operatives of the Harmony Mills, at Cohoes, N. Y., struck for higher wages under direction of local leaders of the K. of L., who prolonged the struggle for two months by sending many of the hands to work elsewhere; the mills procured new operatives, and the strike failed. During the first half of 1887 *Bradstreet's* reckons 607 strikes, involving a greater number of workmen than the corresponding period of 1886. The failure of two-thirds of these movements caused a diminution in the following months. July 11, 106 engineers and firemen of the Brooklyn Elevated Road struck, giving but an hour's notice; their places were speedily filled, and the Brotherhood of Locomotive Engineers was signally defeated. In August, 2500 men in the rolling mills of Pittsburgh struck because of an alleged violation of a rule; after a month they won their point. A similar contest began shortly after at Youngstown, O., involving 3500 men, who were successful after a fortnight. At the same time 2500 miners in the Hocking Valley, O., struck for a semi-monthly pay-day, and won in two days. In that month at Brockton, Mass., W. L. Douglas, a State senator and active member of the K. of L., locked out the workmen in his shoe-factory for resisting the use of labor-saving machines, dismissed the Knights in his employ, and made his shops "free," having therein the support of local public opinion. In August and September, 1100 cotton spinners at Fall River were out five weeks, and then accepted a compromise. Sept. 13, 1000 cigarmakers struck on a question of apprentices, and were defeated after nine days. A similar difficulty kept over 2000 glass blowers, in various factories in the East, out of work for a month or more, and was generally settled by a compromise; the usual result was a return from the K. of L. to the trades union. A very extensive and disastrous K. of L. strike among the Pennsylvania coal miners of the Shamokin, Mahanoy, Lehigh Valley, and other districts began, Sept. 10, lasted till January, 1888, and involved some 27,000 men, whose efforts to gain an increase of pay resulted in an estimated loss of \$2,500,000 in wages. In October the brass-workers of Brooklyn struck for a Saturday half-holiday without loss of pay, claiming that their employers had broken an agreement; they were locked out, and defeated after a month of idleness. At the same time the ale brewers and book printers of New York struck; the latter demanded increased pay, a regulation of the apprentice question, and the turning of every office into a union or "card" place. Their typographical unions, backed by the Central Labor Union, were opposed by the employers, who organized as "Typothetæ." After three weeks a compromise was effected, the first claim being granted and the last denied. In October and November, 500 shoemakers were locked out for five weeks in Philadelphia, and brought to submission. A similar case occurred in Rochester; a union had attempted to dictate to employers, and 3500 men were locked out through December and half of January, 1888, with the same result.

Near the end of 1887 fears of a coal famine were aroused by an attempt to compel the Reading Railroad to discriminate against firms obnoxious to certain parties, as employing non-union men. The company declined to permit this interference with its business, and the K. of L. called out over 6000 of its

employees on Dec. 24, and threatened to extend the strike to all the coal-carrying roads and coal mines of Pennsylvania. But many of the Knights refused to obey; their authorities declared the strike illegal, and most of those who had taken part in it, having no prospect of support from the general fund, resumed work on the 27th. A smaller attempt on the next day proved equally abortive; but the matter assumed more serious shape in January and February, 1888, through many strikes of coal miners, partly in sympathy with the railroad employees, partly in search of 8 per cent. advance in their own wages. President Corbin of the Reading R. R. was involved in a contest with the Executive Board of the K. of L., which represented and directed the miners in the company's collieries. Ultimately these returned to work at the old rates. The losses were estimated at no less than \$3,620,000 in wages to full 30,000 men, \$1,000,000 to the company, and \$700,000 to consumers in increased prices of coal, besides considerable sums to private collieries.

An even more momentous and alarming strike, attracting general attention for many weeks, began with the engineers of the Chicago, Burlington, and Quincy Railroad, who sought an adjustment of wages similar to the schedules of other roads. For a time trade was nearly paralyzed in portions of the West, gross disorders were perpetrated at points far apart, and lawless confusion seemed to triumph. The affair is too recent for an accurate estimate of what it cost the country.

Of the 884 strikes commenced in 1887, 247 were successful, and 115 partially so: these two classes concerned 128,234 employees, or 38 per cent. of all—nearly twice the proportion of 1886. Of them all, 542, or 63 per cent., were for increased wages or a shorter day's work; 225, or 26 per cent., came from trades union demands of other kinds; 68, or 8 per cent., were "sympathetic strikes;" the small remainder is unclassified. Pennsylvania and New York were most affected, with 111,317 strikers and 62,656, respectively. The trades chiefly concerned were coal and coke, with 70,450 men; transportation, 62,379; building trades, 56,560; iron and steel, 29,989; leather, shoes, etc., 28,805; textiles, clothing, etc., 25,328; patterns and machinery, 10,000; tobacco, 8,000. The building trades lost the greatest number of days, 1,492,078: boots and shoes follow, with 1,291,943. The entire number of days during 1887 employed in successful strikes was 1,774,694, while 5,081,315 were thrown away on failures. Some 3,000,000 days must be added for strikes still in progress at the end of the year, making 10,000,000, or about a month for each, of near 350,000 strikers. If these earned an average of \$1.50 a day when at work, the total loss in wages for 1887 would be some \$13,500,000. The loss to business interests in general, and to consumers in increased prices of goods, cannot be estimated with any degree of accuracy.

It cannot be said that strikes are never beneficial to the striker: the figures prove the contrary. More than this, the fact that they are frequent and always possible may go far to check the rapacity of some employers, and to win respect for the hand that wields so dangerous a weapon; yet it seems as if civilization might have devised some less cumbrous and costly method of coming to an understanding. The problem is more difficult in an ethical than in an economical view. Under free institutions the right of the workman to better his condition if he can, and to combine in order to that end, is unquestionable; and no less so the right of the employer to manage his business in his own way, and to employ such persons and under such regulations as he sees fit. The natural jealousy between Labor and Capital tends to make each careless of the other's interests and claims: employees have sometimes de-

manded increased wages at a time when the business was being conducted with little profit or actual loss, so that increased expenses would have meant ruin; and employers have often regarded their workmen as machines, and neglected or refused to allow them any share in the great profits of a fortunate season. Greater mutual consideration and consequent harmony may come through the advance of education, intelligence, and character; and a definite remedy has been found (when ever wisely tried) in co-operative schemes, which make the operative a partner, however humble, and no longer a mere instrument. Short of this happy climax, which requires largeness of mind if not benevolence in the capitalist, legislation must strive more and more to suppress those aggressions, alike on public welfare and on personal liberty, which cannot be tolerated in a free state. The tyrannies of dictation and the enormities of the boycott, from whatever quarter and in whatever interest, must be restrained. The abuse of power, whether by walking delegates or by wealthy corporations, is alike incongruous with American ideas. The constant liability to sudden stoppage of the wheels of modern life, of railroad and telegraph and traffic, by whatever means it is to be averted, cannot be endured much longer. Strikes, lock-outs, and their accompaniments, are the rude resources of an incomplete civilization. (F. M. B.)

STRINGHAM, SILAS HORTON (1798-1876), admiral, was born at Middletown, N. Y., Nov. 7, 1798. Entering the navy as midshipman in 1809, he took part in the engagement of the frigate *President* with the *Little Belt*, and was made lieutenant in 1814. He served in the Algerine war, and afterward along the Slave coast of Africa. In 1821 he was engaged in suppression of piracy in the West Indies. He rose to be captain in 1841, and in the Mexican war took part in the bombardment of Vera Cruz. In 1853 he took command of the Mediterranean fleet, and afterward was in charge of the Boston navy-yard until the civil war broke out. He was then summoned to Washington to advise the government in regard to naval affairs. He was placed in command of the North Atlantic blockading fleet and conducted an expedition to Hatteras Inlet, where two forts surrendered after bombardment, Aug. 29, 1861. Retiring from active service in the following December, he resumed his command of the Boston navy-yard. In 1862 he was promoted rear-admiral on the retired list, and in 1870 was made port-admiral of New York. He died at Brooklyn, Feb. 7, 1876.

STRONG, GEORGE CROCKETT, a soldier in the civil war, was born, Oct. 16, 1832, in Stockbridge, Vt. His father dying while he was a child, he was brought up by an uncle, A. L. Strong, Northampton, Mass. He entered West Point Military Academy and was graduated in 1857, and assigned to the ordnance with the brevet rank of 2d lieutenant. In 1859 he was promoted to 2d lieutenant, and became assistant at Watervliet arsenal, West Troy, rising to the command in 1861, when he became 1st lieutenant. On the outbreak of the civil war he sought active service, and was on the staff of Gen. McDowell as ordnance officer at the first battle of Bull Run, and afterward served in the same capacity on the staff of Gen. McClellan. He had in October, 1861, been appointed assistant adjutant-general of volunteers, with the rank of major, and was engaged in the organization of the New Orleans expedition, which he accompanied. In April, 1862, he commanded the expedition from Ship Island to Biloxi, Miss., and in September led the successful expedition to Pontchartroula, where he destroyed a large train and broke up Jeff. Thompson's headquarters. In November, 1862, he was made brigadier-general of volunteers and became Butler's chief of staff, but in December he was compelled to withdraw on sick

leave to New York, where he remained till June, 1863, having been commissioned captain of ordnance in the previous March. He commanded a brigade in the operations against Charleston, S. C., and led the successful attack upon Morris island, where he was the first to land. While leading the second assault on Fort Wagner, on July 18, and cheering on the storming column, he was mortally wounded, after having gained the parapet of the fort. He was at once removed to New York City, where he died, July 30, 1863.

STRONG, JAMES, a layman, honorably entitled to the degree of S. T. D., was born in New York City, Aug. 14, 1822. In his youth he began the study of medicine, but after graduating at Wesleyan University, Middletown, in 1844, he became a teacher. His health failing, he became a farmer, and soon was active in improving the village of Flushing, L. I. He had there entered upon a course of Biblical study, and when giving instruction in ancient languages he prepared manuals of their grammar. His first larger work was a *Harmony and Exposition of the Gospels* (1852), originally prepared for the English version, and afterward adapted to the Greek. In 1856 he received the degree of S. T. D., and from 1858 to 1861 he was professor of Biblical literature in Troy University. His series of *Lessons for Every Sunday in the Year*, in which he was aided by other writers, was the precursor and model of the International Sunday school series. In 1868 Dr. Strong was made professor of exegetical theology in Drew Seminary at Madison, N. J. He took part in the revision of the English Old Testament. In company with Rev. Dr. John McClintock he prepared the well-known *Cyclopædia of Biblical, Theological, and Ecclesiastical Literature* (10 vols., 1867-79). He also edited Daniel in Schaff's edition of *Lange's Commentary*, and some other Biblical works.

STROSSMAYER, JOSEPH GEORGE, Croatian archbishop, was born at Essek in Slavonia, Austria, Feb. 4, 1815. He was educated at the University of Pesth, obtained the degrees of doctor of philosophy and of theology, and, after having spent some time in the Augustinian convent at Vienna, was ordained priest in 1838. He was soon made professor in the seminary at Diakovar, then court-chaplain, and in 1849 was consecrated bishop. His diocese extended over Croatia and Servia, and he became the head of the Croatian national party in opposition to the Hungarians. Primary instruction was fostered, a seminary established for Bosnians, and a university opened at Agram. Here also an academy was instituted, with a fine gallery of paintings on national subjects and by native artists. A handsome cathedral was erected at Diakovar, and at Rome Archbishop Strossmayer caused the ancient Illyrian chapel of San Girolamo to be restored. In the Austrian Reichsrath, to which he was elected in 1860, the archbishop favored a federal union of the various nations and races composing the empire. The Croatian leaders, finding themselves unable to secure home-rule, accepted the compromise offered by the Hungarians giving the Slavonic people representation in the Hungarian diet, and Strossmayer then withdrew from political affairs. At the Vatican Council in 1870 he made open and strenuous resistance to the promulgation of the doctrine of papal infallibility, and finally left Rome without accepting the dogma. Even in a later visit to the Holy See he persisted in his attitude of ignoring the action of the council. In his efforts to preserve and advance the Croatian national spirit Strossmayer has published many historical and popular works. The most important is *Monumenta Slavonorum meridionalium* (Rome, 1863). For an interesting sketch of this "Father of his People," see Laveleye's *Balkan Peninsula* (1887).

STROTHER, DAVID HUNTER (1816-1888), artist, author, and soldier of the civil war, born at Martinsburg, Va. (now W. Va.), Sept. 26, 1816. He studied drawing in Philadelphia, and afterward, under Samuel F. B. Morse, in New York. After travelling in the Western States he went, in 1840, to Europe, where he remained 5 years. On his return, in 1845, he studied in New York the art of drawing on wood for engravers, and illustrated some books. From 1852 to 1861 he contributed to *Harper's Magazine*, under the name "Porte Crayon," a series of illustrated articles, chiefly on Virginia and the South, some of which appeared in book-form under the title of *Black Water and Virginia Illustrated*. On the outbreak of the civil war he volunteered into the United States service, and was appointed captain and assistant adjutant-general, rising to the colonelcy of the Third West Virginia Cavalry. In 1864 he resigned, and in 1865 was brevetted brigadier-general "for meritorious services." He returned to his home at Berkeley Springs, where for some years he continued to supply sketches to the magazines. In 1879 he was appointed consul-general to Mexico, and held the office till 1885. He died at Charleston, W. Va., March 8, 1888.

STRUVE, OTTO WILHELM, Russian astronomer, was born at Dorpat, Russia, May 7, 1819. There his father, Dr. Wilhelm Struve, became pre-eminent through his researches on double stars, and, by his influence with the Emperor Nicholas, brought about the erection of the Pulkowa Observatory in 1840. As assistant to his father Otto made a catalogue of many hundred double stars, before unknown as such. His work determining the constant of precession, popularly called the annual amount of motion of the equinox among the stars, won the gold medal of the Royal Astronomical Society in 1850. He has determined the parallax of several stars, made a series of observations on the rings of Saturn, has observed several solar eclipses, and had general charge of the geodetic operations in the Russian Empire. In 1862 he succeeded his father as director of the observatory. In 1879, acting under the authority of the Russian government, he contracted for a larger refractor than any yet made; with Alvan Clark & Sons, of Cambridge, Mass., for a 30 inch object-glass; and with Repsolds, of Hamburg, for the mounting. This telescope has been in operation since 1885. (See **OBSERVATORIES and TELESCOPES**, in the **ENCYCLOPEDIA BRITANNICA**.) Otto Struve's greatest work, the result of thirty-five years' observations of the double stars, was published in 1878, in the ninth volume of the *Pulkowa Observations*.

STUART, GEORGE HAY, president of the U. S. Christian Commission during the civil war, was born at Rose Hall, county Down, Ireland, April 2, 1816. In early manhood he emigrated to America, and settled in Philadelphia, entering into mercantile life. He was active in forming the Young Men's Christian Association of that city, and was for many years its president. He also assisted in the national and international organization of these associations. This work, bringing him into contact with representative Christian men of all parts of the country, was a fitting preparation for the work of the Christian Commission, which he undertook when the officers of the Sanitary Commission refused to become agents of funds for ministering to the religious needs of the soldiers. The great work thus neglected was energetically taken up by Mr. Stuart, and successfully carried through. His labors won the approval of General Grant, and of nearly all the Union generals. After the war Mr. Stuart took up more urgently the cause of Christian union, and in 1867 called and presided over a convention in Philadelphia of delegates from all branches of the Presbyterian Church, to consider a plan of union. Though this convention did not

succeed in its grand purpose, it certainly prepared the way for the reunion of the Old and New School branches, effected in 1870. Mr. Stuart, however, had still remained an elder in the Reformed Presbyterian, and was subsequently suspended from his office by a synod of that denomination for a technical offence. The sentence, however, remained inoperative, and Mr. Stuart, with the congregation to which he belonged, eventually joined the Presbyterian Church in 1880. He had always been prominent in every movement for the promotion and extension of Christianity, and was an officer in many societies for such purpose. While a merchant he was vice-president of the Mechanics' Bank, and in 1880 he became president of the newly formed Merchants' Bank. His labors had often been interrupted by severe attacks of asthma, and in 1888 he was obliged to retire from business.

STUART, JAMES EWELL BROWN (1833-1864), a Confederate cavalry officer, was born in Patrick Co., Virginia, Feb. 6, 1833, his grandfather having been an officer in the war of the Revolution and his father in that of 1812. After spending two years at Emory and Henry College, Salem, Va., he entered the U. S. Military Academy, whence he graduated in 1854. At both institutions he was noted for his deep religious convictions. On leaving West Point he joined, as 2d lieutenant, the regiment of mounted riflemen then stationed in Texas, and did good service against the Apaches. Next year he was transferred, with the same rank, to the First U. S. Cavalry, which was on duty in Kansas during the border troubles. In this year, also, he married the daughter of Col. Philip St. George, and next month was promoted 1st lieutenant. In 1857 his regiment was engaged in Indian warfare, and he was wounded in an action with the Cheyennes on Solomon's River. Being in Washington in the close of 1859, he volunteered as aide to Lieut.-Col. Robert E. Lee, in his expedition to Harper's Ferry to quell the John Brown insurrection, and identified its leader as "Osawatimie Brown," whom he had known in Kansas. Thereafter he rejoined his regiment, but, obtaining leave of absence in March, 1861, he returned to Virginia, and on the secession of that State resigned his commission. The State authorities forthwith appointed him lieutenant-colonel of Virginia infantry, and, in July, colonel of cavalry. His first active service in his new sphere was in screening the movements of Gen. Joseph E. Johnston from Gen. Robert Patterson when he advanced from Winchester with re-inforcements for Gen. Beauregard on the eve of the battle of Bull Run. In this fight Col. Stuart greatly distinguished himself by his effective defence of Gen. Jackson's left flank, repulsing the assaulting Union force, and thereby contributing no little to the Confederate victory. For his conduct here, as well as for other services, he was in September, 1861, appointed brigadier-general. In the Virginia peninsular campaign he covered Gen. Jos. E. Johnston's rear in his retirement from Yorktown and Williamsburg. In June, 1862, he was directed by Gen. R. E. Lee (to whom the command of the troops for the defence of Richmond had now fallen) to make a raid round the rear of McClellan's army, now lying on the Chickahominy, inflicting as much damage on it as possible, and determining the position of its left. On June 12th he sallied out of the Confederate lines before Richmond at the head of 1200 men and some light artillery, and in the course of three days passed entirely around the Army of the Potomac, destroying a large amount of stores at Tunstall's Station near McClellan's base of supplies at the White House, recrossing the Chickahominy by a ruined bridge, and returning up the James to Richmond, with McClellan's forces on his one flank and the Union gun-boats on

the other. He brought back with him 165 prisoners and his own corps entire (save one man), and, at the same time, information that enabled Lee to make a successful assault on the Union right wing at Gaines' Mill on the 27th. For this brilliant achievement and his services in the Seven Days' fight he was in July—though not yet 30 years of age—promoted to major-general. Soon thereafter he marched north to support "Stonewall" Jackson in his operations against Gen. John Pope, then in command of the Army of Virginia. On Aug. 22 he crossed the Rappahannock, penetrated Pope's encampment at Catlett's Station, captured his despatch-book and baggage, and made prisoners of several officers of his staff. Two days later he was ranking officer in the attack on Manassas Junction, and sent into the town a brigade of infantry, under Brig.-Gen. Trimble, that made many prisoners and captured valuable stores. At the second Bull Run fight he rendered important service by guiding Longstreet to an effective junction with Jackson that resulted in Pope's army being driven back upon Washington. In the ensuing Maryland campaign he led the advance of Jackson's corps, and rendered efficient service at South Mountain and Antietam. Next October (9-12) he made a daring raid across the Potomac, at the head of 1800 picked troops, on Chambersburg, Pa., where he destroyed property to the value of \$250,000 and carried off much booty, the entire cavalry force of the Army of the Potomac being wearied out in pursuing him. He took part in the battle of Fredericksburg, being on guard on the extreme left of the Confederate line. His next noteworthy exploit was a raid on Dumfries, in which, by means of spurious telegrams to Washington, he learned the movements in contemplation by the leaders of the Union forces. In March, 1863, a portion of his force was successfully attacked at Kelly's Ford by the National cavalry under Gen. Averell. At the battle of Chancellorsville his cavalry covered "Stonewall" Jackson's advance to the right of the Union line, and when that distinguished soldier fell, mortally wounded, the command of his corps devolved temporarily on Stuart, who not only extricated it from the critical position into which it had been carried in the darkness, but next day renewed the attack, and, pushing onward, joined the right wing under Lee at Chancellorsville, then abandoned by Hooker. In the succeeding Gettysburg campaign he was sent forward to guard the flanks of Lee's advancing columns, and had several encounters with the enemy, with varying success, as at Fleetwood Hill, Stevensburg, Aldie, Middleburg, and Upperville. At the passage of the Potomac he received permission to repeat his favorite tactical movement of passing behind the enemy's rear, and accordingly crossed the river between the Union army and Washington. The detour was wider than had been calculated on, and he did not reach Gettysburg till the evening of the second day of that eventful conflict (July 2), and so was in time only to take part in the closing struggle and to cover the rear of the retreating Confederates by guarding the gaps of the mountains. This raid, which deprived Lee of his cavalry at a most important crisis for the Southern cause, has been much criticised, the responsibility for it being especially the subject of controversy. When the Confederates lay intrenched on the northern bank of the Potomac, Stuart's cavalry had many conflicts with those of Gens. Judson Kirkpatrick and John Buford, as well as, later in the summer, with those of the above generals and of Gens. Alfred Pleasanton and Henry E. Davies, when holding the line of the Rappahannock. When Grant entered the Wilderness in May, 1864, his chief of cavalry, Philip H. Sheridan, at the head of 12,000 troopers, advanced on Richmond. Stuart in-

stantly hurried to interpose between him and the city, concentrating his force at Yellow Tavern. Here a desperately contested fight took place, in which Gen. Stuart was mortally wounded and his men routed. He died at Richmond, May 12, 1864. Till Sheridan came on the field to contest the palm with him, Stuart was undoubtedly the foremost cavalry commander in either army. The novelty, boldness, and rapidity of his movements—in a word, their dash and brilliancy—combined with their general success, invested him with a halo of romance, and brought him to be regarded as the Rupert of the South. (J. H.)

STUART, MOSES (1780-1852), Hebraist and Biblical theologian, was born at Wilton, Conn., March 26, 1780. At twelve he read Edwards on *The Freedom of the Will*, and at fourteen mastered the Latin grammar in three days. Entering Yale as a sophomore, he graduated in 1799, taught school for two years at North Fairfield and Danbury, studied law, and, just before his admission to the bar, 1802, was appointed tutor at Yale. Here he remained two years, studying theology with Pres. Dwight, till licensed to preach by the New Haven Association, 1804. On March 5, 1806, he was ordained pastor of the First Church in New Haven. After nearly four years' eminently successful ministry, he resigned his charge to become professor of sacred literature at Andover, Feb. 28, 1810. His first publication was a Hebrew grammar without points (1813), printed largely by his own hands, and previously used in MS. by his students, who copied the sheets as fast as he wrote them. Though many lamented his withdrawal from the pulpit, he was invaluable in the professor's chair, which he retained till 1848. Of his students over 1500 became ministers of the gospel, over 70 college presidents or professors, and over 100 foreign missionaries, of whom 30 translated the Bible into foreign languages. On these he exerted a powerful influence, and so stimulated zeal and enlarged facilities for study in his department as to earn the title of "Father of Biblical literature" in America. His principal publications were *Letters to Channing* (1819, six editions); *Grammar of the Hebrew Language*, with points (1821), highly commended at Oxford; *Letters to Samuel Miller, D.D. on the Eternal Generation of the Son of God* (1822); a translation of Winer's *New Testament Grammar*, with Prof. E. Robinson (1825); *Commentary on the Epistle to the Hebrews* (2 vols., 1827-28; 1 vol., 1833); on the *Epistle to the Romans* (2 vols., 1832; 1 vol., 1835); *Hebrew Chrestomathy* (1829); *Principles of Interpretation*, from the Latin of Ernesti (4th ed., 1842); *Grammar of the New Testament Dialect* (2d ed., 1834); *Notes to Hug's Introduction to the New Testament* (1836); *Hints on the Prophecies* (2d ed., 1842); *Critical History and Defence of the Old Testament Canon* (1845); *Commentary on the Apocalypse* (2 vols., 1845); a translation of Rödiger's *Gesenius' Hebrew Grammar* (1846); *Commentaries on Daniel* (1850), *Ecclesiastes* (1851), and *Proverbs* (1852); *Conscience and the Constitution*, called forth by Daniel Webster's speech (1850). Besides these he wrote 14 pamphlets, and some eighty contributions to the *American Biblical Repository*, the *Bibliotheca Sacra*, and other periodicals, amounting to over 3000 octavo pages. He died at Andover, Jan. 4, 1852. Strange to say, he never obtained the degree of D. D., though highly deserving it.

STUBBS, WILLIAM, English bishop and historian, was born at Knaresborough, June 21, 1825. He was educated at Ripon and at Christ Church College, Oxford, graduating in 1848. He was then made fellow of Trinity College, and, being ordained priest, became vicar of Navestock. As the first-fruits of his antiquarian and historical researches, he published in 1858 *Registrum Sacrum Anglicanum*, which,

by its precision of statement and correction of the errors previously abounding in civil and ecclesiastical histories, firmly established his reputation. In 1862, becoming librarian to Archbishop Longley, of Canterbury, he was enabled to pursue still further researches, which resulted in his careful editing of many early English chronicles. In 1866 he was made professor of modern history at the University of Oxford, and in 1869 curator of the Bodleian Library. He published *Select Charters and other Illustrations of English Constitutional History* (1870). All his previous labors led up to his most important work, the *Constitutional History of England in its Origin and Development* (3 vols., 1874-78). His freedom from party spirit and scrupulous fidelity to facts have laid the foundation for a better understanding of English history. In 1875 he was made rector of Cholderton, and in 1879 canon residentiary of St. Paul's. He held this position, together with his professorship at Oxford, until 1884, when he was appointed Bishop of Chester.

STUCKENBERG, JOHN HENRY WILBURN, philosopher, was born at Bramsche, Germany, Jan. 6, 1835. Having emigrated to America in early life, he graduated at Wittenberg College, Ohio, in 1857, afterward studied at German universities, and became pastor of Lutheran churches in Iowa and Pennsylvania. During the civil war he was chaplain of a Pennsylvania regiment for a year. In 1873 he was made professor of theology in Wittenberg College, and in 1880 he went to Berlin, where he was placed in charge of the American Chapel. He assisted Rev. W. L. Gage in translating Hagenbach's *German Rationalism* (1866). He has published, *Ninety five Theses* (1867); *History of the Augsburg Confession* (1869); *Christian Sociology* (1880); *Life of Immanuel Kant* (1882); *Introduction to the Study of Philosophy* (1887).

STURGEON, the largest fresh-water fish of the northern hemisphere, to which it is exclusively confined. The sturgeon belongs to the primitive order of cartilaginous armored fishes known as Ganoids, of which order it is probably the youngest representative, no trace of it having been found beyond the Eocene formation. In conformity with the Ganoids it has free gills, and is more or less covered with bony plates in longitudinal rows, the tail is heterocercal, and the skeleton cartilaginous. The sturgeons constitute a family, *Acipenseridae*, with two genera, of which *Acipenser* is the most impor-

See Vol. XXII.
p. 611 (p. 643
Am. Rep.).

Sturgeon (*Acipenser sturio*).

tant. The common sturgeons of Europe and America were classed as separate species by the older writers, that of America being known as *A. oxyrinchus*, but they differ but little, and are now generally classed together as *A. sturio*. This species is ordinarily about six feet in length, though in rare cases it reaches a length of 18 feet. Its body is long and slender, gradually tapering, and covered throughout by large, bony tubercles. In color it is of a grayish brown above, silvery on the lower sides, and white below. It is found along our coast as far south as Florida, entering the rivers to spawn, during which season it is taken in great numbers. The flesh is white and firm, and affords excellent food, though less used for that purpose in this country

than in Europe. The ova of the sturgeons are very small, yet the ovaries are so large as in some species to make up nearly one-third of the entire fish, so that the number of eggs is enormous. It may equal 3,000,000 for a single female. It is probably due to this fact that the sturgeons remain undiminished in number, despite the vast multitudes that are annually taken in the rivers of Europe and America. In addition to the use of the flesh as food, the roe is employed to make the food-substance called caviare, a favorite viand in Russia. The making of caviare was formerly confined to Europe, but is now carried on somewhat extensively in America, the sturgeon-fisheries of the Hudson and Delaware, for instance, being largely devoted to this industry. Isinglass, which is made from the inner coat of the air-bladders, is another important product of the sturgeon. As an evidence of the extent of the sturgeon-fisheries, it may be stated that more than 200 tons of caviare yearly have been produced from the catch of the rivers flowing into the Caspian Sea.

In addition to *A. sturio*, the Atlantic waters of the United States possess another species, *A. brevirostris*, distinguished from the former by its shorter and blunter nose. It is less abundant, and is not found north of Cape Cod. Both species frequent the rivers and estuaries in great abundance in summer, when they may be frequently seen leaping from the water. They spawn in the lower stretches of the rivers, and partly in the brackish water at their mouths, where they seem to obtain food by grubbing in the mud for its living creatures. Within a few years the taking of the sturgeon for smoking and the manufacture of caviare has attained considerable importance in several of the larger rivers flowing into the Atlantic.

The Pacific coast also has two species, *A. transmontanus* and *A. medirostris*. The former of these, known as the "white sturgeon," is a large species, attaining a length of 8 feet or more and a weight of 400 or 500 lbs., though seldom found of over 150 lbs. weight. It abounds in the Sacramento, Columbia, and Frazer rivers, ascending them at the same time as the salmon, and is an important food-fish in the San Francisco markets, where it is always abundant and very cheap. It is little used as food in its fresh state elsewhere, on account of the abundance of salmon, but is smoked, and caviare made of its roe. *A. medirostris*, the "green sturgeon," is of the same size and distribution as the "white," but is much less abundant, and is not used for food, being reputed to be poisonous.

Another species of considerable commercial importance, *A. rubicundus*, has its home in the Great Lakes, and in the Mississippi and its tributaries. It is particularly abundant in the upper lakes, of which it is the largest fish, though much smaller than the other species named. Its extreme weight is 100 lbs., and its average length less than 5 feet, though there are traditions of 9-foot sturgeon having been taken. It lives on the shell-fish of the lakes, spawns in the early summer months, and is caught in great quantities, the fishery lasting from September 10th to the middle of October. It is not popular as a food-fish, though palatable when properly cooked, but its flesh is pickled and smoked in considerable quantity, and much caviare made from its eggs. This is done by pressing them through a sieve till they are free from all particles of membrane, and then putting them into salt pickle.

The second genus of sturgeons, *Scaphyrhynchus*, differs from that described in several particulars, principal of which are the lack of spiracles, and the confluence of the osseous bucklers on the tail, which they entirely cover. Four species are known, all exclusively fresh water in their habitat. America possesses *S. platyrhynchus*, which inhabits the Missis-

issippi and other southern rivers, and attains a length of 5 feet. It is not highly valued as a food-fish. Large as are some of our American sturgeons, they are surpassed in size by certain species of Europe. One species of the river-systems of the Black and Caspian seas is said to sometimes attain a length of 20 to 25 feet, and a weight of nearly 3000 lbs. (C. M.)

STURGIS, SAMUEL DAVIS, general, was born at Shippensburg, Pa., June 11, 1822. Entering the U. S. Military Academy in 1842, he was graduated and promoted as 2d lieutenant, Second Dragoons, in 1846. During his service in Mexico he was captured near Buena Vista, February 20, 1847, two days before the battle, and was not released until eight days after. He served after the Mexican war at Jefferson Barracks and Fort Leavenworth, and engaged in Indian warfare from 1854 to 1857, especially with the Apaches, and was promoted to captain, First Cavalry, in 1855. He continued on frontier duty until the opening of the civil war, and became major of the First Cavalry, in August, 1861. He was distinguished in the battles of Dug Spring, Mo., and of Wilson's Creek in August, 1861, under Gen. Nathaniel Lyon, whom he succeeded in the command when that general fell. He received the brevet of lieutenant-colonel for services in those battles, and was made brigadier-general of volunteers, Aug. 10, 1861. He was in command of the defenses of Washington from May to August, 1862, fought in the second battle of Bull Run, Aug. 29, 1862, and was with the Army of the Potomac at South Mountain, and at the battle of Antietam. In the battle of Fredericksburg, Dec. 13, 1862, he commanded the second division of the Ninth Army Corps, and for his conduct there was brevetted colonel. Constantly active in military operations, he was promoted to lieutenant-colonel in October, 1863, and took part in the military operations in East Tennessee, in the fall of that year and the beginning of the next. Here his restless activity found abundant occupation, especially in conflict with Gen. N. B. Forrest, against whom he was successful. At the close of the war he was brevetted major-general in the regular army. He was mustered out of the volunteer service in August, 1865, and was thereafter engaged on frontier duty, becoming the colonel of the Seventh Cavalry in May, 1869. He served as superintendent of the recruiting service in St. Louis in 1874, and commanded on the Yellowstone expedition from May to October, 1877. He was placed on the retired list of the army on June 18, 1886. (H. C.)

STUYVESANT, PETER, director-general of the New Netherlands, was born in Holland in 1602, his father being a Frisian clergyman. He served in the West Indies, was director of Curaçoa, lost a leg in an attack on the Portuguese island of St. Martin, and then returned to Holland. The Dutch West India Company next appointed him director-general of the New Netherlands, where he arrived in 1647, forthwith establishing a court of justice and, in deference to the popular will, ordering a general election of 18 delegates, from whom he selected his advisory council. Toward the Indians, whom his predecessor, William Kieft, had provoked to hostilities, he adopted a policy of conciliation, and earnestly endeavored to improve their condition as well as that of the colonists generally, by the introduction of well-meant reforms. He prohibited the sale of liquor as well as of fire arms to the savages, enforced a rigid observance of Sunday, erected a better class of houses and taverns, founded a public school, and established a market and annual cattle fair. In 1650 he met the New England commissioners at Hartford, and with them arranged a line of partition between the Dutch and English territories, which had been hitherto in dispute. His conduct of the

arrangement, however, was not satisfactory to the Dutch, who declared he "had ceded away territory enough to found fifty colonies, each fifty miles square." In 1651 the Dutch built Fort Casimir, on the Delaware River (then called the South River in contradistinction to the Hudson or North River), which the Swedes claimed to be an encroachment on their rights, and, under their governor, Rising, captured the fort in 1654. Next year Stuyvesant sailed up the Delaware, with 7 vessels and 600 or 700 men, and took possession of the whole settlement of New Sweden. For the next ten years there was unbroken peace on the exterior, but discontent began to show itself at home. In 1653 a convention of two delegates from each village in the colony demanded that "no new laws shall be enacted but with the consent of the people; that none shall be appointed to office but with the approbation of the people; that obscure and obsolete laws shall never be revived." Stuyvesant indignantly ordered the convention to disperse on pain of condign punishment, haughtily replying: "We derive our authority from God and the Company, not from a few ignorant subjects." The embers of discontent, however, continued to smoulder, and encroachments from abroad came to further harass the governor. In 1664 Charles II. granted to his brother, the Duke of York (afterward James II.), all the territory from the Connecticut River to the shores of the Delaware, and four English war-ships, under Captain Richard Nicholls, bearing 450 men, appeared in August in the bay, and demanded the surrender of the city of New Amsterdam. Stuyvesant sent a defiant answer to Nicholls and prepared for resistance. But the municipal authorities, seeing little hope of successful defence and being but indifferently disposed toward their Dutch masters, insisted on yielding, and on Sept. 9, 1664, a treaty was signed at Stuyvesant's house, on his farm or *bowery*, by which the city was surrendered to the English. Its name was forthwith changed to New York, and the designation soon extended to the whole province. Stuyvesant went next year to Holland to report to his superiors, but soon after returned to his farm, whose name still survives in the *Bowery*, New York city. There, in the country, he passed the remaining 18 years of his life, dying in August, 1682. He was buried in the vault of a chapel, belonging to the Reformed Dutch Church, that he had erected on his grounds. Its site is now occupied by St. Mark's Episcopal Church on the corner of Stuyvesant Street and Second Avenue, where his gravestone, bearing an inscription, is to be seen built into the wall. His dwelling-house was destroyed by fire in 1777.

SUGAR. The etymology of the word "sugar" points to a Hindu origin, the form of the word in Sanscrit being *sarkara*, whence it may be traced in differing forms through all the Aryan languages. It is doubtful, however, if all these names originally referred to the same product, since sugar does not appear to have been known in the ancient European world, though it was probably in use from a remote period in India and China. The sweet substance known as sugar is principally of vegetable origin, but occurs to some extent in animals. It is soluble in water, generally crystallizable, neutral to vegetable colors, and is an organic chemical compound of Carbon with Hydrogen and Oxygen in the proportions to form water; that is, 2 parts of Hydrogen to 1 of Oxygen. There are two generically distinct sugars: The Saccharoses or Sucroses, $C_{12}H_{22}O_{11}$; and the Glucoses, $C_6H_{12}O_6$. The latter, which are much less sweet than the former, have been already treated (see GLUCOSE). The former, Saccharose or Sucrose, ordinarily known as Cane-sugar, comprise several varieties, differing in taste and appearance,

though alike in chemical composition. Cane-sugar is found in the stems and roots of many grasses, especially sugar-cane, sorghum and Indian corn; in fleshy roots, as the beet, carrot, turnip, sweet potato, etc.; in the sap of many trees, especially the date-palm and sugar-maple; in most sweet fruits, pumpkins, melons, sweet potatoes, etc.; and in the nectar of flowers and glandular exudations of certain plants. Of the total sugar-product the sugar-cane yields about 60, the beet-root 35, the date-palm 3.5, the sorghum-plant 1.75, and the sugar-maple .5 per cent.

The Sugar-cane, *Saccharum officinarum*, is a kind of gigantic grass, with a solid stem, 1 to 1½ inch thick and 8 to 10 feet high. The stem is jointed at distances of 3 to 6 inches, and sends forth leaves 3 or 4 feet long, which fall with the ripening of the plant. The flower stem, called the "arrow," is 7 or 8 feet high, smooth and jointless, bearing a panicle of soft, silky flowers. The ripe stem contains a pith of dirty-white color and open cellular tissue, which is filled with the saccharine juice of the plant. Numerous varieties of sugar-cane are cultivated, differing much in character, though most botanists think that they all came from one species. Of these varieties those most cultivated in this quarter of the world are the Creole or Madeira (the common sugar-cane), and the Otaheite, a taller variety, whose yield is larger and its juice more easily worked. The Batavian, Chinese, and other varieties are cultivated to some extent. The Salangore is one of the most prolific, and has been known to yield as much as 7200 lbs. of sugar from one acre of canes. The sugar-cane thrives best in warm, moist climates, and finds its most luxuriant development on islands and sea coast regions, perhaps from the moisture of the sea-breezes. It reaches its greatest perfection within the tropics, and cannot be successfully cultivated in frosty regions. Even in Louisiana it is often injured by frost.

The sugar-cane, which had long before been cultivated in the West Indies, was introduced into the United States about the middle of the last century. It is said to have been brought by Jesuits from San Domingo, and cultivated on the banks of the Mississippi, above New Orleans, about 1751. Some authorities say that the first sugar-mill was built on the Mississippi in 1758, and that the culture prospered; but others say that the manufacture of cane-sugar did not begin till 1764, and did not prosper, there being very few sugar-estates in Louisiana when ceded to the United States in 1803. In 1818 25,000 hogsheads of sugar were made. Up to that time the cane was ground by cattle, but steam-grinding was introduced in 1822. The sugar-district at present extends on both sides of the Mississippi, from about 60 miles below New Orleans to nearly 200 miles above, and also along Red river and many bayous. The culture has been introduced into Texas and is increasing in all the Gulf States. Yet in all these States the cane is liable to injury from frosts, which occasionally cause serious reduction of the crop, while droughts and the overflow of rivers also act injuriously. The sugar-cane is exposed to many animal pests, chief among which are rats. These gnaw the standing canes, and let the air into the pith and juice, fermentation and acidity resulting. White ants are also very troublesome in some localities, while there are several borers, plant-lice, etc., which do great injury to the canes. Various more or less effective methods have been introduced to mitigate these pests, the mongoose being employed successfully by some planters to get rid of the rats; while turkeys, insectivorous birds, ichneumon flies, and ants are useful as natural enemies of the boring larvæ.

The cane is propagated only by means of cuttings, no kind of cultivated sugar-cane being known to

perfect its seed. These cuttings are planted at intervals of 2 feet, in rows 3 feet apart, though this differs in different localities. Hand-holes are dug to set out the cuttings, though this method is being replaced, particularly in Louisiana, by the use of the plough. After the first cutting, new plants, known as "ratoons," grow up from the roots, and this method of growth is sometimes continued for 20 years before the vitality of the old roots is exhausted. When the canes are ready for harvest they are cut with hatchets as close to the root as possible, the juice from the lower joints being the richest. The tops are discarded. The canes are crushed in mills by heavy rolls, an average yield of 60 per cent. in juice being thus obtained. There is great loss in this method, however, and a new process, known as diffusion, is now becoming general. In this the pith is treated with successive applications of water, into which the juice diffuses, the yield being much greater and the juice purer, while the residuum of molasses, being free from plant-tissue, is of better quality.

Next in importance to the cane as a sugar-producer is the Beet-root. Up to the 18th century only cane-sugar was known in commerce, but in 1747 it was discovered that beets contained about 6 per cent. of sugar. During the Napoleonic wars, when the English blockade deprived France of sugar, Napoleon had experiments made on many plants, and, as beet-root proved the best, a beet-sugar factory was established at Lille in 1810. After the peace this industry, which had gained considerable development in France, declined, but improved processes brought it into vogue again, and at present beet-root sugar has largely driven cane-sugar out of Europe. The efforts to introduce the beet-root sugar industry into the United States have not met with much success. An attempt was made by Vaughan and Ronaldson, of Philadelphia, in 1830, but failed from ignorance of the proper process. At that time the European beet yielded only 4 to 5 per cent. of sugar, though the present yield is from 8 to as high as 14 per cent. In 1839 D. L. Child, of Northampton, Mass., made 1300 lbs. of beet-sugar. Nothing further of importance seems to have been done till 1863, when a large factory was established at Chatsworth, Ill. Other factories have since started in that region, but none of them have been very successful. In 1860 experiments in beet-root sugar-making began in California, and in 1870 the Alvarado Sugar Co. was formed. Other companies have since been established, with good promise of success. Yet they have met with difficulties from want of experience, while there are obstacles in making beet-sugar which do not exist in the case of cane. The product of sugar is but two-thirds that of cane, while the juice is highly charged with impurities which need removal by expensive processes. The total annual product of beet-root sugar in this country is estimated at 2000 tons, but there are indications of a steady increase. (See AGRICULTURE, Chap. V. 2. Beet.)

The chief native source of sugar in the United States is the Sugar- or Rock-maple, a tall and ornamental tree which flourishes widely throughout North America, though its abundance has been greatly reduced by the too free use of the axe. Its sap yields a profitable percentage of sugar, but the manufacture of sugar from it has as yet been mainly confined to farmers for home consumption. The season of maple-sugar making is very favorable for farmers, being in the early spring before the beginning of farm-work. At the first thawing of the ground, in middle or late February, the flow of sap begins, and the sugar-making continues through March and into early April, though the sap gradually diminishes in its saccharine qualities. The sugar-sap season is thus about six weeks long, the average product of sugar being one pound to 4½ or 5 gallons

of sap. In a good season an average tree will yield, during the best period of flow, as much as 3 gallons of sap daily, and produce about 4 pounds of sugar during the season. There are exceptional cases on record of 10 to 40 lbs. from a single tree. Trees, when fully mature, may be tapped many years without injury, there being cases of the same tree being tapped for 40 years without apparent harm.

The process employed in collecting the juice is to notch the tree $1\frac{1}{2}$ inch deep with an axe, or to bore auger-holes, the sap being caused to flow into collecting vessels. Three persons, it is said, can attend to 250 trees. The sap is evaporated in iron caldrons or shallow boilers, yielding a sugar of peculiar appearance and taste. The annual product of maple-sugar is estimated at 10,000 tons, but the data are not reliable. In Nebraska an equally good sugar is made from the ash-leaved maple; while some other American trees promise well as sugar producers. Vermont is the principal State engaged in the maple sugar industry. At the last census this State surpassed its nearest competitor, New York, by 2,200,000 lbs.

Maize or Indian corn was a source of sugar to the ancient Mexicans, and the maize-plants that bear no seeds are so sweet that the Mexican children are said to be as fond of them as of sugar-cane. It has been used to some slight extent for this purpose in Southern Europe and the United States, but a far more important sugar-yielding plant is the Sorghum, or Chinese Sugar-cane, which has been experimented upon with very promising results. The seeds of this plant were first brought to Europe in 1851, and to the United States in 1854. They were distributed among farmers, and found to flourish, in proper soil, from Maine to Texas. The culture rapidly spread, especially in the western States, mainly for the purpose of making molasses, though the leaves made excellent food for cattle. Until quite recently the sorghum-juice was almost wholly made into molasses. The census of 1870 reports only 24 hogsheads of sorghum-sugar, with 16,000,000 gallons of molasses. The census report of 1880 makes no mention of sorghum. The product had apparently fallen to unimportant dimensions. But since 1880 improvements in sorghum-sugar making have been introduced which promise to greatly revive that industry, it being possible to produce sugar of excellent quality from sorghum at a cost much below that of Louisiana cane-sugar. The powerful machines used to crush cane are not needed in the case of sorghum, which can be crushed much more easily. The area of possible sorghum-culture is extensive, being nearly the same as that of Indian corn, and while cane-sugar is profitable only on large plantations, sorghum can be raised profitably by ordinary farmers. The industry promises, therefore, to become an important one in the United States. (See AGRICULTURE, Chap. V. 4.)

Another source of American sugar is the Melon (*Cucumis melo*), which has assumed some little importance, particularly in California. Usually the juice is only evaporated to molasses, whose flavor is said to be much superior to that of beet-sugar. As a source of commercial sugar, melons cannot compete with cane or beet. Other sources of sugar are milk, which is used to some extent for this purpose in Switzerland, and the juice of several species of palm, particularly that of the wild date-palm, from which sugar is made in many tropical regions. The artificial conversion of starch into sugar was first effected by Kirchoff at St. Petersburg in 1702. The sugar thus produced is glucose, differing generally, as we have said, from sucrose. The making of it has become an extensive industry of late years in Europe and the United States. One further source of the sugar-product of this country is imported

molasses, which is largely used for the making of low grades of yellow sugar. The receipts of foreign and domestic molasses at the port of New York in 1880 was 14,849,760 gallons. Much of this, and of the molasses received at other ports, is worked over again for the sugar it contains.

An approximate estimate of the annual production of sugar in America outside the United States may be made from the replies to an inquiry addressed a few years ago by the Agricultural Department at Washington to the United States consuls at various American ports. These replies yield the following tabular statement of the American sugar-product:

Mexico, exports, 1885-86.....	6,389,208 lbs.
Lower California, annual product.....	2,400,000 "
Costa Rica, 1884 product.....	8,6300 "
Guatemala, 1886 product.....	21,672,740 "
Nicaragua, annual product.....	2,400,000 "
Salvador, annual product.....	18,000,000 "
Brazil, 1884-85 product.....	570,006,828 "
British Guiana, 1886 product.....	250,555,200 "
Dutch Guiana, 1886 product.....	15,355,751 "
Ecuador, annual product.....	11,000,000 "
Venezuela, annual product.....	15,500,000 "
P. e. u. annual product.....	89,000,000 "

The last-named country is excellently adapted to sugar-production, and in 1876 its crop was about 166,000,000 pounds, with promise of large increase through irrigation and the introduction of Chinese labor. But the war with Chili, the beet-root sugar competition, and other adverse influences have caused a considerable falling off in later years.

The West India product, as given in the same reports, is as follows:

Jamaica, average annual product.....	51,821,620 lbs.
Trinidad, 1886 export.....	118,523,940 "
Santa Cruz, 1885-86 product.....	17,925,232 "
Guadeloupe, 1886 product.....	88,297,307 "
Guadeloupe, 1887 estimate.....	132,300,000 "
Martinique, 1886 product.....	66,581,760 "
San Domingo, 1886 product.....	35,497,715 "
Porto Rico, estimated annual product.....	170,400,000 "
Cuba, total product for 1886 (estimated from another source).....	1,505,810,880 "
Barbadoes, 1884-85 (estimated from another source).....	135,968,000 "

Of the Cuban product, which is about one-third that of the whole world, 93.55 per cent. of the export comes to the United States. The product of cane-sugar in the United States is much less per acre than in the well-cultivated West India islands. In Barbadoes the yield per acre is about 5800 lbs.; in Louisiana, about 1350 lbs. The product of this country declined from 247,577 hogsheads in 1850 to 87,043 in 1870. This was in consequence of the war, during whose continuance the sugar-crop ran very low. It has been on the increase since 1870, and has again reached the amount of 1850. It is doubtful if it will increase considerably beyond this, and may, perhaps, ere many years, be surpassed by the sorghum-product. The following figures give the Louisiana production for several successive years.

1851.....	231,194,000 lbs.
1860.....	255,115,750 "
1875.....	10,800,000 "
1870.....	99,452,940 "
1880.....	198,962,273 "
1881.....	272,982,899 "
1882.....	159,874,350 "
1883.....	303,066,258 "
1884.....	287,712,230 "
1885.....	211,402,963 "
1886.....	286,026,496 "

The product of the other Gulf States, during the same period, has ranged from 5,000,000 to 16,000,000 lbs., the amount for 1886 being 16,128,000 lbs. During the same period the importations of foreign sugar into the United States have grown to so enormous dimensions as quite to dwarf the Louisiana product.

The figures for successive years are as follows :

1851	380,402,289 lbs.
1860	644,881,137 "
1870	1,196,753,549 "
1880	1,829,591,684 "
1881	1,946,745,215 "
1882	1,930,152,374 "
1883	2,137,607,765 "
1884	2,756,416,816 "
1885	2,717,881,053 "
1886	2,689,881,765 "

The sugar produced from other sources in the United States was, in 1883, as follows : Maple, 41,410,000 lbs. ; beet-root, 1,344,000 lbs. ; sorghum, 896,000 lbs. ; while the total consumption has grown from 917,109 tons, in 1880, to 1,389,125 tons, or 2,111,640,000 lbs., in 1886, the latter being a consumption of 53.3 lbs. per capita of population. In addition to the quantity consumed there were exported from the United States, in 1886, 175,836,220 lbs., almost entirely composed of sugar refined from imported sugars. The sugar refining process in the United States has of late years grown to enormous proportions, and forms one of our most important industries.

The total world's product of sugar was estimated some years ago at 3,500,000,000 lbs. (which has since more than doubled), of which 66.47 per cent. was cane, 27.87 beet, 4.29 palm, and 1.28 maple. Of this sugar the greatest consumers are peoples of the Gothic and Teutonic stock, the English and their offshoots being the highest. This group consumes 2,460,000 tons annually ; the Latin group not more than 465,000 tons ; and the Slavonic, 265,000 tons. The annual consumption of English-speaking peoples is about 1,850,000 tons. (C. M.)

SULLIVAN, SIR ARTHUR SKYMOUR, an English composer, was born in London, May 13, 1812. His father was professor at Kneller Hall, the training-school of the British military bands. The son was in boyhood chorister in the Chapel Royal, St. James's, and at the age of 14 competed successfully for the Mendelssohn scholarship. He studied under Bennett and Goss, and afterward at the Leipzig conservatory. He returned in 1861, bringing music for Shakespeare's *Tempest*. His next work was the cantata *Kenilworth*, for the Birmingham Festival of 1864. Then followed various overtures and oratorios, among which were *The Prodigal Son* (1868) and *The Light of the World* (1873). Meantime he had also commenced the series of operettas by which he is most widely known. The first of these was *Cox and Box* (1866) ; more successful were the *Trial by Jury* (1875) and *The Sorcerer* (1877). In these he was first associated with Mr. William S. Gilbert, who devised the dramatic parts, while Mr. Sullivan composed the music. The success of these operas was completely eclipsed by the authors' next joint labor, *H. M. S. Pinafore* (1878), which soon passed around the world with constantly increasing applause. *The Pirates of Penzance* (1879) was a remarkable second to the foregoing. Then came *Patience* (1881) and *Iolanthe* (1882), with great popularity assured by the authors' fame, but not increasing it. For his contributions to sacred music the University of Cambridge conferred upon Sullivan the degree of doctor in music in 1876, and Oxford gave the same degree in 1879. In 1883 the Queen conferred upon him the rank of knighthood. From 1876 to 1881 he was principal of the National Training School of Music. In his song-writing he has attained greater popularity than any other composer.

SULLIVAN, JOHN (1740-1795), a general of the Revolutionary war, was born in 1740 at Somersworth, N. H. Till called to take up arms he practised law successfully at Durham, N. H., and was elected a delegate to represent his State in the first Continental Congress at Philadelphia, in 1774. Returned to the

second Congress, he was appointed by it in June, 1775, a brigadier-general, and proceeded at once to the field. Here, proving himself brave, discreet, and skilful, he was quickly promoted to major-general. At the siege of Boston he was next in command to Gen. Lee, and in the battle of Long Island, when Gen. Greene was disabled, Sullivan succeeded to the command of his division. Acting, subsequently, under the immediate eye of Washington, he gained the great leader's confidence by his conduct in the battles of Trenton, Princeton, Brandywine, and Germantown. In 1778 he was assigned to the command of the forces in Rhode Island, and stood ready to act in concert with the French fleet under Comte d'Estaing in an attack upon the British at Newport, when the project was defeated by the retirement of the count on the appearance of the British fleet. After repulsing an attack of the enemy, Sullivan withdrew his troops with such skill and success as to earn the thanks of Congress.

In 1779 Congress was aroused by the massacres in Wyoming and Cherry Valley, perpetrated by the tribes of the Six Nations (Iroquois), and Washington determined to send a strong force under a resolute leader to take vengeance, and at the same time destroy a source of support for the enemy. Sullivan received the command, and, June 18, set out from Easton on his toilsome march. On Aug. 29 he came upon the Indians, with some British and Tories, under Joseph Brant (q. v.), entrenched at Newtown (Elmira). These he, after a struggle, dispersed, and thereafter set himself to the work of devastation. Forty villages were burned down, crops and orchards destroyed everywhere, and many savages slain. On Oct. 13 he returned to Easton, with only trifling loss. In 1779 Gen. Sullivan retired from the army and returned to his practice in Durham. Here he was the recipient of many honors from his native State, being chosen its delegate to Congress, its attorney-general, and three times its president. In 1789 he was appointed by Washington judge of the United States court of New Hampshire, which office he held till his death, in 1795.

SULLY, JAMES, an English psychologist, was born at Bridgewater, Somersetshire, in 1842. He was educated at the Independent College, Taunton, the Regent's Park College, London, and graduated at the University of London in 1866. He afterward studied at the University of Göttingen, and in 1871 entered on a literary career. He has contributed to the *Fortnightly* and *Westminster Reviews*, and is the author of several articles in the ninth edition of the *ENCYCLOPEDIA BRITANNICA*. Among his separate works are *Sensations and Intuitions* (1874) ; *Pessimism : a History and a Criticism* (1877) ; *An Introduction to Psychology* (1883).

SULLY, THOMAS (1783-1872), painter, was born at Horncastle, Lincolnshire, England, in June, 1783. His parents removed to the United States in 1792, and he began to paint at Charleston, S. C. In 1803 he went to Richmond, Va., then to New York, and afterward to Philadelphia, painting portraits in each of those cities. In 1837 he visited England to paint Queen Victoria in her coronation robes. This painting is owned by the St. George's Society of Philadelphia, and was lent by the society for the celebration of the Queen's Jubilee in 1887. Other noted portraits by Sully are those of Jefferson, now at West Point, of Lafayette, of Decatur, of Fanny Kemble Butler, of Dr. Benjamin Rush, and of George Frederic Cooke. His Washington Crossing the Delaware, now in Boston, has been popularized by engravings. Sully illustrated some books, but his fame rests on his portraits. He died in Philadelphia, Nov. 5, 1872.

His son, **ALFRED SULLY** (1821-1879), graduated at West Point in 1841, and served in the Florida and

Mexican wars. At the outbreak of the civil war he was still a captain, but was soon promoted major and colonel. During the Peninsular campaign he commanded a brigade, and he fought at Antietam, Fredricksburg, and Chancellorsville. In 1863 he was sent against the Indians in Dakota and was brevetted brigadier-general for his services there. In 1870 he was appointed colonel of the 19th Infantry. He died, April 27, 1879.

SULPHUR. This very important element is found widely distributed in earth and sea, in chemical combination in gypsum and pyrites, and dissolved in the ocean in the form of sulphates. It is also evolved from volcanoes and from vents in the earth in former volcanic regions, the principal American sulphur deposits being derived from sulphur vapor which has arisen from the interior in this manner and become condensed at the surface. Sulphur springs are numerous in the United States, and indicate a very general distribution of this element, either free or combined with hydrogen. In the eastern United States sulphur deposits occur on Cayuga Lake, and at Springport, Cayuga Co., N. Y.; on the Virginian side of the Potomac, about 25 miles above Washington; on Put-in-Bay Island, Ohio; in Kansas; at Tampa, Florida; and in Louisiana. These deposits are too small to have any industrial significance, except that of Louisiana. Here sulphur is found in Calcasieu parish, 13 miles from Lake Charles. The bed is a deep one, being reached only at a depth of 425 feet. It is said to average 100 feet in thickness and to be quite pure, and is underlaid by a bed of gypsum and sulphur. Some effort has been made to mine it, but with little success. An accident caused the works to be abandoned, and only recently have mining operations been renewed, with little result as yet.

Extensive and valuable beds of sulphur exist in some of the Pacific States, and here more vigorous efforts have been made to mine it, though the cheapness of Sicilian sulphur has caused the abandonment of many of the mines. Large deposits have been found in the Uintah Mountains of Wyoming, and also in southeastern Idaho, though these have not been utilized, from lack of railroad facilities. Sulphur also occurs in several localities in New Mexico and California. Some of the Californian deposits are large, but none, except that near Clear Lake, have been utilized, on account of the absence of cheap transportation. At Clear Lake the sulphur vapor issues from fissures in the rock, and is condensed near the surface. A peculiar feature of this deposit is the existence of a notable percentage of cinnabar in association with the sulphur. Borax also occurs in the vicinity. Sulphur was refined at this locality from 1865 to 1868, but the operations were then abandoned, on account of the fall in price of imported sulphur at San Francisco.

In Nevada sulphur is found in the craters of extinct hot springs in the Sage desert. There are many of these deposits, but of no commercial value. The sulphur beds in Humboldt county, Nevada, on the borders of the Black Rock desert, have been worked at the Rabbit Hole mines. The hills which here bound the desert have at their foot a strip of stratified volcanic tufa, which, at the locality of the mines, is richly charged with sulphur, all its interstices being filled with this element. The sulphur is of volcanic origin, and extends for several miles along the hills, in superficial deposits. The Humboldt Sulphur Company formerly produced 20 tons daily, but Sicilian competition has stopped the works.

A deposit of sulphur was found in 1885 in the mountains of Ventura county, Cal., but has as yet been used only for local purposes. In Utah the Mormons used sulphur purified from native ore for

some years. These deposits exist at Cove Creek, about 22 miles east of Black Rock, on the Utah Central Railroad. Here, as in the other places named, the sulphur has been deposited from vapor coming up from a great depth. This is still in progress, the prospecting holes becoming quickly lined with beautiful crystals of pure sulphur. In some localities the beds are 25 feet thick. In the four principal claims the mass of sulphur is estimated at 1,350,000 tons, much of it of high purity. The Cleveland mine, put in operation in 1885, yields ore of a remarkably high percentage of sulphur, it averaging at least 75 per cent., and frequently reaching 90 or over. Nowhere else do volcanic deposits of sulphur exist in such massive beds. This locality has, moreover, one advantage over the other American mines and those of Sicily in the presence of abundant fuel, the deficiency of fuel being a serious detriment to the Sicilian sulphur industry. All the sulphur produced in the United States at present is from the Cove Creek deposits, amounting to 3000 tons in 1887.

In addition to the American localities for sulphur above named, there are large deposits in Alaska, occurring near volcanic cones in the Aleutian and other islands. Sulphur mines exist in Japan, China, India, Turkey, Austria, Spain, Iceland, and the Samoa and Philippine Islands, but the principal supply comes from Sicily, though recently a considerable quantity of sulphur has been received in this country from Japan, and the importations from this source are increasing. The Sicilian sulphur, in addition to its abundance and cheapness of production, is free from arsenic, the most troublesome impurity, and is highly prized in the sulphuric acid manufacture. The annual product of the Sicilian mines increased from 143,323 tons, in 1862, to 376,316 in 1879, and is still increasing. The quantity of crude sulphur imported into the United States in 1886 was 117,538 tons, worth \$2,237,989, with over 3000 tons of refined sulphur, and flowers of sulphur in addition. Sulphur has declined rapidly in price of late years, falling from \$31 per ton of crude, in 1881, to \$19.50 in 1887. This is due principally to the rapidly increasing consumption of pyrites in the manufacture of sulphuric acid. Pyrites promises to yield an acid satisfactory for ordinary purposes more cheaply than ordinary sulphur, the impurities in this acid being too slight to detract from its value in refining petroleum and manufacturing fertilizers. Sulphur is being used in increasing quantities as "sheep dip," to prevent certain skin diseases in sheep. It is used in limited quantities in the gunpowder manufacture, in California to protect the vineyards from mildew, in the manufacture of ultramarine at Newark, N. J., and for some other purposes. Yet these consume but a small percentage, and nearly the whole product is consumed in the sulphuric acid manufacture. In 1884 about 306,000 short tons of this acid were made in the United States from crude sulphur, and 122,000 tons from pyrites. (C. M.)

SUMACH, the common name of plants of the genus *Rhus*, a wide-spread genus of shrubs or small trees of the order *Anacardiaceæ*, an order embracing the cashew, mango, and other tropical fruits. There are about 12 species of sumach within the United States, two of them marked by dangerously poisonous properties. They have compound leaves with alternate leaflets, and small polygamous flowers in terminal or axial panicles. In the sumachs proper the leaves are pinnate and the flowers in a crowded panicle; the fruit globular, and clothed with acid hairs. There is no plant more highly ornamental in autumn than the sumach, its long leaves then changing in color to a yellow, dark red, or brilliant scarlet, and forming one of the most beautiful ornaments of our autumn forests.

Of the American sumachs the largest species is *Rhus typhina*, the Staghorn or Virginia Sumach, which attains a height of from 10 to 25 feet, with a woody stem, and irregular or crooked branches. The young shoots are covered with a soft, velvety down like that on the new horns of the stag, which they resemble. The leaves are large and slightly downy beneath, changing in autumn to a purple or yellowish red. The flowers are greenish yellow in hue, in close spikes at the end of the branch, succeeded by drupes or berries densely clothed with crimson hairs. There are many varieties of this species, which is found wild almost throughout North America. On cutting the stem a yellowish resinous juice exudes. The wood and leaves are used for tanning the finer kinds of leather, while the roots are prescribed as a febrifugal medicine. The branches, when boiled with the berries, yield a black, ink-like tincture, and the berries may be employed in dyeing red. They are of a pleasantly acid taste, and may be eaten with impunity. They are said to contain malic acid in large proportion, and are used as a substitute for lemons in medicine, and in various domestic preparations.

R. glabra, the Smooth Sumach, closely resembles the above, and is the most common species. It reaches a height of from 2 to 12 feet. Like *R. typhina* it bears a dense cluster of greenish-yellow flowers, and of crimson fruit, velvety from its numerous hairs, and with pleasantly acid taste, its long compound leaves having from 11 to 31 leaflets. But its young branches are smooth instead of downy. A third species of the same group, *R. copallina*, the Dwarf or Mountain Sumach, is from 1 to 7 feet high, with downy branches, and its petioles wing-margined. It bears from 9 to 21 leaflets, whose dark-green hue and smooth, shining surface make this species a very handsome one. It frequents rocky hills, but may be found in lowlands. The three species above named, but particularly *R. glabra*, from its greater abundance, are of considerable commercial value, for their use in tanning light-colored leathers, in dyeing, and calico printing. The leaves are gathered somewhat extensively in Virginia and neighboring States for tanning purposes, they being dried, beaten, and ground to powder. They contain 12 to 20 per cent. of tannin. The Sicilian Sumach, *R. coriaria*, which is largely cultivated in Sicily for the same purpose, is much richer in tannin, containing from 30 to 35 per cent.

Another group of *Rhus* contains two very common and very poisonous plants, *R. toxicodendron* and *R. venenata*. Their flowers and fruit are borne in long and slender axillary panicles, and their leaves have fewer leaflets than the species described. *R. toxicodendron*, commonly known as Poison-ivy, is a widely extended plant. It has two forms, an erect and a climbing; the latter, which climbs by aid of rootlets over trees and fences, having been described as *R. radicans*. This species has three leaflets, and yields a milky juice which blackens on exposure and stains indelibly. It is dangerous from its wide distribution and its poisonous properties, which produce a highly disagreeable cutaneous eruption, attended with violent itching, in those who touch the plant. *R. venenata*, known as Poison or Swamp Sumach, Poison-elder, and Poison-dogwood, is a low tree of 10 to 20 feet high, with 5 or 6 pairs of leaflets, greenish-yellow flowers, and greenish-white fruit, which hangs in loose clusters from 6 to 8 inches long. It yields a milky juice which dries to a black varnish, resembling the Japanese lacquer. The leaves are smooth and shining, and the tree a very handsome one. In the autumn the leaves change to an intense red or purple. This species is found in swamps and moist, shady situations, from Canada to Louisiana. It fortunately does not affect

dry situations, like *R. toxicodendron*, as it is much more virulently poisonous than the latter, being dangerous to most persons who touch it, and to some who come near it. For an unknown reason some persons may handle it with impunity. Its effect is to produce small cutaneous pustules, filled with watery matter, and itching and burning severely, the effect lasting for a week or two, though yielding to certain remedies. The use of very hot water relieves the itching sensation, and it is said that carbonate of soda, bound on with a cloth and kept wet, is a sure and rapid cure for the eruption.

Of other American species may be named *R. aromatica*, the Sweet-scented Sumach, whose leaves when crushed yield an agreeable odor. In the western varieties of this species the odor is strong and heavy. Its leaves are among those smoked by the Indians in place of tobacco, under the name of Killi Kinick. *R. cotinus*, a Mediterranean species used for tanning, is the ornamental Smoke-tree of our gardens. In this species the leaves are simple. Of other important foreign species may be mentioned *R. succedanea*, from which Japan wax is obtained. This wax exists as a thick coating on the seeds, and is obtained by boiling. It is made into candles which resemble white wax and give a fine, clear light. *R. vernicifera*, a shrub much like *R. venenata* in appearance and in its poisonous properties, yields a milky juice which blackens on exposure, and forms the varnish used in the well-known Japanese lacquer ware. What are known as Chinese galls are yielded by another species, *R. semialata*. They result from the deposit of the eggs of an insect in the young shoots, and are largely imported into England for tanning and dyeing purposes. (c. m.)

SUMNER, EDWIN VOSE (1797-1863), general, was born in Boston, Mass., Jan. 30, 1797. He passed his youth at Milton, Mass., and received his education at the academy there. After a brief mercantile experience he was appointed, in March, 1819, 2d lieutenant of Second Infantry. He served with high credit in the Black Hawk and other border Indian wars, being promoted 1st lieutenant in 1823, and captain, Second Dragoons, March, 1833, in which capacity he commanded the school of cavalry practice, then at Carlisle, Pa. Commissioned major in 1846, he distinguished himself in the war with Mexico, leading the famous cavalry charge at Cerro Gordo, where he was wounded, and brevetted lieutenant-colonel. He gained fresh laurels at Contreras and Churubusco, and at Molino del Rey commanded the entire cavalry, holding in check 5000 Mexican lancers. For this exploit he was brevetted colonel. In 1851-53 he was governor of New Mexico, when he was selected to visit Europe to report on improvements in cavalry. In 1855 he was promoted colonel and led a successful expedition against the Cheyennes, whom he defeated at Solomon's Fork of the Kansas river. While in command of the Department of the West he rendered faithful service in the troubles in Kansas. In February, 1861, he had command of Pres.-elect Lincoln's escort from Springfield to Washington. In March he was promoted brigadier-general of regulars, and sent to supersede Albert S. Johnson, in command of the Pacific Department, but was recalled next year to lead the First Corps of the Army of the Potomac under McClellan. At Yorktown he was in command of the left wing, and from here to Malvern Hill, in spite of his advanced age, he distinguished himself in almost every engagement. At Fair Oaks his services were especially conspicuous, it being due to his soldierly promptitude in crossing the Chickahominy to the support of the attacked left wing that the battle was not a disaster. In the course of the Seven-days-fight he was twice wounded. For his services in the Peninsular campaign he was, in July, 1862, brevetted

major-general in the regular army. At Antietam he succeeded Hooker in command of the Union right, and gained the main successes in the fight, though again wounded. He commanded one of the three grand divisions of Burnside's army at Fredericksburg, and was assigned to make the disastrous attacks on Marye's Heights, Dec. 13, 1862. At his own request he was relieved in 1863, and was ordered to the Department of the Missouri. He was on his way thither when he died at Syracuse, N. Y., March 21, 1863. His son, bearing the same name, is a colonel in the regular army.

SUMNER, WILLIAM GRAHAM, economist, was born at Paterson, N. J., Oct. 30, 1840. After graduating at Yale, 1863, he went abroad, and pursued his studies at Göttingen and Oxford. He was an instructor at Yale from 1866 to 1869. Having taken orders in the Episcopal Church in 1867, he went to New York, 1869, as assistant minister to Dr. Washburn of Calvary Church, and editor of *The Living Church*. After a brief season of pastoral duty at Morristown, N. J., during which he translated Lange's *Commentary on the Second Book of Kings* (1872), he was called back to Yale in 1872 as professor of political and social science. In this post he has been active and successful, inaugurating a special library for the use of his classes, and supplementing the immediate duties of his chair by frequent publications and continual contributions to periodicals. With great earnestness and cogency he protests against what he considers economic heresies of the day, and argues for the ideas he has adopted—free-trade, a gold standard, and the *laissez-faire* principle. His *American Finance* (1874), with other papers, was contributed to the *Transactions of the Social Science Association*. His chief publications are: *History of American Currency* (1874); *Lectures on the History of Protection in the United States* (1875); *Andrew Jackson in the American Statesmen series* (1882); *What Social Classes Owe to Each Other* (1883); *Economic Problems* (1884); *Essays in Political and Social Science* (1885); and *Protectionism* (1885). Having made large plans of work for some years to come, he has mainly suspended his activities outside the college.

SUMTER, THOMAS (1734–1832), major-general in the Revolution, was born in Virginia in 1734. He volunteered against the French in 1755, and was present at Braddock's defeat. He afterward removed to the upper part of South Carolina, and there fought with the Cherokees. On the outbreak of the Revolutionary war he was made lieutenant-colonel of riflemen, and was engaged chiefly against the Tories. After the capture of Charleston by the British, in May, 1780, Col. Sumter took refuge at first on the swamps of the Santa, and later in North Carolina. In July he returned and routed a force in the Catawba, killing both the British and Tory commanders. He was then made brigadier-general and, on Aug. 6, won another victory at Hanging Rock, but on the 18th was routed by Col. Tarleton. However, he continued to harass the enemy until late in November, when he was severely wounded. In the following February he resumed his operations, and co-operated with Marion until the close of the war. He was a member of the State convention which ratified the U. S. Constitution, and was elected to the first Congress under it. He served as a representative eight years, and in 1801 was chosen U. S. senator. Retiring in 1810, he resided on his estate, near Camden, S. C., until his death, June 1, 1832.

SUNDAY. See SABBATH.

SUNFLOWER, a common American plant of the order *Compositæ*, genus *Helianthus*, of which there are about fifty species in North America. The genus includes annuals and herbivorous perennials, with rough stems and foliage, some species bearing tu-

bers. The common Sunflower, *Helianthus annuus*, has a flat floral receptacle of from 6 inches to a foot and more in diameter. It bears

Sunflower.

showy yellow, marginal ray flowers, while the disk is crowded with brownish tubular ones. The prevailing idea that the Sunflower is so called from its presenting its floral disk to the sun is an error. It derived its name from its resemblance to representations of the sun with a circle of rays. The perennial species have much smaller and often very ornamental flowers. Some varieties are double, the disk flowers developing in the same form as the ray.

H. multiflorus produces in late summer double flowers which present a close resemblance to the dahlia, and are very ornamental for garden purposes. California has a species with very large double flowers, one of the best adapted to garden cultivation.

H. annuus is now cultivated in most parts of the world, being raised in some parts of Southern Europe as a field crop. The numerous large seeds which are borne closely crowded on the disk are useful as food for cattle and poultry, and yield a large percentage of excellent oil, little inferior to olive-oil. An acre of good land will sometimes produce 50 bushels of seed, yielding 50 gallons of oil. The American Indians make bread of the seeds. The flowers abound in honey and are much visited by bees, while the leaves are useful as fodder, and the stems, which yield much potash, are used as fuel. In some parts of Europe a bouilli is made of the seeds as food for infants. Sunflowers are supposed to destroy malarial conditions and prevent miasmatic fevers, and they are planted in many places for this purpose. The pith is used sometimes instead of the true moxa. Sunflowers are not cultivated largely for commercial purposes in America, and seem injurious to the soil from their large absorption of potash. One of the tuberous species is the well-known Jerusalem Artichoke, called Jerusalem from a corruption of the Italian word *girasole*, and Artichoke from the resemblance in flavor of its tuber to the true artichoke.

SUPERIOR, LAKE, is the highest and most northern of the chain of Great Lakes, and the largest body of fresh water in the world. The shape is somewhat triangular, with the apex turned toward the west. The length is 380 miles; the average width, 80 miles. The circuit is 1500 miles, and the area is 32,000 square miles. The elevation above the level of the sea is 627 feet, and the elevation above Lake Huron, the next lower in the chain of lakes, is 49 feet. The elevation above Lake Huron is shown in St. Mary's river, the outlet of Superior, where a series of rapids formerly obstructed navigation. But of late a ship-canal about the falls of St. Mary has given access to Lake Superior for the largest craft upon the lower lakes.

The basin of the lake is not as interesting as the basin of Lake Ontario, either as to geological or topographical features (see ONTARIO). Lakes Huron and Michigan lie in the basin of the Devonian lakes, while Green Bay, an arm of Lake Michigan, belongs to the lower Silurian lakes. What are known as the Niagara rocks turn eastward from Green Bay to the head of Lake Erie, closing a geological and hydrological circle around the peninsula of Michigan. This forms the Devonian basin above noted: and in a third basin, excavated from the same swales, and thrown to the east by the great anticlinal which connects Detroit and Cincinnati, lie the waters of Lake

Erie. If this anticlinal did not exist Lake Erie would have had no existence, Lakes Huron and Michigan would have emptied their waters through Georgian Bay into Lake Ontario, and no falls would have been known at Niagara. The narrow belt of Niagara rocks curving about the head of Lake Michigan contracts the water-shed so that it is but a short distance to the tributaries of the Ohio, Mississippi, and other rivers that empty into the Gulf of Mexico. The basin of Lake Superior lies apart from the basins of the other Great Lakes at the extreme north-western limits of the formations which have been mentioned. Its basin is excavated, in part, from the lowest of the Silurian rocks. The mineral resources, chiefly copper, iron, and silver, for which it is celebrated, belong to still older formations surrounding it on all sides except the southern. The Laurentian and Huronian mountains support a country of forests and lakes of great extent, all the waters of which reach the shores of Superior. The region is really the western end of the great northern basin drained by the Ottawa, St. Maurice, and Saguenay rivers. It is, indeed, a wilderness of small lakes, the areas of which would make a water-surface as extensive as that of Lake Ontario; and the aggregate of rivers would greatly exceed the volume of the St. Lawrence river. Lake Superior, upon the American side, is somewhat low and sandy, the monotony of the shore being broken by the Pictured Rocks; but upon the Canadian side the banks are less uniform. Among the islands the Twelve Apostles, Isle Royale, and Grand Isle, belong to the United States; and the Silver, Montreal, Leech, Slate, St. Ignace, Pic, Sandy, Caribou, and smaller islands belong to Canada.

Lake Superior appears to have been comparatively free from the greater part of the fluctuations in the height of water that have been noticed upon the lower of the Great Lakes. On April 14, 1858, there was reported a change of 6 feet in the level of Lake Michigan. On May 10, 1823, according to De Witt Clinton, at Otter creek, on the Canada shore of Lake Erie, a wave came in 9 feet high, and the same occurrence took place at Kettle creek, 20 miles distant. Another, in 1830, reported 3 waves at Madison Rock, Lake Co., Ohio, the first rising 15 or 20 feet. In 1844, or 1845, a wave came into Euclid creek 15 feet in height, carrying everything before it. On Nov. 15, 1845, the water at Cleveland suddenly fell 2.8 feet during a high wind from the southwest. The U. S. government has, since 1859, taken 3 observations daily of the height of the water at the Milwaukee lighthouse. In May, 1887, the water in Milwaukee bay was a foot lower than in May, 1885. In September the water reached the highest level it had attained since 1859, a period of 27 years. In 1876, however, the water-level was very high, though not as high as in 1886. The lowest stage of the water recorded was in February, 1873, when the water-level was 4 feet below the level of 1833. The annual flood tide of the water is in September and October, and the annual ebb tide in January, February, and March. The greatest difference in the water-level noted in one year was in 1871, when it was 2.6 feet higher in the fall than in the previous winter. Before 1859 the observation of the water-stages depended upon private sources, and they are conflicting. In 1852 Solomon Juneau, who had resided in Milwaukee since 1818, said that never in his recollection had the water in the bay been so low as in 1820, and never so high as in June, 1838, when the old Indian race course was 6 feet under water. The difference between the water-stage of 1819 and that of 1838 was 4.8 feet at Milwaukee and 5 feet 3 inches at Detroit. This proves that Lake Michigan annually rises and falls from 12 to 18 inches. Lake Superior also shows fluctuations in a less degree. In 1789, opposite Isle

Royale, there was a sudden fall of four feet in the waters, and when they returned they did so with a rush, the vibrations continuing for several hours. In 1834 the waters above the Sault St. Mary rapids suddenly receded, and in half an hour returned with great velocity. In August, 1845, Dr. Foster states that while in an open boat between Copper harbor and Eagle river, an enormous surge, 20 feet in height and crested with foam, rolled toward the shore, succeeded by 2 or 3 swells. Dr. Foster observed repeated flows and reflux of the waters in 1847, 1848, and 1849, which preceded or followed storms on the lake. In 1851 D. D. Brockway reported, in a perfect calm, a sudden rise of 15 inches, and in another 2½ feet. The *Lake Superior News* of July 17, 1855, reported extreme fluctuations between 9 A. M. and 4 P. M. The U. S. government has recently finished several charts, based upon a long series of observations, which show that from 1882 to 1888 the surface of Lakes Michigan, Huron, and Erie was considerably above the mean level. The water at the present time is about one foot lower than the average from 1882 to 1887. The charts also show that the fluctuations in the lake levels have closely corresponded to the rainfalls. The fact may be considered established that the Lakes are simply great pools, forming part of the course of a river, and that they conform to all the laws governing the rise and fall of rivers.

As early as 1621 it was known that the shores of Lake Superior contained great mineral wealth. The French Jesuits first visited the great inland sea early in the beginning of the 17th century, but it was not till nearly fifty years later that René Mesnard visited the Lake and wrote an accurate account of the discoveries made on his voyage about its shores. Mesnard was followed by Allouez, Marquette, Dablon, and other French explorers, who made good maps of the lake, and gathered much information about the minerals from the natives with whom they came in contact. In 1721 De Charlevoix, an adventurous Frenchman, spent nearly a year on and about Lake Superior, and a few years later he published a graphic account of his discoveries in Paris. During the 18th century a number of explorers and trappers visited the shores of the Great Lakes, and while all of them seem to have formed a high opinion of the mineral wealth of the shores of Superior, the great distance from what was then the boundary of civilization made it impossible to operate mines of any kind. One English company, formed to mine copper, did send, in 1770-72, a few men to the north of Ontonagon river, but no copper was ever mined by them. In 1830 Dr. Douglas Houghton, an able geologist, visited the Lake Superior district in company with Gen. Lewis Cass, and continued his explorations for 10 years, spending nearly all of that time in northern Michigan. In 1841 he made a report to the State legislature setting forth his discoveries. The report made a sensation, and led to the development of the great copper interests of the district. In 1845 Dr. Houghton was drowned in L'Anse bay, and with him perished much valuable knowledge. In addition to discovering valuable veins of copper, it is certain that he found gold in nuggets and grains. His death was a great loss to the district. Since 1842 the development of the copper mining industry has been rapid and continuous (see COPPER).

In 1845 what the discoverers thought to be a solid mountain of iron ore was found at Negannee, Marquette Co., and the Jackson Iron Company was formed to mine and smelt the ore. From 1845 to 1855 very little was accomplished, but in the latter year the first canal at Sault St. Mary was completed by the State, and it became possible to ship ore to Eastern furnaces. In 1854 the old Cleveland mine

in Ishpeming sent a small cargo of ore to the Pennsylvania furnaces, and the Jackson mine had made several small shipments in previous years. In 1858 the Lake Superior, and in 1864 the Lake Angelina, mines were added to the list of producers; and since 1835 new mines have appeared each year on the list of shippers. In 1877 the first ore was shipped from the Menominee range, and in 1884 small shipments were made from the Gogebic and Vermilion iron range mines. Out of a grand total of 35,559,000 tons of iron ore shipped from the entire Lake Superior district since 1854 the Marquette county mines have furnished 25,149,603 tons; and of this amount four mines (the Cleveland, Jackson, Lake Superior, and Republic) have furnished over one-half. The Lake Superior is the largest iron mine in the world, with the Cleveland second.

The grain of the great Northwest has, of late years, sought an outlet to market through the harbor of Duluth (q. v.), the eastern terminus of the Northern Pacific Railway. The city, which now contains about 10,000 inhabitants, is upon a bay which has been artificially protected by 2 miles of breakwater. The early commerce of the Lake was conducted in small schooners whose capacity seldom exceeded 10 tons. The largest vessel in 1818 had a capacity of 133 tons. In 1852 the commerce of Lake Superior had increased to such importance as to necessitate the improvement of the St. Mary's river. The improvement included the digging of a canal, with locks, around the Sault St. Mary. The locks were sufficiently deep to pass vessels drawing 11 feet of water. In view of the possible increase of commerce on the upper Lake there was sufficient area between the gates of the locks to admit several vessels at once. It was supposed that this lock (opened in 1855) would accommodate the future traffic of Lake Superior, but in less than 10 years it could not accommodate the increasing traffic. Another lock was constructed, 515 feet long and 80 feet wide, and with 17 feet of water on its mitre-sills. It was opened for traffic in 1881. The maximum capacity was 96 vessels per day. The new lock of the canal, constructed on the site of the original canal, is 800 feet wide, and it has 21 feet of water on the mitre-sill.

The life of the lake traffic is the up-cargo, which uniformly consists of coal. This product is brought to Buffalo from the anthracite mines of Pennsylvania, and to Toledo and Cleveland from the bituminous mines of Ohio. This furnishing of coal for up-cargoes gives the Americans a great advantage over the Canadians; and the latter, after spending many millions to draw the trade of the upper Lakes to Montreal through the Welland and St. Lawrence canals, have failed to divert it because their products are chiefly imported goods not necessary to the life of miners and grain-growers. The enlarging of the St. Mary's canal has resulted in the building of a much larger class of vessels than it is possible to pass through the two Canadian canals.

A grain-boat, launched in 1887, draws, when empty, about 5 feet of water, and cost \$300,000. It is a three-decked steam-ship with a hull of steel, propelled by compound engines. The ship carries 2,800 tons of cargo and fuel on a draught of 15½ feet, and with this load will run 16 miles an hour. The length over all is 357 feet; depth, 25½ feet; beam, 41 feet. An iron or steel steamer of ordinary size, strong and seaworthy, and with great towing power, to carry 75,000 bushels of wheat and tow 3 consorts, costs about \$175,000. A wooden screw steamer, of the same carrying capacity and towing power, costs about \$125,000. A wooden schooner to carry 75,000 bushels of wheat, or 2150 tons, costs about \$75,000. A steel steamer and four consorts, as now built, represent about \$475,000. The five ships carry the wheat that grew on 22,000 acres of productive wheat land in

Dakota. This amount is sufficient to load 24 freight trains of 30 cars each, and each car carrying 500 bushels, and it would load nearly 50 canal-boats. Wheat can be carried by this method from Duluth to Buffalo, a distance of 880 miles, for 3 cents per bushel; and this rate is profitable if an up-cargo can be secured. The statistics for the close of the season of 1888 show that 6,500,000 tons of freight had been carried through the St. Mary's canal since the opening of navigation, a gain of 1,000,000 tons or more over any former year. Thus in six months (the season of navigation) as much freight was taken over this fresh-water route as passed through the Suez canal in twelve months. The average distance this vast quantity of ore, coal, wheat, flour, and other freights is carried by the vessels in which it passes through the canal at St. Mary's is estimated to be not less than 600 miles. This makes a total freight movement equivalent to the transportation of 3,900,000,000 tons one mile, for the whole season of navigation. In 1887 the entire freight business of all the railroads of New England was equal to the transportation one mile of 2,141,588,000 tons. The tonnage of all the railroads in the two Carolinas, Florida, Mississippi, Arkansas, Colorado, Oregon, and Georgia may be added before the total reaches the volume of traffic from Lake Superior through the St. Mary's river in six months.

(P. G. M.)

SUPPE, FRANZ VON, Austrian musician of Belgian descent, was born at Spalato, Dalmatia, April 18, 1820. He was educated at the University of Padua, studied music at Vienna, and became a conductor at Presburg, but afterward removed to Vienna. He has composed many masses, symphonies, and quartets. Of his overtures, *Dichter und Bauer* is the best known. He has also composed many operas, including *Das Mädchen vom Lande* (1847); *Franz Schubert* (1864); *Schöne Galatea* (1865); *Freija* (1866); *Isabella* (1869); *Fatinitza* (1876); *Boccaccio* (1879); *Donna Juanita* (1880). *Fatinitza* has been produced in England and America.

SURGERY, AMERICAN. The history of surgery in America begins during the latter See Vol. XXII. half of the last century. Before that p. 672 (p. 707 time there were capable practitioners, Am. Rep.).

men of great vigor and originality of thought, and large practical wisdom, but there were none who could be classed as surgeons, certainly no great surgeons. The medical men of one hundred years ago were those who first gave distinction, in the eyes of the civilized world, to the teaching and practice of surgery on this continent, and the history of surgery is really the history of their lives and achievements. Sydney Smith asked, in No. lxx. (January, 1820) of the *Edinburgh Review*, "What does the world yet owe to American physicians or surgeons?" Even at that date the question was one which could have been answered with pride by anyone familiar with the records of surgery in America, and at the present day the briefest enumeration of the valuable additions to surgical knowledge made by American surgeons would far exceed the limits of this article.

In the last half of the eighteenth century there flourished in America a number of distinguished men whose names are now familiar to surgeons throughout the world. Chief among these was Dr. Benjamin Rush, who, although he did not perform any great surgical operations, had acted as surgeon-general to one of the divisions of the Revolutionary army and had left in that capacity a most creditable record. In those days, as at the present time, medical men in America occupied the highest social rank. Dr. Rush, with others of his professional contemporaries, left his mark not only upon the surgery and medicine of that period but upon the general

literature, the politics, the philanthropy of the day. His influence was so wide-spread, his practice so extensive, and his skill in all departments of medical science so great, that his name naturally begins the list of great American practitioners; but his contemporary, Dr. John Jones, also a Philadelphian, was perhaps at the same period the best known surgeon of the country. He was a pupil and friend of Mr. Pott, a physician to the Pennsylvania Hospital, and vice-president of the College of Physicians. He wrote one of the first American treatises on surgery, which was published about 1777. He was an expert operator, particularly in cases of stone, which he extracted with great rapidity, a more important matter in those days than in these of anæsthetics. He is said to have performed the first operation of this kind in America in 1790. He attended Dr. Franklin, who suffered with stone in the bladder, and was the family physician of Washington.

Philip Syng Physick, the pupil of John Hunter and a professor of surgery in the University of Pennsylvania at the beginning of this century, earned the title of "The Father of American Surgery" by his admirable teachings and his skilful work as an operator. One of his most noted operations was that upon Chief Justice Marshall, from whom, when he was at an advanced age, he removed upward of one thousand vesical calculi. Dr. Physick originated a process of employing animal ligatures, selecting for the purpose dog-skin cut into suitable strips and then rolled on a marble slab to impart to them the requisite degree of hardness, roundness, and smoothness. Dr. John Syng Dorsey, after numerous experiments performed at the instance of Physick, was led to employ for this purpose French gut, using it in various amputations and in a number of capital operations, cutting the ends off close to the knot and treating the wound as if no ligature had been used. He was professor of anatomy in the University of Pennsylvania, and was the first surgeon in the United States who ligated the external iliac artery. Dr. William Gibson, who held the chair of surgery in the same institution, was the first surgeon who ever tied the common iliac artery. At about the same time lived Dr. John C. Warren, a son of Dr. John Warren, who was the surgeon-general during the Revolutionary war and professor of anatomy and surgery in Harvard College. He performed the first successful operation for the relief of dropsy of the pericardium, drawing off the accumulation of fluid with a trocar and cannula. The younger Dr. Warren succeeded his father in the joint professorship at Harvard, and was the first surgeon who ever gave ether as an anæsthetic during a surgical operation.

Dr. John Rhea Barton invented the well-known operation for the treatment of ankylosis, having performed excision of the hip on a sailor in 1826, described a fracture of the lower end of the radius still known by his name, introduced the bran dressing in the treatment of fractures and dislocations of the leg, and devised the bandage known by his name and employed in fractures of the lower jaw.

Dr. Valentine Mott, of New York, was the first surgeon who ever tied the innominate artery, but his reputation rests upon a long series of brilliant and successful operations. Dr. Gross says of him: "No surgeon, living or dead, ever tied so many vessels, or so successfully for the cure of aneurism, for the relief of injury, or the arrest of morbid growths." The catalogue, inclusive of the celebrated case of the innominate artery, comprises 8 examples of the subclavian artery, 51 of the primitive carotid, 2 external carotid, 1 common iliac, 6 external iliac, 2 internal iliac, 57 femoral, and 10 popliteal—in all, 138.

Dr. Ephraim McDowell, of Kentucky, was the first ovariectomist of the world, and shared with all other

great discoverers the universal opprobrium and bitter criticism of his fellows. He was also one of the most successful lithotomists of the early part of this century, attaining very enviable success in the lateral operation for stone.

The first ligation of the primitive carotid artery was performed in this country by Dr. Amos Twitchell, in 1807, some time before the famous case of Sir Astley Cooper, which was supposed to be the first of its kind on record.

In the treatment of ununited fracture, various improvements were made by American surgeons, notably the introduction of the seton by Dr. Physick, the union of the ends of the fragments by a metallic pin or screw as practised by Dr. Joseph Pancoast, and the freshening and wiring of the extremities as done by Dr. Rodgers, of New York. Dr. Reid, of Rochester, demonstrated by a series of dissections and experiments the possibility of reduction of dislocations by manipulation and by dispensing with the cumbersome and sometimes dangerous appliances which had been used for that purpose. His paper on this subject was followed by others by Prof. Gunn, of Chicago, and Moore, of Rochester; and, still later, by a comprehensive monograph by Prof. Bigelow, of Harvard.

The first operations for the relief of ankylosis of the inferior maxillary were performed by Dr. Carnochan, of New York, and by Dr. S. D. Gross, of Philadelphia.

Among the brilliant surgery of the century, we can only briefly record the operations of Dr. J. Kearney Rodgers, for ligation of the left subclavian between the scalene muscles; of Hunter McGuire for ligation of the abdominal aorta; of Onderdonk for ligation of the femoral in arthritis of the knee; for extirpation of the clavicle by Mott. The inventions or modifications of splints by Physick, Hodgden, N. R. Smith, and others were of the highest practical importance, while Fox's apparatus for fracture of the clavicle is yet in common and effective use. Dugas, of Georgia, pointed out one of the most valuable diagnostic signs of scapulo-humeral luxations, and Bigelow, in the paper above mentioned, revolutionized the theory of the mechanism of dislocation of the hip. Dr. Joseph K. Swift, of Easton, Pa., was the first surgeon to employ adhesive plaster as a means of extension in fractures of the lower extremities, an enormous step in advance, both as to comfort of patients and practical results obtained.

The employment of rest in general affections, which has recently been insisted on with great vigor by numerous European writers, was taught and practised in this country one hundred years ago by Dr. Physick. Trephining for bone abscess, usually credited to Sir Benjamin Brodie, was first performed by Nathan Smith, of New Haven, in the latter part of the 18th century. The first excision of the upper jaw ever performed was done by Dr. Jamison, of Baltimore, and the first resection of both bones by Dr. Rodgers, of New York. Dr. J. Mason Warren, of Boston, was the first to suggest the importance of dividing the muscles in the arches of the palate as a means of facilitating the union of the edges of the fissure after operations for cleft palate. Dr. Milton Antony in 1823 published, in the *Philadelphia Journal of the Medical and Physical Sciences*, a case in which he removed, along with a diseased rib, a large portion of lung-tissue which was involved. The drainage of the bladder through the perineum in case of chronic cystitis suggested by Mr. Guthrie, of London, was first put into practice by Prof. Willard, of New York.

The most important advance in the surgery of the urinary organs made within the century was introduced to the profession by Dr. Henry J. Bigelow of Boston, in January, 1878. Until that time it had been

the custom to greatly limit the period during which crushing operations were carried on, several sittings being necessary before the operation was completed, the maximum time of 8, 10, 15, or 20 minutes being allowed by various surgeons for the crushing of the stone. Dr. Bigelow showed that with proper care and gentleness the crushing could be completed at one sitting, even when it required several hours to effect this, and that at the same time the whole mass of debris could be evacuated instead of being left in the bladder to pass out with the urine. Dr. Bigelow greatly improved the lithotrite in several important particulars and invented an evacuating apparatus far superior to anything previously employed. His discovery was greatly facilitated by the observation of Dr. Fessenden Otis, of New York, who had previously shown that the calibre of the male urethra was far greater than had been supposed, and that catheters and bougies of much larger size than were formerly employed could be used with entire safety.

Extirpation of the coccyx for what was then known as coccygeal neuralgia was first done by Dr. J. C. Nott, of Mobile, although later Sir Joseph Simpson, not knowing of Nott's essay, described the same disease under the name of coccygodynia, and advocated the same method of treatment. J. Marion Sims in 1852 introduced to the medical world his operation for vesico-vaginal fistula, which has from that day to this maintained its position as an operative procedure and has perhaps done as much to restore to health and happiness large numbers of suffering women as any other operation in the entire domain of gynecology. The relief of chronic cystitis by permanent drainage of the bladder should also be accredited to the inventive genius of Sims, although at about the same time the same procedure was employed by Nathan Bozeman and Thomas Addis Emmett. Parvin's operation for the cure of urethro-vaginal fistula, the so-called Battey's operation, and the operation of gastro-elytrotomy, have all been either originally conceived or greatly improved by American surgeons. While considering the department of surgery known as gynecology, mention should of course be made of the forceps and the lever-pessary of Hodge, and the speculum, uterine repository, and probe of Sims.

In ophthalmic surgery should be mentioned the ingenious method of advancement of the lateral eye-muscles devised by Dr. A. E. Prince. This has received very wide adoption. A number of modifications of the various plastic operations upon the lids have appeared from time to time in the hands of American surgeons; notably Green, of St. Louis.

The method devised by the late Dr. C. R. Agnew, of New York, for removing a lens dislocated into the vitreous, with the aid of a bident, deserves mention; as do the able experimental researches of Knapp, of New York, and Weeks, of New York, in antiseptic eye-surgery; the discovery of the bacillus of acute conjunctival catarrh by Weeks, and his useful investigations of the bacteriology of xerosis conjunctivæ. The three best ophthalmoscopes which have emanated from American inventors since the introduction, years ago, of Dr. Loring's instruments, are those devised by Randall, Jackson, and Risley, of Philadelphia.

Medical teaching was even during the last century, in certain parts of the Eastern and Middle States, to be favorably compared with much of the instruction given at European schools. At the University of Pennsylvania, the centre of American medical education at this time, or connected with the Pennsylvania and Philadelphia hospitals, were to be found during the early years of this century many of the men whose names are still familiar to the profession throughout the world: John Syng Dorsey, Nathaniel Chapman, W. P. Dewees, Robert Hare, Samuel Jack-

son, Isaac Hays, Hugh Hodge, John Rhea Barton, Geo. B. Wood, William W. Gerhard, William Pepper, Sr., George W. Norris, and others whose teachings and writings have in no small degree aided in the progress of medical science. It would have been pleasant to point out in detail the work of each of these gentlemen; to dwell on the remarkable and diversified talents displayed by Dorsey, whose death at the age of thirty-five, just after his election to the chair of anatomy in the university, removed one of the most promising teachers ever seen in Philadelphia. He is said to have lectured on operative surgery, given practical instruction in *materia medica*, demonstrated anatomical details in the dissecting-room, and examined in physiology in the same day, with equal satisfaction to his pupils. We are indebted to Dr. Chapman, not only for innumerable *jeux d'esprit* and for brilliant medical teaching, but for the establishment in 1820 of the best medical periodical in America, if not in the world, *The American Journal of the Medical Sciences*, afterward so ably edited by the Drs. Hays, father and son. The first number bore on the title-page the quotation from Sydney Smith already alluded to. A special edition of this journal, with a single exception the oldest medical periodical in the English language, is now published in London for the benefit of British readers. To Dr. Gerhard belongs the honor of having been the first to point out clearly the distinction between typhus and typhoid fever, a differentiation which has saved thousands of lives. Much well-deserved praise could be written of the contributions of Barton to mechanical surgery and of his original operation for the cure of bony stiffening of the joints, the parent of all the orthopedic and subcutaneous surgery of the present day; of the advances made by Norris in conservative surgery; of the rare diagnostic acumen and brilliant clinical abilities as teacher and practitioner of the elder Pepper; of Wood's great labors in practical medicine and therapeutics, his undying record still existing in what is probably the most successful medical book ever published, *The United States Dispensatory*. John K. Mitchell's inquiries into the absorption of fluids and the origin of malaria were markedly in advance of their day, in some respects almost prophetic, while Hodge's invention of the lever-pessary, and Hare's of the oxy-hydrogen blow-pipe, cannot pass unnoticed. Dr. Gross, in his recently published autobiography, has given us a list of his contributions to medical science, a list of which any surgeon, or, indeed, any two or three surgeons, might be proud; but his researches on wounds of the intestines deserve special mention.

In 1824 the Jefferson Medical College, which was in its origin an offshoot of the University of Pennsylvania, was founded by Drs. McClellan, Eberle, Rhee, and Green, all graduates of the university, and in 1825 and 1826 the first course of lectures was given. A number of distinguished men have been connected with it from that day to this, notably Mutter, the founder of the Mutter Museum and lectureship at the College of Physicians; John K. Mitchell, the father of Dr. S. Weir Mitchell; Joseph Pancost, Charles D. Meigs, J. M. Da Costa, and Prof. S. D. Gross.

It seems hardly possible, and is perhaps hardly proper, in this article to enter with any detail into the history of more recent achievements by American surgeons. The earlier work of Dr. D. Hayes Agnew, in the improved operations upon vesico-vaginal fistula and of lacerated perineum, was most brilliant, and his teachings have had a lasting influence as regards those operations, while his work as a general surgeon has probably never been surpassed either as regards the ground covered, the results obtained, or the sound judgment displayed. The

work of Dr. S. Weir Mitchell, in reference to the results of injuries to nerves, constituted a new departure in the study of the pathology of these structures, and the results have been of vast importance to the practical surgeon. The work of the same physician in the investigation of the nature, results, and treatment of snake-bites also has been of the highest value. The statistical work of the younger Gross, the observations of Otis upon the capacity of the male urethra, which rendered possible the introduction of litholapaxy by Bigelow, the experiments of Senn, of Milwaukee, upon wounds of the intestines and intestinal sutures, the monumental labors of the compilers of the *Medical and Surgical History of the War of the Rebellion* and of Dr. Billings and his associates in the preparation of the *Index Catalogue* and *Index Medicus*, and the equally noteworthy work of many others who cannot be mentioned here, serve to illustrate the fact that American surgery to-day is as worthy of respect and admiration as at any period in the history of the country.

Perhaps the four great achievements of the century have been the introduction of anæsthesia; the establishment of ovariotomy as a justifiable procedure, the outcome of which has been modern abdominal surgery; the elevation of gynecology into a science; and the recognition of the principles of antiseptic surgery. When we remember that of these four the first three are clearly attributable to American genius and skill, and that nowhere in the world was the inestimable value of the fourth earlier appreciated than in this country, we can understand the debt which the civilized world owes to American surgery.

In the limits of this article the merest allusion to the most memorable occurrences has been possible, but much more of almost equal interest and importance may be found recorded in the *Essays of Professors Gross and Thomas* which may be found in *A Century of American Medicine*, published by Lea, of Philadelphia, in 1876. (J. W. W.)

SWAYNE, NOAH HAYNES (1804-1884), jurist, was born in Culpepper Co., Va., Dec. 27, 1804. While an apothecary's clerk at Alexandria he entered on a course of higher study, and was admitted to the bar at Warrenton, Va., in 1824. He then removed to Coshocton, O., and in a few years was elected to the State legislature. He was U. S. district attorney from 1830 to 1839, and in the meantime was elected judge of the county court, but declined. In 1836 he was again elected to the legislature, and there took a prominent part in organizing State asylums for the insane, blind, deaf, and dumb. His eminence in his profession induced Pres. Lincoln to appoint him a justice of the U. S. Supreme Court in January, 1862. He resigned this profession in 1881 on account of his advanced age, and died in New York City, June 8, 1884.

SWINBURNE, ALGERNON CHARLES, English poet and critic, was born at Pimlico, a suburb of London, April 5, 1837. He is the son—the eldest of six children—of Admiral Charles Henry Swinburne, R. N., and of his wife, Lady Jane Henrietta, daughter of the third Earl of Ashburnham; and the grandson of Sir John Edward Swinburne, Bart., of Capheaton, Northumberland. From the blood and influence of the latter, a man of no common mould, who lived and retained his natural force unabated to the extreme age of ninety-eight, the poet has evidently derived much that is characteristic in him. As a boy, young Swinburne's tastes ran on the one hand to poetry, and on the other to swimming and riding. In these physical exercises he is said to have excelled. He was not merely a great reader of poetry, but of poetry of a very high order of excellence. In one of his books he speaks of "having, from well-nigh the first years I can remember, made of the

study of Shakespeare the chief intellectual business, and found in it the chief spiritual delight of my whole life." Poets and authors of the first rank exerted a most powerful influence on the impressionable mind of the lad when he was, to use his words, "most susceptible of influence, and least conscious of it, and most in want." As a child, he often found an all-sufficient delight in the mere music of verse the meaning of which was quite beyond his power of comprehension. His memory for poetry was specially retentive. His favorite authors so impressed themselves on his mind, apparently with little or no direct effort on his part, that he early had by heart long passages from them—even entire poems. As was most natural in a lad so constituted, efforts at original composition of poetry soon followed, and some of these boyish effusions he afterward published in his somewhat notorious collection of *Poems and Ballads*.

Young Swinburne was sent to Eton, and after five years there entered Balliol College, Oxford, as a commoner, in 1857. While at the university he was one of the chief among some half-dozen student contributors to a short-lived college magazine, *Undergraduate Papers*. His contributions included, among other things, what was considered a very clever parody. After something less than four years at Oxford, he left the university without taking a degree. He was, however, a natural scholar, and his attainments, especially in literature and the languages, have been considered—and justly—as truly phenomenal.

Without ever having personally met Walter Savage Landor, at that time England's oldest living poet, young Swinburne came to entertain for him the most enthusiastic admiration and regard, and in 1864 he made a veritable hero-worshipper's pilgrimage to Italy, for no other purpose than to make the personal acquaintance of his hero. The aged poet received him cordially, and the two spent some months together at Florence, during the last year of Landor's life.

After previous publications, not without merit, Mr. Swinburne first achieved name and fame by the publication, in 1865, at the age of twenty-eight, of his classical drama, *Atalanta in Calydon*. *Atalanta* is a tragedy upon the severest Greek model—certainly a unique, and by many considered an almost faultless, work of art. It was the result of a happy inspiration, born of prolonged training in the classical languages. Nor is it a mere Greek imitation; it is rather the product of a Greek imagination. Hence *Atalanta* ranks with the very best productions of its kind. Seldom or never has it been given to an author to achieve popularity by the publication of a work which naturally appeals to so restricted an audience. Yet it would not be wide of the truth to say that Mr. Swinburne did achieve just that—over and above the reputation he gained within the world of letters. Few modern resuscitators of the ancient classical drama have more nearly contrived to "make the dry bones live."

But while *Atalanta* made the young author famous, *Poems and Ballads*—published the following year—in this country under the title of *Laus Veneris*—came very near making him, in certain eyes at least, infamous. The book was violently assailed as being grossly sensual and immoral. Parts of the collection were declared to be indecent, others blasphemous. In defence of the work the plea has been urged that the poems were, as Mr. Browning says of a volume of his own, "though lyric in expression, always dramatic in principle, and so many utterances of so many imaginary beings." But many who accepted the plea refused to consider all parts of the work as artistic in the best sense. Still others, who entertained a high opinion of the young

author, both as an artist and as a man, admitted that in the selection of some of his subjects he had been injudicious and unfortunate. The outcry against book and author was so sudden, sharp, and emphatic, that his publishers, the Messrs. Moxon & Co., withdrew the book almost immediately from circulation. It was reissued with little delay, however, by another publisher, at whose instance, and in whose behalf, Mr. Swinburne published a brief reply to his assailants, *Notes on Poems and Reviews*, in the course of which he says: "The book is dramatic, many-sided, multifarious, and no utterance contained therein can properly be assumed as the assertion of the author's personal feeling or faith. . . . If literature indeed is not to deal with the full life of man and the whole nature of things, let it be cast aside with the rods and rattles of children. Whether it affects to teach or to amuse, it is equally trivial and contemptible to us; only less so than the charge of immorality. Against how few really great names has not this small and dirt-incrusted pebble been thrown. . . . I knew that belief in the body was the secret of sculpture, and that a past age of ascetics could no more attempt or attain it than the present age of hypocrites."

Mr. Swinburne was not content to be known and criticised as a poet. He turned critic himself, and discussed all sorts of literary and artistic subjects in the current reviews. His prose work materially enhanced his reputation in certain quarters, while much of it also has been sharply criticised and even ridiculed.

Although the immediate descendant of two very old and exclusive families of the English aristocracy—himself barely without the pale of the titled aristocracy, and only through the operation of the English laws of primogeniture—Mr. Swinburne early espoused the most radical opinions politically, and sought by his pen to promote the cause of republicanism in Europe. In *A Song of Italy* he apostrophizes—almost to apotheosis—Garibaldi and Mazzini. His republican ardor and hopes for the future found still further expression in the *Ode on the Proclamation of the French Republic*, the *Songs before Sunrise*, and the *Note of an English Republican on the Muscovite Crusade*.

In 1871 Robert Buchanan, the poet, published in one of the reviews, under the assumed name of "Thomas Maitland," an article, "The Fleshly School of Poetry." This was aimed more especially at Mr. Dante Gabriel Rossetti, but in the acrimonious discussion which ensued Mr. Swinburne—a warm personal friend of Rossetti's and classed with the latter, by Mr. Buchanan, in the obnoxious "Fleshly School"—became involved, and published a reply (to Mr. Buchanan) entitled *Under the Microscope*. In the course of this paper he also gave expression to some of his opinions respecting American poets and poetry. Poe and Whitman were singled out as deserving of high commendation, but most of their fellow-craftsmen in America were characterized as "mocking birds," or, where really independent of models, as "corn-crakes"—because of the harshness and worthlessness of their song.

Erechtheus is a second classical drama. It is generally regarded as inferior to *Atalanta*. The *Note on Charlotte Brontë* is a brochure full of enthusiastic and exalted praise of Miss Brontë, in which the gifted author of *Jane Eyre* and her sister Emily are rated with Mrs. Browning, and far above George Eliot, George Sand, and other women in the world of letters. *A Year's Letters by Mrs. Horace Mann* is Mr. Swinburne's first and thus far his only effort in the field of prose fiction.

Mr. Swinburne has shown a most remarkable power of imitating the characteristic style of other poets of various ages and countries. *The Heptalogia*

was an anonymous imitation of Tennyson, Browning, and others; himself included, the better to divert suspicion from him as the author. But though the authorship in this case did not remain undiscovered, some work of this sort by Mr. Swinburne has deceived the very elect among the critics. *Chastelard*; *Bothwell*; and *Mary Stuart* form, together, a dramatic trilogy on the Scotch Queen, whom Swinburne condemns for reasons peculiarly his own. *Marino Faliero* is certainly superior to Lord Byron's tragedy of the same name.

Swinburne's rightful place among the poets is the subject of wide—almost violent dispute. While some regard him as an unintelligible "language-slinger"—an insatiable word-monger—others, conceding his poetic genius, deplore the sensuous tone of his muse. A poet of acknowledged power has said that in all his many volumes "he has written no line that lingers in the memory, has uttered nothing that resembles a thought;" which has been indorsed by a reviewer in the sentence: "A severer criticism could not be conceived and a truer one its author never uttered." On the other hand, judges are not wanting who rate Swinburne not merely among the poets of high rank, but who assign him a high position in that select coterie. Among his defects may be mentioned, first, a fatal facility for the selection of unfortunate if not positively inartistic themes—themes that to a vast majority of cultured people are physically or morally repulsive, if not both: second, an inability to exercise true artistic restraint—extravagance in the treatment of his subjects—overdoing, generally, in what he says and in his way of saying it: third, a readiness to subordinate, if not actually to sacrifice, sense to sound, to rate formal execution of greater import than insight, the outcome of which tendency is to render his poetry often mere word-music devoid of sufficient thought to vitalize it: fourth, a proneness to be vague, indefinite, unintelligible—nay more, to be at times positively inane. Beyond this, severer critics assert that he is a man so wrapped in a self-limited world that he is constitutionally incapable of broad human sympathies. This want of community of feeling with his fellows is shown by the slight tendency of his poetry to find lodgement in the minds and memories of men. "By necessity, proclivity, delight, men quote," and from none more freely than from the great writers of all time—whether Biblical, classical, or modern—yet mankind are not given to quoting Swinburne. However learnedly some men argue about him, however prone some are to praise him, they are slow to quote him. Prolific as his pen has been, it has added next to nothing to the deathless and divine in literature which graves itself at once and indelibly on human hearts and memories. And in proportion as this point is well made, it would seem to argue some vital defect in him as a man, and consequently as an artist, which must ever exclude him from the circle of the world's great poets.

As for his merits, his champions aver that all his work, prose as well as poetry, evinces a knowledge, vast and varied, of the world's best lore; an eager and passionate love of beauty; an enthusiastic devotion to art for its own sake; an impetuous, luxurious, and wholly distinctive individuality of style; a quickness to perceive and a readiness to praise everything in the work of his fellows that seems to him meritorious; a lofty artistic *hauteur*—an implicit belief in himself which, however egotistic it appear to the vulgar crowd, has always been, still remains, and must ever continue a prime requisite of Genius.

They call attention, in his verse, to his facile alliterations, to his pleasant surprises in metre and rhythm, to the originality and scope of his melodious variations; to his curiously intricate stanzaic forms, all singularly felicitous in their ever-recur-

ring assonances and concordant sounds. Nor will they admit that his poetry is merely exquisite sound. They find it as full as adverse critics find it void, of suggestive and valuable thought. They dote on his "marvellous execution," his "wonderful technique," but assert that these powers are but superadded to that of vitalizing his verse with a substance of thought worthy of the lyric splendor shown in its construction. To them his strains are as subtly strong as they are surpassingly sweet. He is a sovereign among rhythmists—in all moods an absolute autocrat of verse.

Whatever may be our conclusions about Swinburne, it is certainly long since any man in the literary world has provoked discussion more varied, more extended, more unintermitting. For wellnigh a quarter of a century he has been a most prominent figure among contemporary men of letters. Writing not for gain, but simply and solely to please himself, following unfalteringly his own star, whithersoever it might take him, refusing to yield so much as a single article in his artistic code, to gain a friend or to placate a foe, he has produced a mass of work which, good or bad, is undeniably original and characteristic, and from which neither his brother artists, nor the camp-following critics, nor the hosts of the philistines have been able successfully to avert their gaze. He is a man whom his admirers are unable to sufficiently praise, and whom his detractors treat with all manner of contempt, save the supreme contempt of silence and neglect.

Swinburne's collected works comprise: *The Queen Mother and Rosamond* (two plays, 1890); *Atlantia in Calydon: a Tragedy* (1895); *Chastelard: a Tragedy* (1895); *Poems and Ballads* (1896); *Notes on Poems and Reviews* (1896); *A Song of Italy* (1897); *William Blake: a Critical Essay* (1898); *Siena: a Poem* (1898); *Ode on the Proclamation of the French Republic* (Sept. 4, 1870); *Songs before Sunrise* (1871); *Under the Microscope* (1872); *Bothwell: a Tragedy* (1874); *George Chapman: a Critical Essay* (1875); *Essays and Studies* (1875); *Songs of Two Nations* (1875); *Erechtheus: a Tragedy* (1876); *Note of an English Republican on the Muscovite Crusade* (1876); *A Note on Charlotte Brontë* (1877); *A Year's Letters by Mrs. Horace Mann* (1877); *Poems and Ballads: Second Series* (1878); *A Study of Shakespeare* (1879); *Songs of the Spring Tides* (1880); *Studies in Song* (1880); *The Heptalogia; or, The Seven against Seme: a Cap with Seven Bells* (1880); *Mary Stuart: a Tragedy* (1881); *Dignat: a Dramatic Monologue* (1881), which was a parody of one of Tennyson's poems; *Tristram of Lyonesse: with Other Poems* (1882); *A Century of Roundels* (1883); *A Midsummer Holiday, and other Poems* (1884); *Murino Kaliero: a Tragedy* (1885); *A Study of Victor Hugo* (1886); *Miscellanies* (1887); *Loirine: a Tragedy* (1887); *Select Poems* (1887). In his *Miscellanies* have been included several of his characteristic contributions to the *ENCYCLOPEDIA BRITANNICA*. (C. E. W.)

SWINE were probably imported from Spain by Columbus into Hispaniola (Hayti) in 1493, and into Florida by De Soto about 1538. Within a century later breeding stock found its way into Nova Scotia, Newfoundland, Canada, and Virginia.

Notwithstanding the receipt from foreign countries of an occasional pair or trio of superior specimens, such as the Woburns or Bedfords sent by the duke of Bedford to Gen. Washington, there was, prior to 1815-30, but little interest manifested in any general improvement, and the stock of the country was mainly made up of coarse, ungainly brutes, considered of moderate value to roam at will in the forests, where, subsisting on mast, roots, and reptiles, they grew in from two to four years to weights of 150 to 400 pounds gross, of fairly good and sweet-tasted meat, with a minimum quantity of fat or lard. Since 1830 many improved swine of different names and characteristics have been imported from England for breeding purposes, and used with remarkable effect in giving to America a greater number of superior pork-producing animals than is possessed by any other country. The old-time stock of England was coarse and deficient in fattening

qualities; and the great means of improvement was the using of boars of the compact, fine-boned Chinese, Siamese, and Neapolitan stock, to which all the best swine now on the globe are largely indebted for their most valuable characteristics.

The swine of America consist mainly of the following breeds or their crosses: Berkshire, Poland-China, Chester, white Suffolk, Essex, Jersey reds, Cheshires, and Victorias. The breed known as Poland-China had its origin early in the present century in southwestern Ohio. John Wallace, of Union Village, while visiting Philadelphia in 1816, purchased an imported boar and three sows, designated as "big Chinas," and took them to Warren county. Their progeny became popularly known as "Warren county hogs." They were improved by mixture with Berkshires in 1836 and with "Irish Graziers" in 1838. The stock thus produced constitute the basis of the breed known as "Poland-China." There appears to have been no admixture of other blood in the breed since 1840. For a long time there was great diversity in the designation for the breed, but the National Convention of Swine-breeders, at Indianapolis, in November, 1872, compromised on Poland-China as the name by which it should be called.

Great improvement has been made, especially since 1870, in the form and finish of these swine, and while prior to that time they were white- and black-spotted, they are now bred more nearly black, and in many instances are marked very much like the Berkshire. The best specimens are well-haired, have good length, short legs, broad, straight backs, deep sides, flanked well down on the leg, broad, square hams and shoulders, deep chests, short, full, high-crested necks, heavy joints, short heads, fine muzzles, moderately fine and drooping ears, and have very quiet, gentle dispositions. For size they are equal to any swine raised, and are properly classed among the largest breeds. Much attention is being paid to keeping accurate record of their pedigrees, and for that purpose different associations of breeders have published herd-books. Among these are the *American*, at Vinton, Iowa; the *Central*, at Indianapolis, Ind.; and the *Ohio*, at Dayton, Ohio.

The Berkshire was well known as a distinct breed in Southern England a century ago, when the stock of that name were ungainly, coarse-boned—but short-legged—flat-sided, and lop eared, and required two to three years in maturing. On account of yielding a large percentage of lean meat mixed with their fat, they were favorites for making bacon.

The earliest importation of these into the United States is supposed to have been made to New Jersey in 1823; the next to the neighborhood of Albany, N. Y., in 1832. In 1839, Bagg and Wait, English farmers, settled in Orange Co., N. Y., began importing largely, selling their stock in Kentucky, Tennessee, Missouri, and the South. They were at that time animals of superior excellence, but under the neglectful system of stock-raising then prevailing they deteriorated rapidly and their popularity waned. English farmers, however, never lost faith in the value of the breed, and continued to improve it from year to year. About the year 1865 enterprising Americans were again attracted by the good qualities of the swine and began making importations of the best obtainable. Each year since has witnessed improvement in form and quality, and the stock has been distributed throughout every State and Territory, being greatly esteemed either for pork-production pure or for crossing on other sorts.

Among the qualities that commend the Berkshires to the favor of breeders and feeders are their remarkable uniformity in color, form, and quality; great muscular power, vitality, and activity; strong diges-

tive and assimilative powers; their aptitude for fattening and attaining heavy weights. Their flesh is the highest quality of pork for all purposes. Their standard of characteristics and markings, as agreed upon by American breeders in 1872, was as follows: "Color black, with white on feet, face, tip of tail, and an occasional splash of white on the arm. While a small spot of white on some other part of the body does not argue an impurity of blood, yet it is to be discouraged, to the end that uniformity of color may be attained by breeders. White upon one ear, or a bronze or copper spot on some part of the body, argues no impurity, but rather a reappearing of original colors. Markings of white other than those named above are suspicious, and a pig so marked should be rejected. Face short, fine, and well-dished, broad between the eyes. Ears generally almost erect, but sometimes inclining forward with advancing age; small, thin, soft, and showing veins. Jowl full. Neck short and thick. Shoulder short from neck to middling deep from back down. Back broad and straight, or a very little arched. Ribs long and well sprung, giving rotundity of body; short ribs of good length, giving breadth and levelness of loin. Hips good length from point of hips to rump. Hams thick, round and

England. Jeffries' stock and its progeny continued to be bred on and with the original stock of the county, until its hogs attained a wide reputation for both size and quality. In Pennsylvania and neighboring States the new breed was the favorite. At the fair of the U. S. Agricultural Society at Philadelphia in 1856, at the U. S. Fair at Richmond, Va., in 1858, at the State fairs of Maryland, Virginia, and Pennsylvania, they stood almost unrivalled. After 1865 much attention was given in all parts of the Union to raising better stock than had before been common, and the reputation acquired previously by the Chester county swine caused them to be eagerly sought in greater numbers than could be supplied, but a reaction followed.

Though not adapted to all localities, the Chester whites are in many respects swine of superior value. In some portions of the West and Southwest they are considered more liable to skin diseases than black hogs. The Chester whites are among the most docile of swine, and properly classed as belonging to the large breeds; individuals of it have been fed to the enormous weight of 1300 pounds. The standard of characteristics adopted for the breed by the Swine-breeders' Convention in 1872

Chester White Hogs.

deep, holding their thickness well back and down to the hocks. Tail fine and small, set on high up. Legs short and fine, but straight and very strong, with hoofs erect, legs set wide apart. Size medium, length medium; extremes are to be avoided. Bone fine and compact. Offal very light. Hair fine and soft; no bristles. Skin pliable." Since the preparation of this standard great advances have been made in developing still heavier hams, deeper sides, broader, straighter backs, and shorter heads.

American breeders of Berkshires were first to adopt a systematic plan for the registration of swine pedigrees, and in 1875 organized, at Springfield, Ill., the American Berkshire Association for the purpose of the "collection, preservation, and dissemination of reliable information on the origin, breeding, and management of Berkshire swine, and the publication of a herd-book or record of Berkshire pedigrees." Several volumes have already been issued, and the record is considered of great value to breeders.

The Chester white takes its name from Chester Co., Pa., where James Jeffries, in 1818, brought a pair of superior white pigs from Bedfordshire,

was as follows: "Head short, and broad between the eyes; ears thin, and projecting forward; neck short and thick; jowl large; body lengthy and deep, and broad on the back; hams full and deep; legs short and well set under for bearing weight; hair thin, white, straight, without bristles, and if a little wavy not objectionable; tail small." Since the adoption of this standard the tendency has steadily been toward reducing somewhat the coarseness of their bones, shortening their heads, and breeding them with smaller, finer ears. The improvement has been so great that the best specimens of the breed are nearly models in form. Large, pendulous ears, coarse heads, long, coarse tails and hair, and coarse, spongy bones, are not, as in times past, characteristics of the breed, and the enormous weights to which they were formerly fed are not now considered most desirable or profitable. For farmers who desire white hogs somewhat smaller and quicker-maturing the Chester sows are excellent for crossing with smaller boars, such as the Suffolk breed affords; those who make a specialty of the latter breed claim that such a cross makes "the best Chester white possible." In Pennsylvania they

have always been held in the highest esteem. In form, size, and general characteristics, except color, they are very similar to the Poland-Chinas, but for some cause have not retained their popularity of former years among the pork-raisers of the corn-growing States, where the dark-haired hogs now largely predominate. Very little attention seems to have been paid to keeping records of the breeding of different families or strains of Chester whites.

The Suffolk is a small white breed, originated in England, where pigs essentially the same are also called Yorkshires, or small Yorkshires. English authority says they have been continually intermixed with mutual advantage, and pigs of exactly the same form, the result of crosses, are exhibited under the name of Yorkshires or Cumberlands; also, that the improved Suffolk, the Middlesex, the Colehill, and the Prince Alberts (or Windsors) of England were all founded on the Yorkshire-Cumberland stock. Though known to some extent in all the States since 1855, they have never attained any general popularity as farmers' hogs, largely due to the fact that they were too small, not wholly satisfactory as breeders and nurses, had skins too delicate to withstand the exposure they encountered, and too nearly resembled some of their remote ancestors, described as being "perfect bladders filled with hog's lard, and nearly of the same size and quality."

The standard characteristics of the Suffolks are: "Head small, very short; cheeks prominent and full; face dished; snout small and very short; jaw fine; ears short, small, thin, upright, soft, and silky; neck very short and thick, the head appearing almost as if set on front of shoulders; no arching of crest; chest wide and deep—elbows standing out; brisket wide, but not deep; shoulders thick, rather upright, rounding outward from top to elbow; crops wide and full. Sides and flanks—long ribs well arched out from back, good length between. Shoulders and hams—flank well filled out, and coming well down at ham; back broad, level, and straight from crest to tail; no falling off or down at tail; hams wide and full all the way down; legs small and very short, standing wide apart—in sows just keeping belly from the ground; bone fine; feet small, hoofs rather spreading; tail small, long and tapering; skin thin, of a pinkish shade, free from color; hair fine and silky, not too thick; color of hair pale yellowish white, perfectly free from any spots or other color; size small to medium."

The Essex is a long-established breed of English origin, but, though of admitted good qualities, it has never become widely disseminated or popular in the United States. It was improved by the introduction of some Neapolitan hogs into England by Lord Western. The reputation of the Essex breed was established in England in 1840.

They are classed with the small breeds, but are about the largest of that class, and frequently grow to weights that would entitle them to consideration among the larger breeds, often weighing 400 to 600 pounds at maturity, though usually most profitably slaughtered young for fresh pork, breakfast bacon, or family use, for which they are highly esteemed, their meat being well-flavored and fine-grained, and their lard firm and white. When properly dressed they are but little darker than other hogs, even those with white hair. The standard agreed upon for them by the National Convention is as follows: "Color black; face short and dishing; ears small, soft, and stand erect while young, but coming down somewhat with advanced age; carcass long, broad, straight, and deep; hams heavy and well let down; bone fine; carcass, when fat, composed mostly of lard; hair ordinarily rather thin;

fattening qualities very superior. As breeders, prolific and fair nurses."

The swine variously known by the names of "Jersey reds," "red Berkshires," "Durocs," or "Saratoga reds," are quite common throughout the United States. They are of a reddish, sandy, or bronze color, and of widely varying characteristics. For over sixty years sandy-colored hogs have been numerous in southern New Jersey, especially in Salem and Burlington counties, and highly esteemed; there is a tradition that they are descendants of early importations from England of the unimproved Berkshires. The National Swine-breeders' Convention in 1872 agreed that their positive origin was unknown, but reported the following as characteristics of good "Jersey reds": "They should be red in color, with a snout of moderate length, large lop ears, and small head in proportion to size and length of body; should be long in the body, standing high and rangy on thin legs; bone coarse; heavy tail and brush; hair coarse, including the bristles on the back."

Swine called Cheshires were mentioned by English writers subsequent to 1840-45 as "long-legged, long-eared, unprofitable giants, all but extinct." Between 1860 and 1870, in Jefferson Co., N. Y., the favorite swine were of a large white sort known as the Jefferson county or Cheshire breed, or sometimes "improved Cheshire." During those years they were exhibited at the fairs of the New York State Agricultural Society, and latterly received nearly all the prizes awarded on large breeds. The accepted description of them is that they are pure white, with very thin skin of pink color, and little hair, though not wholly uniform in the latter respect, as pigs in the same litter differ widely in the quantity of hair; the snout is often long, but very slender and fine; the jowls are plump, and the ears erect, fine, and thin; shoulders wide and hams full; their flesh is fine-grained, and they yield an extra quantity of mess pork in proportion to offal.

An American breed known as Victorias had its origin in Saratoga Co., N. Y., about 1855. They were a combination of the "Grazier," "Byfield," "Yorkshire or Suffolk," and another hog, white, long in body and well-haired, and the best of them are descendants of a sow named (about 1860 or 1862) Victoria. They have a good coat of fine, soft, white hair, and fine heads closely set on their shoulders; snout short and face slightly dished; ears erect, small, and thin; shoulders round and full; legs short and fine; back broad, straight, and level, and the body long; hams round and swelling, and high at base of tail, with plaits or folds between the thighs; tail fine; rosettes common on the back; skin thin, soft, and elastic; the flesh fine-grained and firm, with thick side pork. They can be made fit for slaughter at almost any age.

The pig being omnivorous, its highest and most rapid development calls for a generous variety of feed. During the period of growth there should be a smaller percentage of carbonate or fat-formers supplied, and the percentage of phosphates and nitrogenous compounds increased. Indian corn is rich in fat; oats, on the other hand, are especially rich in bone- and muscle-formers. Clover and grass so combine the two that when young hogs are grazed on these they make a good growth of bone and muscle, and a development of stomach which enables them to assimilate a greater amount of corn at fattening-time.

As a scale of 100 points for judging swine the National Convention of Breeders agreed upon the following: Back, 10; long ribs, 8; short ribs, 7; shoulder, 8; ham, 12; length of body, 6; flank, 6; twist, 6; snout, 4; jaw, 3; face, 3; ear, 2; neck, 4; belly, 4; skin, 5; hair, 3; bone, 3; legs, 3; feet, 2; tail, 1. (F. B. C.)

SYBEL, HEINRICH VON, German historian, was born at Düsseldorf, Dec. 2, 1817. He was a pupil of Ranke, at Berlin, though he was chiefly educated at the University of Bonn, where he became professor extraordinary in 1844. In 1841 he had published a *History of the First Crusade*, exposing some popular errors in regard to that movement. After publishing his essay on the *Origin of the German Kingdoms* he was called, in 1845, to Marburg as professor of history. In 1847 he began his political career as representative of the university in the Hessian parliament and was sent to the Congress of Erfurth. Duke Maximilian II. of Bavaria called him in 1856 to Munich, where he founded the first historical seminary in Germany, and published an historical review. In 1861 Von Sybel returned to Bonn as professor and was soon sent as deputy to the Prussian chamber. In 1867 he was elected to the constituent diet of the North German Confederation, and took an active part in Bismarck's struggle with the Ultramontane party. In 1874 he was elected to the Reichstag, and in the next year was made director of the State archives at Berlin. His edition of these important historical documents, commenced in 1878, is expected to comprise 70 volumes. Von Sybel's great work is *Geschichte der Revolutionen seit von 1789 bis 1795* (5 vols., 1853-67), which has passed through several editions and has been translated into English. It was based upon a faithful study of the archives in Berlin, Vienna, London, and The Hague. Von Sybel has also published *Die Erhebung Europas gegen Napoleon* (1860), and numerous historical essays.

SYLVESTER, JAMES JOSEPH, English mathematician, was born in London, Sept. 3, 1814. His early education was at private schools in that city and at the Royal Institution, Liverpool. His later training was at St. John's College, Cambridge; but, being a Jew, he could not receive a degree, though in 1837 he was second wrangler, and in 1839 was elected a Fellow of the Royal Society. In 1872, however, the degrees then denied him were finally bestowed; he is also M. A. of Dublin and Oxford, LL. D. of Dublin and Edinburgh, and D. C. L. of Oxford. He studied law at the Inner Temple and was called to the bar in 1850. He was made professor of natural philosophy at University College, London, and in 1852 was called to the chair of mathematics in the University of Virginia. Returning to England in 1862, he became professor in the Royal Military Academy at Woolwich, which post he held for five years. On the organization of the Johns Hopkins University at Baltimore, in 1877, Sylvester was made professor of mathematics there, but at the end of 1883 he was elected Savilian professor of geometry at Oxford, which chair he has since held. Although he has published no separate work of importance, his contributions to mathematical periodicals have been of the highest merit. His papers number altogether 250, and relate to every department of mathematics, but especially to higher algebra, which he greatly enlarged by his theory of reciprocants. He is also the inventor of the plagiograph and other geometrical instruments. Some sonnets and other poems from his pen attest the versatility of his genius. He was the first editor of the *American Journal of Mathematics* (founded in 1878), and second president of the London Mathematical Society.

SYNAGOGUE. The word *keneseth*, the proper Hebrew word for synagogue, is probably post-biblical, and certainly does not occur in the Old Testament. The word used in Ps. lxxiv. 8 is not *keneseth*, but *moedh*, the word commonly employed to denote the great festivals: The Passover, the Pentecost, the Feast of Tabernacles. The Septuagint

and Vulgate translations give the word its usual meaning in this passage (*rās iōyrās*; *omnes dies festos Dei*); and the meaning is entirely consistent with the context. The burning of the sanctuary was virtually the burning of all the solemnities that had centred there. But even if the word *moedh* be here taken in the unusual meaning of "appointed places," or "places of assembly," there is nothing to establish an identity between these and the fully developed synagogue, or to justify the assertion that "such synagogues existed in all parts of Judæa in the time of Ps. lxxiv. 8, or to prove that this psalm was written after synagogues became a recognized institution.

The Great Synagogue.—The statement that Jewish tradition assigns to the so-called Great Synagogue "supreme religious authority from the cessation of prophecy to the time of the high priest Simeon the Just" needs modification. The traditions (see Maimonides in Ugolino, vol. i., col. 12; also *Hieros. in Megil.*, fol. 70, col. 4, cited in Lightfoot, Pitman's ed., x. 525, and elsewhere) include among the men of the Great Synagogue Daniel and his three companions, with Haggai, Zechariah, Ezra, Nehemiah, and Malachi, and speak of other prophets, in considerable numbers, as also included. It is necessary to distinguish between what the traditions say of the Great Synagogue as an organization and what they say of the men of the Great Synagogue as persons. Much of what is said in regard to the organization is apocryphal enough, especially with the interpretation put upon it by some modern writers; but no men whose names appear in history are more real than those just mentioned and their associates. Whatever Kuenen or others may have shown as to the organization sometimes described as the Great Synagogue, or as to the original meaning of the name, neither he nor anyone else doubts that most of those who are called the men of the Great Synagogue were veritable men, who actually did literary work in connection with the Old Testament; and it is certain that the traditions concerning this work, however distorted or exaggerated some of them may be, have a basis of truth, and that parts of the truth can be disentangled from the fiction. In particular, the most important Old Testament questions connected with the men of the Great Synagogue are questions that have nothing to do with the organization, but only with the men.

This succession of men maintained itself for several generations after the succession of the prophets had ceased, and in this sense the men of the Great Synagogue are later than the prophets; but it should not be forgotten that they were also for several generations contemporary with the later prophets, and included these prophets among their number.

The statement that only modern writers since Elias Levita attribute to the men of the Great Synagogue the completing of the Old Testament canon is perhaps true, if applied strictly to the alleged organization of that name; but it breaks down if applied to the men of the Great Synagogue as distinguished from the organization. The traditions attribute to Ezra, Nehemiah, and other men of the Great Synagogue a vast amount of work on the Old Testament books, including the "writing" (that is, in many cases, the editing) of all the latest of them. In the sense, therefore, that the canon was actually complete the moment the latest writings included in it were finished, the traditions attribute to the men of the Great Synagogue the completing of the canon; it may perhaps be true that these traditions, when rigidly sifted, recognize no other "fixing" of the canon than this, but this is the determination of it that is all-important. See, e.g., *Baba Batra* (Ven. ed. of 1520), fol. 14a. (W. J. B.)

T.

TABERNACLE: *The Central Sanctuary of Israel, and its Religious Feasts.* The author

See Vol. XXIII of the article TABERNACLE, in the ENCYCLOPÆDIA BRITANNICA, says in regard to the detailed accounts of the

Israelitish Tabernacle and its worship, as these are given in the Priest-code, that "the whole description is ideal," that it "throws back into the time of Moses the whole scheme of worship and ritual of which the second temple was the centre." This position is an essential part of the view of the Old Testament held by the succession of writers on Biblical subjects in the ENCYCLOPÆDIA BRITANNICA; if it be admitted that the tabernacle and its services, as described in the Pentateuch, are matters of historical fact, then their whole scheme falls to the ground.

The Biblical accounts testify that the tabernacle was constructed in the vicinity of Mount Sinai. This gives the author of the article on SINAI, in the BRITANNICA, an opportunity to open and close his treatment by an attack on "the historicity of the Hebrew records involved." He says: "The absence of exact topographical detail on the part of the Biblical narrators, who always speak of Sinai as if it were a single summit, and give no hint about several summits of which it is one, shows that in their time there was no real tradition on the matter, and that all attempts at identification are necessarily vain." But this writer cannot be unfamiliar with the fact that the usual Hebrew word for mountain denotes a given mountainous region as properly as a single summit. Which of the two it denotes in any particular passage, can only be known from the context, or from known facts concerning the topography. He has no right, therefore, to say that these narrators always speak of Sinai as if it were a single summit; neither he nor anyone else knows that to be a fact; the presumption is that they speak interchangeably, sometimes of the region and sometimes of a particular peak, and there is no evidence to overthrow this presumption. The fact that their lack of definition in this particular, and their lack of details, render it difficult to settle some points as to the topography, is not at all discrediting to the historicity of the writings. It is a matter of fact that in the Sinaitic peninsula, as well as in Egypt and in Palestine, a growing knowledge of the topography, while it often overthrows our theories as to the meaning of the Biblical statements, yet shows the correctness of the statements themselves. Even a man who holds that the Pentateuchal accounts of the tabernacle were written after the exile, ought to be able to see that they were written by some one who was familiar with the Sinaitic peninsula.

The Pentateuchal accounts inform us that Israel had a public sanctuary-tent, earlier than the one that Moses made at Sinai, Ex. xxxiii. 7-11. See also, in this work, ISRAEL, *Period I, Institutions*. It is not a fair reading of the history to regard this as an older and contradictory mention of the tabernacle that Moses is said to have made at Sinai. On the contrary, it is spoken of as a part of a group of pre-Sinaitic institutions, that were either superseded by the legislation at Sinai, or incorporated into it.

The Priest-code writings circumstantially describe the tabernacle itself and its furniture, its system of offerings and sacrifices, its priesthood, its sacred year of daily burnt offerings, sabbaths, and appointed festivals, and in virtue of all these, its character as the one legal sanctuary of Israel. In regard to each of these points, the books of the Old Testa-

ment, with more or less continuity, give the subsequent history of the institutions founded by Moses, and in regard to each of them, the several writers in the ENCYCLOPÆDIA BRITANNICA deny the historicity of the account thus given.

The tabernacle itself and its furniture. Besides what we might infer from what is said concerning the sacrifices, the priests, the festivals, etc., we have the following direct statements: The tabernacle (*mishkan*) was recognized as in existence, in western Israel, after the conquest by Joshua, Josh. xxii. 19, 29. The tent of meeting had been set up at Shiloh by the congregation of Israel, Josh. xviii. 1. The inheritances of the tribes were distributed before Jehovah, at the doorway of the tent of meeting in Shiloh, Josh. xix. 51. In Eli's time, the tent of meeting was still in Shiloh, perhaps within the temple inclosure there, 1 Sam. ii. 22. When David brought up the ark to Jerusalem, he pitched a tent for it, 2 Sam. vi. 17; 1 Chron. xvi. 1, while the Chronicler adds that the *mishkan* of Jehovah was then at Gibeon, close by, and the force of Levitical ministers was divided between the two points, xvi. 39. This statement is repeated in 1 Chron. xxi. 28 sq., 2 Chron. i. 3, and on the face of it seems to be confirmed by what is said as to Solomon's sacrificing in Gibeon, and his vision there, 1 Ki. iii. 4-5; ix. 2. During all this period, Jehovah represents himself as dwelling in tent and *mishkan*, 2 Sam. vii. 6. The *mishkan* of Jehovah's glory is recognized in Ps. xxvi. 8. The tent of Jehovah, with its altar (the tent at Gibeon, rather than the one at Jerusalem), figures prominently in connection with the accession of Solomon, 1 Ki. ii. 28, 29, 30; i. 39. And finally, we are told that, at the dedication of Solomon's temple, the priests and Levites brought up not only the ark, but "the tent of meeting and all the holy utensils that were in the tent," 1 Ki. viii. 4; 2 Chron. v. 5. In Eli's time we are told that the ark was in the temple at Shiloh, 1 Sam. iii. 3, presumptively in its proper sanctuary in the tabernacle, which we have seen was also there; and that it was removed from Shiloh at the time when it fell into the hands of the Philistines, iv. 3, 4. Thus separated from the tabernacle, we have a pretty full account of its various fortunes, till the two were placed in Solomon's temple. The shew bread of Ex. xxv. 30; xxxv. 13, appears in 1 Sam. xxi. 6, and again among the arrangements of Solomon's temple, and those in preparation for the temple, 1 Ki. vii. 48; 2 Chron. iv. 19; 1 Chron. xxiii. 29, etc. In 2 Chron. i. 5, cf., 1 Chron. xxi. 29, it is said that the brazen altar made by Bezaleel was still in use in Solomon's time.

Certainly this line of statements, especially when corroborated by the many parallel allusions to the sacrifices, the festivals, the priesthood, and other institutions that had their centre in the tabernacle, appears, on the face of it, to be entirely credible as history. If we are not to accept the statements, we ought to have satisfactory reasons for rejecting them. Of what sort are the reasons for this, as they are actually adduced?

The author of the article on the Tabernacle, in the BRITANNICA, says: "The Chronicler indeed, who had before him the Pentateuch in its present shape, assumes that after the Israelites entered Canaan the tabernacle continued to be the one legitimate place of sacrifice, until it was superseded by Solomon's temple, and represents it as standing at Gibeon in the days of David and his son (1 Chron. xxi. 29; sq. 2 Chron. i. 3). But the book of Kings knows Gibe-

on only as 'the greatest high place' (1 Ki. iii. 4). But we have seen that the continued existence of the tabernacle is not a mere assumption of the author of Chronicles, but a matter of fact attested by the books of Joshua, Samuel, and Kings. The fact that the book of Kings knows of Gibeon as the seat of the great high place (this book recognizes no other high place as legitimate) is perfectly consistent with the view taken in Chronicles, that the great high place was constituted as such by the fact of the presence of the tabernacle there. The account in Kings does not contradict that in Chronicles, but confirms it.

On this point, the author of the same article says: "Two passages in the . . . books of Judges, Samuel, and Kings speak of the tabernacle . . . ; but external and internal evidence show them to be interpolated (1 Sam. ii. 22; 1 Ki. viii. 4)." But the mention of the tabernacle in 1 Ki. viii. 4 is in the Septuagint, as well as in the Hebrew copies, and that in 1 Sam. ii. 22 is in the Hebrew and the Alexandrian Septuagint, though not in the Vatican copy of the Greek. In each case the mention of the tabernacle fits the context, and fits all the Biblical statements that touch the matter. A man who regards the Priest-code writings as unhistorical must needs find in that circumstance a reason for regarding these passages, which ascribe historicity to the Priest-code writings, as interpolations; but really there is no other reason for so regarding them.

The author of the same article further insists upon what he regards as the fact that at Shiloh the ark "was housed not in a tent but in a temple (1 Sam. iii. 3, 15)." But, admitting that there was a permanent temple structure at Shiloh, the account testifies that the tabernacle was also there, and there is no difficulty in understanding that the tabernacle may have stood somewhere within the temple precincts, with the ark in its holy of holies, and the legal arrangements for sacrifices connected with it.

The offerings and sacrifices connected with the tabernacle. The Pentateuchal writings testify that Israel had institutions of this sort from the time when Abraham first came to Palestine; that there were Israelitish institutions of sacrifices in Egypt, just before the exodus, and in the wilderness, in the interval between the exodus and the giving of the Sinaitic legislation, Gen. xii. 7; xiii. 2 *sq.* et al.; Ex. x. 25; xii. 3-24; xviii. 12; xxiv. 5, etc. They affirm that, under Moses, these earlier institutions were regulated by various statutes, and supplemented. The collection of them found in the Pentateuch is in no proper sense a code, but is simply a succession of papers placed one after another, with no apparent system. The ritual described differs materially from that of either Solomon's temple, or the second temple; it provides for no courses in the ordering of the priests and Levites, no corps of gate-keepers and other attendants of that class, no singers, no wood-offering (*cf.* Neh. x. 35 [34]; xiii. 31), no money provision for current expenses (*cf.* Neh. x. 33-34 [32-33]), the half shekel tax of Ex. xxx. 12-16; xxxviii. 25-26, being a very different thing from the permanent tax of Nehemiah. On the other hand, traces of the existence of many of the sacrificial usages described in this legislation are found throughout the history, from Joshua to Nehemiah. The great day of atonement, indeed, is not mentioned in the Old Testament outside the Pentateuch. The word for sin-offering, except perhaps in Ps. xl. 7 [6], occurs only in Ezekiel, the Pentateuch, and the post-exilic books, and is first applied in Chronicles to the times of Hezekiah. The current phrases to describe atonement for sin occur in Deuteronomy, in 1 Sam. iii. 14, in 2 Sam. xxi. 3, and in Ps. li. 9 [7] and other Psalms, but they are abundant only in the Priest-code and the later Old Testament books.

But most of the other distinctive terms for sacrifice are found sprinkled through the books of Judges, Samuel, Kings, and the earlier prophets.

The passages in which these terms occur are very numerous. It is impossible here to refer to them in detail. A thorough examination of them would not lead to the conclusion that the Pentateuchal system of sacrifices and offerings was in complete operation in Israel throughout the period from Moses to Nehemiah; but equally, it would not justify the conclusion that the essential points of the system were ever unknown in Israel during that period. Such passages as Deut. xii. 8 and Josh. v. 2-8, show that the system, so far as the whole people was concerned, was in very imperfect operation even in the time of Moses himself. The ritual of the times of Eli has its points of difference from that of the Pentateuch, as well as its points of resemblance. But in the successive revivals of ritual, under David and Solomon, under Hezekiah, under Josiah, under Ezra, the claim made in the records is that the revival followed the Mosaic precepts that were in the possession of the priests; and there is nothing in the phenomena of the times to contradict this claim.

In the article *TITHES*, in the *ENCYCLOPEDIA BRITANNICA*, the view is presented that the older Israelitish legislation had nothing to say of tithes, but demanded as due to Jehovah the firstlings of the flock and herd, and also, without fixing the amount, the first-fruits of agricultural products; that before the writing of the Deuteronomic legislation in the seventh century B. C., the amount of the first-fruits had come to be fixed at a tenth; that in that code, Deut. xii. 6, 11; xiv. 22 *sq.*, an innovation is introduced to the effect that the tithes "must be consumed at a central, instead of a local, sanctuary;" and that in the times of Ezra and Nehemiah there was put in force "the new law of the priestly code (Num. xviii. 21 *sq.*), in which it is formally laid down that the tithe is a tribute paid to the Levites, who in turn pay a tithe of it to the priests." It is sufficient disproof of this that the Priest-code, Deuteronomy, and Nehemiah alike regard the tithes as something entirely distinct from the first-fruits, Num. xviii. 12, 13, 21-26; Deut. xvi. 10, 12; Neh. x. 35-38; xiii. 44. This theory of the evolution of the tithing system has no elements of continuity or of probability that would justify a truly critical scholar in accepting it in preference to the specific testimony of the different accounts, which ascribe the laws concerning tithes to Moses.

In the article on *SACRIFICE* in the *ENCYCLOPEDIA BRITANNICA* is a similar theory of the evolution of sacrificial worship. It holds that a sacrifice "is primarily a meal offered to the deity." Either the deity alone partook, as in the case of the burnt offering, or he shared the sacrificial feast with his worshippers. Animals came to be preferred as sacrifices, because animal food was thought of as more luxurious than vegetable food. In certain stages of savagery, it is unlawful for a tribesman to eat the totem animal of his own tribe, and praiseworthy for him to eat that of a hostile tribe, and thus certain animals come to be regarded as fit for food or sacrifice, while certain others are unfit. "Generally speaking, then, the original principle on which a sacrificial meal is chosen is that men may not eat what cannot be offered to their god." As the flesh of their enemies is particularly choice food, in the view of certain savage tribes, the practice of offering human sacrifices began, being, in many cases at least, the product of cannibalism. But somehow or other, a different idea came to be connected with human sacrifices—that of the slaying of the victim to placate the deity, who was offended, and whose vengeance must be satisfied; the sacrifice became pious, and in due time there came to be pious ani-

mal sacrifices also. In some cases, the offering of an animal was of the nature of a fine; "more usually, however, the life of an animal is accepted by the god in place of a human life."

This theory is supposed to find some support in the Old Testament. It is asserted that "the slaughter of an animal . . . seems to have been always sacrificial in early Greece," and then, that "among the Semites sacrifice and slaughter for food are still more clearly identified; the Hebrews use the same word for both." This last statement has only a meagre support from the Hebrew lexicons, and really none at all from the usage of the Old Testament; there is no instance where a word of the stem Z-B-H occurs where it may not naturally be understood to denote a sacrificial feast, either as a fact, or, in a very few instances, figuratively, while the words of the stem T-B-H are not currently used to denote sacrifice. Again, the alleged connection between totemism and the distinction of clean and unclean animals cannot be traced in the Pentateuchal scheme; the animals allowed for food are different from those allowed for sacrifice, the food animals including many species that are named, and an immense number of others that fall under general designations; while those for sacrifice are three species of animals and two of birds. Further, the theory just described requires us to regard "the presentation of the gift" as "the central feature in every ordinary act of worship." If the laying of the hand on the head of the victim, in the Hebrew ritual, was a mere act of presentation, then this fact fits the theory; but if it was rather an emblematic confession of ill desert, and a prayer for pardon (Lev. xvi. 21; v. 5; Num. v. 7), it does not at all fit the theory.

On the basis of this theory it is sometimes argued, that, in such cases as that of Jephthah, we have a picture of the religion of Jehovah in the stage when it still recognized the propriety of human sacrifices; that the story of Abraham and Isaac indicates a later stage, in which this religion outgrew the idea of human sacrifice; that its sacrificial system gradually developed until, in post-exilic times, the full pentateuchal ritual had come to be in existence. In regard to all ideas of this kind, it is sufficient to say that they contradict the only known ancient records that bear testimony in the case, and that they have no such intrinsic credibility as to justify our accepting them in preference to the records.

Concerning the *priesthood of the tabernacle*, and the questions depending on it, see PRATER, in this work.

The *sacred Year of the Tabernacle*. In Numbers xxviii., xxix., and elsewhere in the Pentateuch, we find precepts for a class of acts of worship at certain fixed times throughout the year—the morning and evening daily offerings, the special offerings and services for the Sabbaths, the new moons, the Passover, the Pentecost, the Feast of Tabernacles, with its preliminary ceremonials of the blowing of trumpets and the day of Atonement. Both the Pentateuch and the other historical books that mention these attribute the institution of them to Moses, with the modification that some of the elements involved were incorporated into the Mosaic legislation from older sources.

In opposition to the statements of the records, the author of the article on the SABBATH in the *ENCYCLOPEDIA BRITANNICA* cites the words of Jesus in the New Testament to prove that the Sabbath of the Tanaite scribes (which he assumes to be the same with that of the Priest-code) was different from that which prevailed in Israel before the exile. He makes a grave mistake when he assumes that the Pentateuchal Sabbath is that of the scribes, and is to be interpreted by their spirit, instead of by the spirit of Old Testament prophecy and history. Not

much is said concerning the Sabbath in the pre-exilic books outside the Pentateuch. But in the few places where it is mentioned, we learn that the Sabbath was a day of abstinence from labor, Amos viii. 5; a day of special religious services in the temple, 2 Ki. xi. 5, 7, 9, cf. 2 Chron. xxiii.; the day of changing the shew bread, 1 Chron. ix. 32, cf. Mat. xii. 2 sq.; a day regarded as especially suitable for consulting a prophet, 2 Ki. iv. 23; a day associated in thought with the new moons and festivals, and their assemblies, Isa. i. 13; Hos. ii. 13 [11]; 1 Chron. xxiii. 31; 2 Chron. ii. 3 [4]; viii. 13; in fine, as a day which, in many ways, was regarded as set apart to Jehovah, and no longer belonging to a man himself. In fine, counting one or two severe laws of the Priest-code as police regulations, designed for Israel in camp rather than for permanent enforcement, the Sabbath of the Priest-code is, so far as appears from the particulars given, the same with the Sabbath of the other Pentateuchal codes, and the same with the Sabbath that appears in the history; and each differs, in principle, from the Sabbath of the scribes, in precisely the points in which that Sabbath-doctrine contradicts the teachings of Jesus.

The mention of the great sacred feasts that are said to have centred in the tabernacle, in the accounts of the pre-exilic times, is as full as could be expected. Aside from the passages that specify particular feasts, we have an allusion to Jehovah's yearly feast in Shiloh, Jud. xxi. 19; Elkanah and his contemporaries made annual pilgrimages to Shiloh, 1 Sam. i. and ii.; the appointed time of 1 Sam. xiii. 8, 11, may have been one of the festivals; the Chronicler represents that one principal object of David and Solomon in building the temple was to make provision for the feasts, 1 Chron. xxiii. 31; 2 Chron. ii. 4; the feasts are well known at the time of Solomon's death, 1 Ki. xii. 32, 33; they are prominent in the writings of Amos, Hosea, Isaiah, and Nahum, and in the Psalms, Amos v. 21; viii. 10; Hos. ii. 13 [11]; ix. 5; Isa. i. 14; xxix. 1; xxx. 29; xxxiii. 20; Nah. ii. 1 [i. 15]. Solomon is said to have observed the three feasts mentioned in the Pentateuch, 1 Ki. ix. 25; 2 Chron. viii. 13, both passages mentioning the "three times in the year," though the names are given in Chronicles only.

Besides the instances in which it is alluded to in connection with the other festivals, the Feast of Tabernacles is several times mentioned by itself. In Josh. viii. 35, the phraseology used is that of the law for the Feast of Tabernacles, Deut. xxxi. 10-12, and the suggestion is that the solemnities recorded in the previous verses took place at the time of the feast. In 2 Sam. xi. 11, Uriah says that the ark and Israel and Judah, but not the army, are dwelling in booths; on the face of it this looks like a celebration of the feast of booths. The feast of Jud. xxi. 19 had a vintage dance connected with it, and may well have been the Feast of Tabernacles, though if it was, the dance was a mere incident of it. Samuel was born "at the revolutions of the days," 1 Sam. i. 20, and the account connects an annual feast with his birth; the word translated "revolution" is used only here and 2 Chron. xxiv. 23; Ps. xix. 7 [6]; and Ex. xxxiv. 22, where "the revolution of the year" is the time for the feast of ingathering. The dedication of Solomon's temple was at the time of the Feast of Tabernacles, 1 Ki. viii. 2, 65-66; 2 Chron. v. 3; vii. 8, 9. This feast is very prominently mentioned in Zech. xiv. 16, 18, 19.

The writer on the TABERNACLE in the *ENCYCLOPEDIA BRITANNICA*, however, holds that this feast, though in existence from early times, did not become what is called the Feast of Tabernacles—that is, more properly, the feast of booths, as described in the priestly legislation—till the times of Nehemiah. He

says that from the passage beginning Neh. viii. 14, "we learn that the use of booths on that occasion had no foundation in traditional usage, but was based directly on the law, which then for the first time became generally known." But the passage does not say that the law then first became generally known. It does not intimate that the use of booths was an innovation on traditional usage. In a sentence constructed to throw especial emphasis on the adverb, the author of Nehemiah says that the children of Israel had not so done the thing since the times of Joshua; the fair inference is not that they had never done the thing before, but rather that they had always been in the habit of doing it, but never so conspicuously as on this occasion.

The writer of the article mentioned above further says: "According to the law in question, the booths were to be a memorial of the wilderness wandering, Lev. xxiii. 43, but of this there is no hint in Deuteronomy; and . . . it is certain from Exodus that the feast had originally agricultural and not historical significance." But the two are not necessarily exclusive; it is entirely credible that the agricultural significance may have had a historical meaning added to it, as the accounts say was the case. There is no need, therefore, to look for any custom of living in booths during the vintage, or of providing temporary shelter for those who came from a distance to the festivals, in order to account for the booths of this feast; the historical reason assigned for them is sufficient, though it does not exclude the other reasons, provided they are authentic.

The same author says: "In Jud. ix. 27 we find a vintage feast at Shechem among the Canaanites, from whom the Israelites first learned the ways of agricultural life, and from whom so much of the popular religion was copied." Here the intimation that the Feast of Tabernacles is a development from some Canaanite vintage feast is as gratuitous as the statement that the Israelites first learned agriculture from the Canaanites, or that much of the popular religion—meaning the religion of Jehovah, then counted correct—was copied from them. He further explains that the autumnal feasts of Israel, that finally developed into the Feast of Tabernacles, were originally held at many local sanctuaries, and that "it was the fame of great shrines that gradually tended to draw worshippers from a distance to temples like those of Jerusalem and Bethel. Finally, the Deuteronomic law of the one sanctuary . . . put an end to all local religious feasts," and "obscured the old significance of the festal cycle, and made room for the historical interpretation of the celebrations." This might be plausible if there were some proof that the feast in question was ever celebrated elsewhere than at the central sanctuary, but of such proof there is no vestige.

According to the Biblical accounts, as they now stand, the PASSOVER festival was instituted by Moses, just before the Israelites left Egypt, and was at that time kept by them, though in a primitive and incomplete form. Whether it superseded or incorporated any older festival usages, we are not informed, but certainly no one can trace any connection between the passover and the sacrifice to Jehovah which Israel asked Pharaoh's leave to make in the wilderness. If the writer of Ex. xii. 34, 39, was writing history, he certainly did not intend to be understood as here giving a different account of the origin of the feast of unleavened bread from that which he had already given in verses 3-28; verses 34 and 39 are rather to be understood as mentioning an incident that occurred, illustrating the haste with which the people left Egypt, and also illustrating how certain people, who had been negligent about obeying the command to put away leaven from their houses, were, after all, providentially compelled to eat unleavened bread.

The festival having been thus instituted, supplemental directions were afterward given, at different times, in regard to it, defining its position in the sacred year, its relations to the harvest, and its relations to the central sanctuary, and defining other points concerning it.

In contradiction to this, the articles on PASSOVER and PENTATEUCH in the *ENCYCLOPEDIA BRITANNICA* represent that this festival was, in its beginnings, a spring feast, arising from "the accumulation of the sacrifices of firstlings and fatlings" at that season; that "it appears from the Jehovist that something of this kind existed before the exodus, and gave occasion to the request of Moses for leave to lead the people out into the wilderness to sacrifice to Jehovah;" that the feast of unleavened bread was originally a different thing—an agricultural feast, presupposing a fixed residence in Canaan (as if they had no agriculture in Egypt); that up to the time of Josiah "this sacrifice was not tied to any set feast;" that the name *pesach* originally was probably that of some dance attendant on the feast, the historical idea now connected with it being a later interpretation; that the sacrifice of the lamb and the feast of unleavened bread became united into one in Josiah's time; that the feast underwent further modifications during the exile, and again after the exile. In proof that "the Deuteronomic passover was a new thing in the days of Josiah," is urged the passage beginning 2 Ki. xxiii. 21: "There was not made the like of this passover from the days of the judges who judged Israel, and all the days of the kings of Israel and the kings of Judah." But the difference between this particular passover and previous feasts of the kind, as we naturally understand by the context, did not consist in the fact that the feast itself, in the form in which it was now observed, was an innovation, but rather in the circumstances and the spirit of the observance.

Evidently, the view thus sketched is inconsistent with the Pentateuchal accounts. It is equally at variance with the statements of the other historical books. These inform us that the passover was celebrated shortly after Joshua crossed the Jordan, Josh. v. 10, 11; that it was one of the festivals of Solomon's time, 2 Chron. viii. 13; cf. 1 Ki. ix. 25; that it was prominent in Hezekiah's reform, 2 Chron. xxx. 1, 2, 5, 15, 17, 18, 13, 21. Confessedly, the books of Joshua and Chronicles know of no separation between the passover and the feast of unleavened bread, but use the terms together in their descriptions. Confessedly, the writers of 2 Ki. xxiii. and 2 Chron. xxxv. represent Josiah's passover to be of the genuine Mosaic type, not a new feast just contrived.

Under the outline found in the Pentateuch, every Biblical statement concerning the passover can be naturally placed, with no necessity for rejecting any of the testimony, or putting a forced meaning upon it. The account thus obtained will be found to be simple, intelligible, and consistent, and suited to the explanation of all incidental questions that arise on the subject. In contrast with this, the account found in the *BRITANNICA* article, based upon a proposed reconstruction of the Hexateuch, is complicated, involves improbable assumptions, and requires us to reject as false or impossible both a large proportion of the statements made in the Hexateuch itself, and many of the statements of the other books.

The Tabernacle as the Central Sanctuary. The three Pentateuchal laws concerning places of sacrifice are found in Ex. xx., in Lev. xvii., and in Deut. xii., supplemented by other passages in Deuteronomy. The first of the three, so far as its words go, neither restricts sacrifice to one place nor implies more places than one for it. This law is referred to

in Josh. viii. 31, where the altar on which Israel sacrificed was not the brazen altar of the tabernacle, but one reared for the occasion. Perhaps it is again referred to in 1 Ki. xviii. 30-32, where again the altar is not that of a central national sanctuary. On the supposition that both this law and the other two were given by Moses, this law is to be regarded as stating what was correct Israelitish usage up to the date when it was given, as regulating the usage from then to the giving of the subsequent laws, and as covering any cases that might afterward arise, which did not fall within the scope of the subsequent laws. The second in date of the three laws is that given in Lev. xvii., for, many assertions to the contrary notwithstanding, Deut. xii. distinctly presupposes Lev. xvii., instead of being presupposed by it; compare, for example, Deut. xii. 15 with Lev. xvii. 13, and so all through the two chapters. This second law is applicable to Israelites in camp or out of camp, but only when Israel is encamped around the tabernacle. It may have been enforced in the case of whatever guard remained steadily with the tabernacle during the thirty-eight years of the wandering, but it certainly was not enforced with the great body of the people during that time. In Deut. xii. 8, and context, the people at large are rather excused than rebuked for doing as they pleased, in contrast with sacrificing at a central altar only. After the settlement in Canaan, this law could have no application to the people in their homes, though it might apply if expeditions were made in which they took the tabernacle with them. The third sanctuary law is that given in Deut. xii. and subsequent passages.

Under this third law, Jehovah was to choose a place in the promised land, to put his name there, and the people were to come to this place from every part of the land, for certain acts of sacrifice and worship, and these they were forbidden to perform elsewhere. Obedience to this law would always be impossible, except when Israel was settled in Palestine, was at rest from enemies, and was in possession of a place which was recognized as the one chosen by Jehovah for the purpose. Accordingly, these three limits are explicitly stated in the law itself. Further, this law is qualified by an express permission to make private sacrificial feasts anywhere and at any time, provided due care was taken to prevent these from being confounded with the public rites that were limited to the central sanctuary, Deut. xii. 15, 21, with the context.

On the supposition that these three laws are all genuine precepts of Moses, we should expect to find the third law in constant operation in Israel in Palestine, unless conditions of political unrest existed that should render it infeasible, or unless a condition of things should arise in which no place was recognized as the one chosen by Jehovah to place his name there. Whenever either of these two conditions existed, obedience to the Deuteronomic law would become impossible, and usage in Israel would again become subject to the two earlier laws, as these might apply. In other words, all the laws alike recognize the place where the tabernacle and the ark are as the national centre of worship. But when the tabernacle and the ark are separated, or when either or both of them move from their permanent location, or when there is no permanent location for them, and they simply wander from place to place, these facts constitute modifications of circumstances that affect the applicability of the several laws.

As a matter of fact, the books of the Bible assert that the condition of rest was given by Jehovah to Israel in the time of Joshua, that Shiloh then became the abiding place of the ark and tabernacle, and therefore the national sanctuary, and remained so till the time of Eli or later, and that only Shiloh and Jerusalem ever held this position, Josh. xviii. 1, 8, 9, 10; xix. 51; xxi. 2; xxii. 9, 12; Jud. xviii. 31; xxi.

12, 19, 21; 1 Sam. i. 3, 9, 24; ii. 14; iii. 21; iv. 3, 4, 12; xiv. 3; 1 Ki. ii. 27; Ps. lxxviii. 60; Jer. vii. 12-14; xxvi. 6-9, with contexts. They represent, however, that the ark was sometimes moved from Shiloh, and that some respect was paid to the places that had been made sacred by the experiences of the patriarchs or of Israel in past times, 1 Sam. iv.; Jud. xx. 26-23; Josh. xxiv., especially ver. 26; 1 Sam. x. 8; xi. 14, etc. They further represent, however, that during a large part of the time from Joshua to David, and for the Northern kingdom after Solomon, the conditions of rest were not such as to render obedience to the Deuteronomic law possible; and that, for some portion of the time between Eli and David, there was no longer a recognized permanent place for the ark and tabernacle together. They represent that under David Jehovah again gave Israel rest, and chose a place to put his name there, and that, in pursuance of this, David placed the ark in Jerusalem, and the tabernacle near by, in Gibeon, thus constituting a divided central sanctuary, until the temple was ready to absorb the functions of both places, 2 Sam. vii. 1, 11; 1 Chron. xxii. 9, 18; xxiii. 25; 1 Ki. v. 4; 1 Chron. vi. 31, etc.; 1 Ki. viii. 44, 48, etc.; and the passages already referred to.

Parts of this account come from several independent witnesses. The account is perfectly continuous and consistent. Why should it not be believed?

In the article TEMPLE, in the *ENCYCLOPEDIA BRITANNICA*, we are reminded that there had been temples in Israel, both public and private, before that built by Solomon. The instances mentioned are the temple at Shiloh, and Micah's house of gods, Jud. xvii. 5. There might have been added the shrines at Dan and Ophrah, Jud. xviii. 30, viii. 27, and it ought to have been added that these places, with the exception of Shiloh, are mentioned with clear indications of disapproval. It is said that in the matter of the temple, "as in other matters, the Israelites must have learned from the Canaanites." But how does this follow? We are told that "in Solomon's temple both the oracle and the outer cella had folding doors," and that "the Chronicler (2 Chron. iii. 14) introduces a vail in the first temple," this being a feature of the post-exilic temple. But the folding doors do not necessarily exclude the vail. It is further said that "the first temple was primarily the royal chapel, and the kings did as they pleased in it; the second temple was the sanctuary of the priests." But several recorded instances, notably the rebellion against Athaliah, and the withstanding of Uzziah, 2 Ki. xi.; xv. 5; 2 Chron. xxiii.; xxvi. 21-23, show that the king's power in the first temple was limited; and the history throughout makes the first temple, no less than the second, the sanctuary of the priests.

Like these are all the attempts to prove that Israel had no proper central sanctuary until the times of Josiah. The historical notices of the successive kings from Solomon mention that the worship in the high-places was maintained; but they mention it with disapproval, so that each instance is an additional testimony to the fact that the law of the central sanctuary was obligatory throughout this period. Before Solomon many sacrifices and other acts of worship are mentioned as occurring at other places than the central sanctuary, and a plurality of legitimate altars to Jehovah are recognized as existing in the Northern kingdom, in the days of Elijah, 1 Ki. xviii. 30, xix. 14. But all these instances are explained, either as being illegal, or as being instances of the merely private sacrificial feasts that are provided for in the law itself, or as occurring in circumstances in which the law was inapplicable, and the usage was therefore governed by the earlier laws. In fine, there is no reason that will stand the test of true criticism for refusing to accept the Biblical account of the tabernacle and its functions as the central sanctuary of Israel, as historical and correct. (W. J. B.)

TAINE, HIPPOLYTE ADOLPHE, French critic and literary historian, was born at Vouziers, April 21, 1828. Before he left school he was marked as destined to achieve distinction. At the Collège Bourbon he gained the prize for rhetoric in 1847 and in the next year was at the head of those admitted to the Normal School of Paris. In 1853 he received the degree of doctor in letters, having presented a Latin thesis *De Personis Plutonicis* and a French *Essai sur les Fables de La Fontaine*. He then turned from the career of university teaching, which was open to him, and devoted himself to authorship. His *Essai sur Tite Live* (1854) was crowned by the French Academy, and his *Voyage aux Eaux des Pyrénées* (1855) achieved great popularity.

His *Philosophes français du XIX^{me} Siècle* (1856) was an attack on the system of education prescribed by the government. In 1863 he was appointed examiner in literature for the military school of St. Cyr, and in the next year professor of the history of art and aesthetics at the École des Beaux Arts. In the same year appeared his essays on English idealism with Carlyle as its exemplar, and English Positivism, with John Stuart Mill. These prepared the way for the work by which he is best known to the English-speaking world, *Histoire de la Littérature anglaise* (4 vols.). His brilliant sketch of the development of English literature and masterly criticism of its grand array of authors and their works would have sufficed to give it fame. But beyond and beneath, permeating and modifying all his research and statements, was the doctrine that the great authors, instead of being leaders of the thought of their age, were rather the product of its movement. The versatile genius of Shakespeare, the lofty verse of Milton, the correctness of Pope, the cynicism and even the madness of Swift, the romance of Sir Walter Scott, and the sweetness of Tennyson, are all attributed more to their physical and social environment than to individual originality. To the same effect he labored in his *Philosophie de l'art* (1865), in *Voyage en Italie* (2 vols., 1866), and in other works, brilliant in thought and style. In 1871 he delivered courses of lectures in England and received from the University of Oxford the degree of D. C. L. His closer views of England and its institutions were given in his *Notes sur l'Angleterre* (1872), which, like his other books of travel, has been issued in handsomely illustrated editions. Still more important than any of his preceding works was his great historical and political study of his own country, *Origines de la France Contemporaine*. To this belong *L'Ancien Régime* (1876); *La Révolution* (1878); *La Conquête Jacobine* (1881). In these works, while he depicted with unsparing hand the evils of the feudal despotism, he showed as little favor to the blood-thirsty democracy by which they were overthrown. The work, during its progress, was accepted as a partial defence of the monarchical system, and Taine, who had been rejected by the conservative Academy in 1864, just after the publication of his work on English literature, and again in 1874, was in 1878 admitted among the Forty Immortals.

TAIT, ARCHIBALD CAMPBELL (1811–1882), prime of England, was born at Edinburgh, Dec. 22, 1811, and educated at the High School there. He graduated at Glasgow University in 1827 and at Balliol College, Oxford, in 1830, where he became a Fellow and tutor. He opposed the new "Oxford movement," and with three others published a protest against Newman's famous Tract No. 90. His being in orders prevented his appointment in 1838 to the chair of Greek at Glasgow. In 1842 he succeeded Dr. Arnold as Head Master of Rugby School. While here he married and was widowed. Appointed Dean of Carlisle in April, 1850, he administered the office with much energy and efficiency; he was also an active member of the Oxford University Commission. After losing three children by scarlet fever he was

named Bishop of London in 1856, in succession to Dr. Bloomfield. In 1863 he initiated a plan to raise £1,000,000 in ten years for supplying the deficiency of church accommodations in London. After refusing the metropolitan see of York he accepted that of Canterbury from Disraeli in 1868, succeeding Dr. Longley. In this high office he displayed remarkable energy, honesty, tact, and courtesy. As a moderate Low Churchman he was disliked by the "advanced" party and continually attacked by the *Church Times*, but this he wisely disregarded. In the conflicts about ritual and ecclesiastical law his sound judgment was of great value. He presided over several important meetings, as the Pan-Anglican Synod at Lambeth, 1867; the Church Congress at Croydon, 1877; and the Conference of Anglican Bishops at Lambeth, 1878. His letter to the Evangelical Alliance at its meeting in New York, 1873, exhibited his liberal feelings. His writings are notable rather for common sense than for brilliancy or profundity. They include, besides various charges, letters, sermons, etc., *The Dangers and Safeguards of Modern Theology* (1861); and *The Word of God and the Ground of Faith*, in two parts (1863–4). He died at Croydon, Dec. 3, 1882. A sketch of his *Public Life* and a comparison between him and Archbishop Laud appeared the next year. A memoir of his wife and son, who both died in 1878, was written by W. Benham (1880), with his approval.

TAIT, PETER GUTHRIE, British mathematician and physicist, was born at Dalkeith, Scotland, in 1831. He was educated at the University of Edinburgh and at Peterhouse, Cambridge, where he was senior wrangler. He was made professor of natural philosophy in the University of Edinburgh, and is general secretary of the Royal Society of Edinburgh. He received in 1886 a medal from the Royal Society for his valuable contributions to mathematical and physical science. He is joint author with Sir William Thomson of the *Natural Philosophy* known by their name; and with Prof. Balfour Stewart of *The Unseen Universe*. He has also published *Recent Discoveries in Natural Philosophy*; *Dynamics of a Particle*; and *Quaternions*.

TALBOT, SILAS (1750–1813), naval officer, was born in Rhode Island, and at the outbreak of the Revolution was made captain in a R. I. regiment. He served at the siege of Boston, at New York city, and at Fort Mifflin, near Philadelphia. In 1778 his nautical skill was displayed in transporting Gen. Sullivan's troops from the main-land to Newport, R. I., and in capturing the British floating-battery near that town. In 1779 he armed a prize vessel, and after several exploits was commissioned as captain. He was, however, captured by a British fleet in 1780, and remained a prisoner till the close of hostilities. He purchased the forfeited estate of Sir William Johnson, on the Mohawk, and served in the N. Y. Legislature and in Congress. On the reorganization of the navy in 1794 he superintended the construction of the frigate Constitution, which became famous as "Old Ironsides." In this vessel he cruised in the West Indies in 1799. He resigned in 1801, and died at New York, June 30, 1813.

TALC, an important species of mineral, of unctuous feel, whence possibly its name, which is derived from the same root as English "tallow." Chemically talc is a silicate of magnesia, usually somewhat hydrated, its formula being $O_{10}Si_4Mg_3 \cdot 2H_2O$. Occasionally it makes up the mass of extrusive geological formations. In physical character it is very soft, ranking with graphite in this particular, and is used as No. 1 in the scale of hardness. Specific gravity, 2.6 to 2.8. It is found in several conditions, occasionally in an imperfectly crystallized state, but usually in compact or in foliated masses. The folia are micaceous in character, very flexible but not elastic. Talc is sometimes of pearly lustre, usually light green in color, but occasionally white or dark green. In its compact or massive

variety it is known as steatite or soapstone. Extrusive beds of this material occur in some localities of the United States, often in association with serpentine and talcose or schloritic schist. Quarries of soapstone are worked at several localities in Vermont, New Hampshire, and Massachusetts; near Philadelphia, Baltimore, and Washington, and at many other places. It is used to make stoves, ovens, and hearths, for sizing rollers in cotton factories (being unaffected by acids), as stoppers for chemical vessels, in its powdered state as a lubricant, and for slate pencils and crayons. The French chalk of the toilet and tailors' shops is a soft white sort of soapstone. It is used to some extent in the porcelain manufacture, and is an ingredient in several kinds of steam-packing. Being easily cut into figures which can be hardened by fire, it is used to imitate more valuable stones, being colored in accordance therewith. At the town of Edwards, St. Lawrence co., N. Y., is a large deposit of talc which is peculiar in having the fibrous character of asbestos. This material is crushed and pulverized, and is used for a variety of purposes, but principally in paper-making. As a filler in the manufacture of paper of all grades, except the very finest and the coarsest, it is excellent, and is preferred to the clays and other substances ordinarily used for this purpose. (C. M.)

TALLMADGE, BENJAMIN (1754-1835), colonel in the Revolutionary war, was born at Setauket, L. I., Feb. 25, 1754. The son of a minister, he graduated at Yale College in 1773, and had charge of a high-school at Wethersfield, Conn., when the war began. Entering the army as lieutenant in 1776 he rose to the rank of colonel in 1779. In September of that year he crossed Long Island Sound and surprised and captured 500 Tories. In the following May a similar exploit resulted in the destruction of British stores at Fort George, L. I. He had the custody of Major André after his capture in September, and was a member of Washington's military family. After the war he married the daughter of Gen. William Floyd (1734-1821), a signer of the Declaration of Independence, who had commanded the patriotic militia of Long Island. He settled in New York city as a merchant and in 1800 was elected to Congress, where he served for sixteen years. He died at Litchfield, Conn., March 7, 1835, having long commanded universal respect as a survivor of "the times that tried men's souls."

His son, FREDERICK AUGUSTUS TALLMADGE (1792-1869), lawyer and politician, wrote *Memoirs* of his father (1859), held many local offices, and was a member of Congress (1846-48).

TALMAGE, THOMAS DE WITT, Presbyterian preacher, was born near Bound Brook, N. J., Jan. 7, 1832. He graduated at the University of New York City in 1853 and at New Brunswick Theological Seminary in 1856. He was then ordained pastor of a church at Belleville, N. J. In 1859 he was called to the Reformed Church, Syracuse, N. Y., and in 1862 to the Second Reformed Church, Philadelphia. After seven years' service here, he became pastor of the Central Presbyterian Church, Brooklyn, N. Y. His brilliant oratory soon drew crowds, to accommodate which a new edifice of wood and iron, capable of holding 3000 people, was erected, and when it was destroyed by fire, Dec. 22, 1872, a more substantial one was built of brick and stone on the same site. It has seats for 5000 persons. The old church is used as a Lay College, of which Dr. Talmage is president. Besides gathering and ministering to one of the largest Presbyterian churches in the country, he has been a popular lecturer, a writer for newspapers, and editor of a religious weekly and a magazine. Quick in movement, often extravagant in style, and energetic in action, he readily sways an American audience. His sermons are widely circulated every week, over 600 newspapers publishing them entire. They are translated into several languages. From his sermons

and contributions to the press many popular volumes have been compiled. Among them are *Crumbs Swept up* (1868); *Abominations of Modern Society* (1872); *Night Sides of City Life* (1878); *Brooklyn Tabernacle* (1884); *Marriage Ring* (1886).

TAMMANY SOCIETY, a noted political organization of the Democratic party, derives its name from Tamanend, an Indian chief, concerning whom various legends are related. He is said to have ruled near the present site of Easton, Pa., to have signed the treaty with William Penn, and after a life of primitive piety to have died a centenarian. Towards the close of the Revolutionary war the Pennsylvania troops of Washington's command took him as their patron saint instead of St. George, and celebrated his day, May 12, with festivity appropriate to his race and the season. The warriors, decked with feathers and bucktails, having gathered around a liberty pole, "St. Tammany" came forth from a wigwam, and gave them a "talk" on courage and freedom, after which they danced and caroused. The annual celebration was retained in the American army and among the people, especially in Pennsylvania, for many years. Within a fortnight of the first inauguration of Washington at New York, April 30, 1789, William Mooney, an ardent Irish-American "Liberty Boy," took advantage of this festival to institute the Columbian Order. It was intended as a popular offset to the "Society of the Cincinnati" (q. v.), which had excited prejudice on account of its supposed aristocratic character and tendencies. The immediate cause of the formation of the new society was the popular reaction against the recent removal of the political disabilities of the wealthy Tories who had remained in New York city. Columbus had been selected as the patron of the order, probably in deference to Joel Barlow's once famous epic, *The Vision of Columbus*, then newly published. But the terms and usages of the society were all derived from those of the Indian tribes, and when the popular instinct transferred the honor to the Indian Tammany the leaders readily acquiesced in the change. Mooney, as "Grand Sachem" of the order, was assisted by twelve sachems, or chiefs of tribes, and the other officers were a sagamore, or master of ceremonies, a wiskinkie, or doorkeeper, and a scribe. Pres. Washington is said to have availed himself in 1790 of the assistance of the society in entertaining a delegation of Creek Indians and negotiating a treaty with them. At this time some Federalists belonged to it, but its rules and levelling tendency soon excluded all but pronounced Republicans. The passage in Washington's "Farewell Address" referring to the danger of political "combinations and associations" has been thought to refer to the Tammany Society, and had the effect of diminishing its membership at the time.

The society had indeed become a "machine" under the direction of Aaron Burr, who, though never a member of the order, was able through his personal influence with Mooney and its other leaders to inspire and guide its movements in the political struggle in New York city. By its aid he achieved in 1799 the astonishing defeat of the careless Federalists in both city and State. His victory promptly secured for him the nomination to the vice-presidency from the Congressional caucus, but his shameless attempts to snatch the presidency from Jefferson brought him discredit with the party he had guided to success at the polls. Yet in 1804, when he sought to regain his prestige by winning the governorship of New York by a similar method, Tammany, whose members had received no benefit by his elevation, still adhered to his cause. Burr, defeated by the efforts of Hamilton, slew him and was himself ruined.

The society which he had made formidable in politics still professed to be organized for charitable purposes and obtained a charter in 1805 as the "Tammany Society, or Columbian Order." It even began a museum of natural history, which finally passed into the

hands of the great showman Barnum. But such ideas were soon discarded by its practical members. One of its main objects was the extension of the elective franchise which had been restricted in the New York State Constitution to freeholders of a certain amount of real estate. Yet actually for many years it did nothing to secure this object, its energies being absorbed in the contest with De Witt Clinton, who had at one time been its scribe but had been alienated by its subservience to Burr, and its later alliance with the Livingston family, noted for its wealth in land. Throughout Madison's presidency there was a rivalry between him and the Clintons—"old George," the vice-president, and his greater nephew De Witt—having some elements of that between Jefferson and Burr. From Madison Tammany obtained the control of the Federal patronage, while at Albany Daniel D. Tompkins—early and late a member of the society—was now governor of the State. In 1811 Tammany had reached such financial success that it built its first hall. Its meetings had heretofore been held in taverns, and especially in Martling's Long Room, a one-story structure built for dancing parties.

After the war with Great Britain (1812-15) De Witt Clinton, who was supposed to be completely crushed by his political enemies, renewed his grand project of the Erie Canal with such vigor that the people elected him governor though Tammany showed its spite by naming an opposition candidate. The society however had gained a powerful ally in Martin Van Buren, and in a number of instances it was enabled by his shrewd management to win political advantages and even to appear more favorable to internal improvement, support of which was the ground of the governor's popularity. A general meeting in Tammany Hall in 1820 led to the State constitutional convention which in 1821 removed some of the restrictions on the elective franchise which had been one of the society's earliest grievances. The society itself was correspondingly enlarged and became too unwieldy to conduct affairs by general meetings. In 1822 a general council was therefore formed, consisting of three delegates from each of the eleven wards. This council, or general committee as it came to be called, gradually assumed the powers of the general meeting, and the society merely preserved its existence for ownership of the hall and formal celebrations.

Before De Witt Clinton died in 1828 he had again been elected governor of New York in spite of his able and vigilant foes, but thereafter Tammany Society worked in harmony with the Democratic governors for many years. In 1833 New York city had obtained a charter making the mayor elective, and a change which produced increased political activity among the people.

The "Equal-rights" party struggled with the Tammany managers for control of the general meeting. An incident of the meeting in 1835 gave the name "Locofoco" to these innovators and the name was afterwards extended to the whole party. Tammany was defeated more than once by the Locofoco in local contests, but in 1839 harmony was re-established. The Democrats however were defeated in 1844, when James Harper was elected mayor by the American party. When the Democratic party of the State divided into the "Hunkers" and "Barnburners" (*q. v.*) a somewhat corresponding division took place in Tammany Hall between the "Hards" and "Softs," the former being the office-holding faction. Though they united in electing Fernando Wood mayor in 1854, the internal struggle continued. In 1858 with the regular Tammany nomination he was defeated and in the next year in opposition to it he was elected. He began the system of lavish municipal expenditure which had such disastrous results soon after the civil war.

In 1860 the first Tammany Hall was reconstructed, but on July 4, 1867, the corner-stone of the present building on Fourteenth street between Irving Place and Third avenue was laid and Gulian C. Verplanck de-

livered the oration. Exactly one year later the building was opened to receive the Democratic National Convention which there nominated Horatio Seymour and Frank P. Blair. The building is of red brick with white marble trimmings. It has a wide front and is three stories high. A circular pediment bears the inscription "Tammany Society," with the dates 1789 and 1867. Between these in a niche is the marble statue of an Indian warrior, twelve feet high.

The delegates to the general committee originally came from each ward, but in 1843 from each election district and finally from each precinct. The body thus grew from 33 members to over 1400, and from having management of the campaigns to having entire control of the political action. The society still owned the hall and held formal celebrations but had hardly the semblance of power. Even the general committee was too unwieldy for its nominal task and a "committee on organization" did the serious work. The chairman of this committee was the "boss" of the Hall.

After the civil war came a succession of "rings" controlling the action of the Hall. The most notorious of these was the corrupt combination formed by Wm. M. Tweed, A. Oakey Hall, Richard B. Connolly, and Peter B. Sweeney. Having obtained from the State Legislature an amended city charter, which gave them as office-holders irresponsible control of the city finances, they doubled the annual expenditure, and increased the bonded debt by more than \$100,000,000. A standing army of voters was obedient to their will exercised through the agency of Tammany Hall. After years of wholesale speculation and embezzlement, a clerk revealed to the *New York Times* the fraudulent accounts. Even after their exposure, Boss Tweed could arrogantly ask, "What are you going to do about it?" A committee of seventy, with the aid of Charles O'Connor, Samuel J. Tilden, and other prominent Democrats, undertook to battle with the ring and by heroic efforts succeeded in ousting its members from office and driving them into exile or into prison.

Yet Tammany Hall survived even this catastrophe. In 1873 it passed into the control of John Kelly, a nephew of Cardinal McCloskey, who had assisted in expelling the Tweed Ring. Personally pure and without ambition for office, he was an astute and successful political manager. The new nominations were of a higher order than had been customary for many years. But the growth of the Independent vote and the various Democratic secessions from Tammany had diminished its power. As economic questions again became prominent, the Democratic party moved in the direction of Free Trade, while Tammany inclined to a protective tariff, claiming room for that policy under the shield of Democracy. In 1879 Tammany bolted from the action of the State convention and made John Kelly its candidate for governor, thus defeating Lucius Robinson. In 1880 its influence was used against Gen. Hancock in the Presidential campaign. It endeavored to prevent Cleveland's nomination and election in 1884, but without success. Kelly's health failed and he was obliged to withdraw from political work. He died June 1, 1886. No one has succeeded to his power. But Tammany Hall still remains the most compact organization of the Democratic party in New York city. Hon. Abram S. Hewitt, though not belonging to it, was elected mayor of New York on its nomination in 1886, but, as his subsequent course gave offence to its members, he was defeated when a candidate for re-election in 1888, and H. J. Grant, Tammany's candidate, secured the prize. (J. P. L.)

TANEY, ROGER BROOKE (1777-1864), chief-justice of the United States, was born in Calvert co., Md., March 17, 1777. He belonged to a Catholic family, which had settled there a century earlier, and always adhered to his ancestral faith. He graduated at Dickinson College in 1795, and was admitted to the bar in 1799. In the next year he was a member of the Mary-

land house of delegates, and in 1816 of the State Senate. His reputation as a lawyer steadily increased, especially after his removal to Baltimore in 1823. He had originally been a Federalist, and was personally opposed to slavery, but in the new alignment of parties, which took place during John Quincy Adams' administration, Taney took the Democratic side. He was appointed attorney-general of Maryland in 1827, and four years later Gen. Jackson called him to be U. S. attorney-general, and found him an able assistant and trusty adviser. When the President, after vetoing in 1832 the bill for renewal of the charter of the U. S. Bank, decided further that the bank and its branches should no longer be government depositories, Duane, then secretary of the treasury, with a well-grounded apprehension of the result of intrusting the funds to State banks of various and uncertain degrees of financial soundness, refused to execute the order. He was, therefore, removed, and Taney, who had advised the scheme, was appointed in his place. The nomination was held in suspense by the Senate for nine months, and finally rejected, though Taney had meantime been acting as head of the department. Jackson's regard for him was shown again in 1835, when he nominated Taney first as associate and afterwards on the death of John Marshall as chief-justice of the Supreme Court. There was still opposition in the Senate, but within three months Taney was confirmed. He had now attained the height to which his ambition had early aspired. The feelings of awe and veneration which, during the long career of Chief-Justice Marshall, had gathered around the Supreme bench, were preserved during several years of Taney's term.

Two great cases bearing strong impression of his mental qualities illustrate his powers and balance of mind at its period of most full development and in its days of declining strength. Both of these cases involved fundamental questions relating to the structure of our system, the one as it regards its political and the other its civil aspects. One of these cases arose out of what is known as the Dorr rebellion, which was an attempt to change the constitution of Rhode Island by popular authority without the assistance and concurrence of the then existing government of that State. The other case was that of the status of a slave who had been carried from a State in which slavery existed to a place where that institution did not exist and returned to the first-mentioned State, where the freedom of the slave was claimed on the ground that he had been taken by his master to a State in which slavery had no existence. In the first case the decision of the court rendered by the chief-justice was strictly confined to the necessities of the questions presented, while in the other the opinion of the chief-justice went beyond those necessities to define a grave constitutional question that involved the balance of powers between the national government and the States.

That the attempt to change the constitution of Rhode Island, independent of any concurrent action of the existing government, was revolutionary in its nature appears quite clear. That the government sought by such means to be established was not in fact established so as to be capable of being regarded as a *de facto* government appears by the statement of the case, and is a recognized historical fact. The case in the opinion of the chief-justice turned upon the authority of the President upon the application of the government of a State to use the military power of the United States to quell insurrection against such State authority, in such a case the court being concluded by the action of the President on such an application. As in cases of that character it may happen that the actual existence of the government making such a demand of the President may be disputed as between two conflicting claimants to such authority the conclusion of the court would appear to sustain the

idea that the determination of such a question belongs to the President, and his decision is binding upon the court. No higher assertion of national authority can be made than that which confers upon the national government authority to determine the controversies between a State and its citizens as to the rightful exercise of State authority, and where such authority is accorded to the national executive so as to bind the judicial power, the assertion of national prerogative against State authority is as vigorous as the most ardent advocate of the national idea could demand.

But the greater the manifest regard of the American people for its highest tribunal the more anxious were the pro-slavery politicians to obtain the support of this department of the government for the movement for the extension of slavery. The case of *DRED SCOTT* (*q. v.*) furnished the opportunity, and Taney, with the majority of the court, yielded to the pressure. The decision which refused Scott, as a negro, any standing in a U. S. court, and the offensive dictum that, in the opinion of the framers of the U. S. Constitution, negroes had "no rights which white men were bound to respect," was published March 6, 1857, immediately after Pres. Buchanan's inauguration. It was evidently intended by its authors to extinguish all opposition to the progress of slavery in the national domain; its only effect was to rouse in the North a fiercer and more determined antagonism to the domination of the slave power. During the ensuing years of political strife, secession, and civil war Taney remained a reluctant witness to the steady progress of a political revolution, which finally overthrew slavery even in Maryland. He faithfully performed all the duties of his office as he understood them, but he bewailed the loss of much of its former glory. His views even brought him into conflict with the military authorities, and he was compelled to recognize the truth of the proverb, "*Inter arma leges silent.*" He died at Baltimore, Oct. 12, 1864. His life ended before the conclusion of the great struggle that restored the strength of the national authority that had been weakened by the decision in the Dred Scott case, and the country truly mourned the death of an eminent judge and worthy man who was equal to the demands of his great office in the height of his mental powers, but in the end could not resist the course of nature and of revolution. See his *Life* by S. Tyler (1872).

TAPPAN, ARTHUR (1786-1865), merchant and Abolitionist, was born at Northampton, Mass., May 22, 1786. His father, Benjamin Tappan, had been noted for his patriotism during the Revolution. Arthur, after receiving a common-school education, entered on a mercantile career at Boston. With his brother, Lewis, he engaged in importing dry-goods, and resided for a time at Portland, and afterwards at Montreal. The war of 1812 compelled him to leave Canada, and he settled in New York. Here his activity and liberality found wide scope in founding and contributing to religious and benevolent enterprises. The American Tract Society, the American Bible Society, and various colleges and seminaries were fostered by his generosity. In 1828 the Tappan brothers founded the *New York Journal of Commerce*, with Horace Bushnell as one of its editors. Arthur was roused to activity in the Abolitionist cause by the persecution of William Lloyd Garrison, whom he rescued from a Baltimore jail by paying his fine. In 1833 he called at his own house a meeting for the formation of an anti-slavery society, and in the same year was made the first president of the American Anti-slavery Society. When threatened with the loss of Southern trade the brothers replied that their goods but not their principles were for sale. In 1834 Arthur's dwelling-house was attacked and pillaged by a mob, and the brothers' store had to be defended by arms. Yet they continued to give liberally to the Abolition cause until in 1835 their warehouse was burned. By

severe struggles the firm was able to maintain its standing, even during the panic of 1837. When the leaders of the Anti-slavery Society directed their attacks on the Christian churches as upholders of slavery Arthur Tappan protested, and finally withdrew from being its president. In 1841 his business partnership was dissolved, and in the next year he failed, but with unflinching integrity caused all his personal property to be sold for the benefit of his creditors. He was then employed by his successors in the business until 1849, when he joined his brother in his enterprise, the first mercantile agency in the United States. In old age he resided at Passaic, N. J., and finally at New Haven, Conn., where he died July 23, 1865. His brother Lewis (1788-1873), who had been closely associated in his business and philanthropic labors, wrote his *Life* (1870).

Another brother, BENJAMIN TAPPAN (1773-1857), in his youth learned engraving and portrait painting, but afterwards studied law and moved to Ohio in 1799. There he was a member of the Legislature, afterwards judge, and in 1833 was appointed by Pres. Jackson U. S. district judge. In 1839 he was elected to the U. S. Senate as a Democrat, but in 1848 he took part in the organization of the Free Soil party. He died at Steubenville, Ohio, April 12, 1857.

TAPPAN, HENRY PHILIP, metaphysician and educator, was born at Rhinebeck, N. Y., April 23, 1805. He graduated at Union College in 1825, studied theology at Princeton, and became associate pastor of a Reformed church at Schenectady. In 1828 he was called to a Congregational church at Pittsfield, Mass., and in 1832 was made professor of moral philosophy in the University of the City of New York. After holding this position six years he conducted a private school for 14 years. Meantime he had prepared his metaphysical treatises, commencing with a review of *Edwards on the Freedom of the Will* (1840), and expanded into *The Doctrine of the Will Determined by an Appeal to Consciousness* (1840), and *The Doctrine of the Will Applied to Moral Agency and Responsibility* (1841). He also published *Elements of Logic* (1844), which was afterwards revised. In 1852 he was chosen first chancellor of the University of Michigan, and made a tour in Europe, recorded in his book, *A Step from the New World to the Old* (1852). Another visit to Europe enabled him to secure an excellent equipment for the university observatory, and the services of Prof. Francis Brünnow as astronomer. The university soon attained great prosperity, and became the model for similar institutions in other States. In 1863 Dr. Tappan resigned and went to Europe.

TAR is a result of the destructive distillation of organic substances, especially wood (See Vol. XXIII, p. 57 (p. 62 Am. Rep.)). Where wood is plentiful tar is produced by burning the wood for that purpose; and in some of the pits where charcoal is produced an arrangement is made by which the tar is collected. From wood-tar there is further distilled wood vinegar, or pyroligneous acid, from which is also procured wood naphtha. In the United States nearly all of the wood-tar comes from North Carolina. Wood tar is produced by the smothered burning of the long-leaved pine deadened by fire. A tar-kiln is commenced by scooping out of the ground a saucer-shaped foundation, making a hole in the middle, and thence running a wooden spout outside the rim of the foundation. The wood is split into billets 3 or 4 feet long and about 3 inches in diameter. The billets are stacked in the centre hole and piled upward, each upper stick lapping a little over, thus giving the finished pile the appearance of an inverted cone. Logs of wood and green twigs are then piled around, and the whole covered with earth. The fire is lighted at the top eaves, and the distilled tar runs out through the spout. A kiln yields 50, 100, or more barrels of tar, according to its size. Large iron retorts have been used, but the product is not suffi-

ciently greater or more cleanly to pay for increased cost.

Coal-tar was for a long time a troublesome product of gas-works, no useful application of it being known to any great extent. Later it was used as a covering to protect iron-work exposed to the weather; and the pitch obtained by distillation was found, when mixed with earthy matters, to be a good substitute for the natural product, asphaltum, used for artificial pavement, water-tight covering for roofs, etc. Finally tar distillers learned to extract from it crude naphtha, and also light oily fluids. The pitch, by continued distillation, was made to yield more oily matters. Crude naphtha is now purified with it; by taking one-tenth its bulk with concentrated sulphuric acid, adding when cold 5 per cent. of peroxide of manganese, and distilling off the upper portion a rectified naphtha is obtained, which easily dissolves India rubber. Mixed with wood-naphtha it produces a powerful solvent of various resinous substances useful in making varnishes. Still further purified, the liquid benzole is obtained, used extensively as an illuminating agent. The light essential oils, as well as the heavier ones, possess antiseptic properties, which render them valuable for preserving wood from decay. Among the other products obtained from coal-tar are carbolic acid and the aniline colors.

(F. G. M.)

TARIFF (from *Tarifa*, the name of the Spanish port at which the Moslem rulers of the country levied duties on goods passing through the Straits of Gibraltar) is a list of the duties levied by any country upon exports and imports, especially the latter. In the United States question of free trade or protection has centred around the legislation to increase or lower these duties; and the tariff controversy has stood next to that over slavery, and above that over the currency, as a source of party divisions.

The word was in America adopted from English usage. The early English tariffs were prohibitory in their provisions. They absolutely forbade the importation of articles which the Parliament agreed should be made at home. It was not until the reign of Queen Elizabeth that the use of the tariff as a source of revenue to the government may be said to have begun. Heretofore the sovereign had profited by it only through selling dispensations from its provisions to favored merchants, such as Napoleon did during the continuance of his Continental system, but without the concealment he practised. But even the tariffs of a later date contained distinct prohibitions, and that of 1819 still continued the prohibitory method under the cover of duties placed so high as to effect the exclusion of the article. In the American tariff there are no prohibitory duties except on some articles—chicory, shoddy, doctored wines, etc.—which are excluded for other than merely commercial reasons.

After American independence had been secured the power to legislate with reference to duties on imports passed to the thirteen States of the very imperfect Union of 1777-89. Each of them adopted such a tariff as suited its ideas and circumstances, and the lines of custom-house collections sundered them from each other. This at one time seemed not unlikely to result in the dissolution of the Union into its original elements, as quarrels sprang up in all quarters, and some States were not above adapting their regulations to foster smuggling into the territory of their neighbors. The Constitution of 1787-89 transferred this power to the new national government, and on July 4, 1789, James Madison reported a tariff law, which expressly stated among its objects "the encouragement and protection of manufactures."

While the Federalist party continued in power the only changes made in this tariff were in the increase of its duties; but on the accession of the States Rights party in 1801 there was a cessation of this constant adaptation of the duties to the freshly discovered needs of industry. No duty, however, except that on

salt, was repealed or even reduced, and when the second war with Great Britain occurred the duties were doubled until three months after the cessation of hostilities. In this first period of our tariff legislation there was entire agreement among our statesmen as to the wisdom and propriety of the protective policy, Washington and Hamilton on the one side, and Jefferson and Madison on the other being of that mind. At the same time there was prevalent a very moderate idea of what the country should undertake in the way of supplying itself with manufactures, and the tariff omitted or placed under a mere nominal duty some of the most important staples.

It was the war of 1812 which at once destroyed the previous unanimity of view and raised the ideas of the protectionists as to the necessity and feasibility of a national manufacturing system, which would make the country independent of foreign supplies in case of another war. The war itself acted as a prohibitory tariff on British goods, and forced Americans to begin making for themselves what they had been buying abroad. It created the factory system on American soil, and thus began the supersession of those household manufactures which had clothed our people. At its close the people of the Middle and Southern States were pretty well united in the belief that it would be a mistake to allow the industrial gains of the war to be sacrificed to the competitions of cheaper labor and more abundant capital in Europe; and the tariff of 1816 was enacted, in the face of the resistance of New England, with that purpose. It proved quite inadequate, as its duties were too low to meet the new conditions as to cheapness of production and of transportation in Europe, and it was reinforced by higher duties in 1824 and 1828, the latter being the highest tariff ever enacted in this country.

In the meantime the South and New England had changed places as regards the principle of a protective tariff, the former because manufactures were found impracticable in slave States, the latter because it had begun to divert its capital and the ingenuity of its people from an exclusive devotion to commerce and shipping to manufactures. In both 1824 and 1828 the amount of opposition from the South had increased, and in the next decade that section had become almost unanimous for free trade. This was especially the case after England in 1832 removed the protective duty she had levied upon our cotton for the benefit of her East and West Indian dependencies, as she had found that our longer and finer staple was indispensable to her spinners if they were to compete with those of America. From that time the Southern planter no longer depended upon the Northern mills for a market for his crop; and he entered into a free trade alliance with the English loom-lords for mutual advantage.

In 1832 the tariff was revised, and many of its duties were reduced to conciliate the growing opposition, but the result was so little acceptable to the South that South Carolina, with some moral support from her neighbor States, undertook to "nullify" the tariff laws of the United States, and to prevent the collection of their duties in her ports. By the firmness of Pres. Jackson this danger was averted; but for political reasons a further revision was had in 1833, and it was agreed that there should be a progressive reduction of duties until by 1842 none of them should stand higher than 20 per centum *ad valorem*. This reduction proved disastrous to our manufactures, and was a leading cause of the panic of 1837, which caused a political revolution and brought the Whigs into power in 1841. The tariff of 1842 ranks in protective efficiency beside that of 1828, and it caused a revival of American industries in all directions.

In June of 1846 Great Britain repealed its corn laws and abandoned the protective principle, after enjoying its benefits for more than 500 years. It was predicted and confidently expected by Mr. Cobden and his associates in the League that this would be followed by the

speedy adoption of free trade in all parts of the civilized world. In the United States it did lead to the tariff of 1846, which placed almost all duties at one of three *ad valorem* levels of 10, 20, or 30 per centum, instead of the specific duties of the tariff of 1842. It is notable that Mr. Calhoun suggested as preferable the sliding-scale method, by which duties should rise as prices fell and *vice versa*, as tending to reduce instead of increasing fluctuations in prices, and also to give American manufacturers a better chance. The tariff operated very unevenly upon our manufactures, as some of them still enjoyed ample protection, while others, especially those of iron and woollen goods, were greatly depressed, and in many cases ruined. Presidents Taylor and Fillmore urged a return to protective duties on the ground of the harm the industries of the nation had received; but the slavery controversy occupied the time and attention of Congress to the exclusion of almost everything else. In 1857 the Southern leaders even carried an amendment to a bill for a slight alteration in tariff methods, which reduced the duties by 25 per centum. This was followed by a panic, of which it was a chief cause; but although Pres. Buchanan urged the revision of the tariff in the interests of our native industries his recommendations passed unheeded, until at the close of his administration the withdrawal of Southern senators and representatives of the seceding States left the Republican party with a majority in both branches of Congress, and this led to the adoption of the protective tariff of 1861, called the Morrill Tariff from its chief author, Hon. Justin D. Morrill.

When this tariff was adopted six States had declared themselves out of the Union, Jefferson Davis had been inaugurated as President of the Confederate States at Montgomery, and nine days afterwards the Constitution of the Confederacy was adopted, declaring that its Congress should have no power to impose protective duties on imports. The tariff of 1861 was a war measure both in the sense of levying many duties for the sake of a large revenue to the national government, and in the sense of aiming to put the country in a posture of defence in case of any complication with Europe. It was altered by the imposition of higher duties in the session of 1861-62 and in that of 1863-64, and in a minor degree at various other times. Throughout the period protection and revenue were equally kept in view, and through its operation both these were secured. The manufacturing industries grew and the natural resources of the country were developed with such rapidity, and the losses of population were replaced by immigration to such an extent, that the terrible waste of war was hardly felt in an economic sense, and the country came out of the most gigantic civil conflict known to history richer and stronger than when it began.

With the close of the war and the reduction of the burdens of national indebtedness, the work of bringing the tariff from a war to a peace basis began. First, revenue duties, such as those on tea and coffee, were repealed. Then as the internal revenue taxes were repealed, duties raised to compensate them were reduced correspondingly. This was effected especially in 1870; but in 1883 a general revision was effected after a thorough investigation of the workings of the tariff through a national commission. But the accumulation of a surplus of revenues in the national treasury brought up the question of a further revision and reduction, and the majority of the House in the Fifth Congress committed itself to that policy by passing the Mills Bill, so called from its author, Hon. R. Q. Mills.

As Pres. Cleveland had urged this policy very strongly upon Congress in his annual message of December, 1887, and was known to have expressed his approval of this particular measure, and became a candidate for re-election to the presidency in 1888, the election campaign of that year was accepted on both sides as turning upon this issue. An especial feature

of the Mills Bill was the transfer of raw materials of manufacture to the free list. This change may be regarded as having secured to Mr. Cleveland the votes of two manufacturing States in the North. But as he got no more than these, and as the agricultural States of the North-west showed their resentment of this proposal by their votes, the Mills Bill and the policy it embodies may be said to have shared in Mr. Cleveland's defeat. In those sections of the South where manufactures had struck root since the abolition of slavery there was a notable falling-off in the vote of the Democratic party, and both Virginia and West Virginia gave Mr. Cleveland only small pluralities. At the same time the Protectionists secured majorities in both branches of the Fifty-first Congress, thus enabling them to proceed with the work of reconstructing the revenue legislation of the country in accordance with their principles.

In the later phases of the tariff controversy the opponents of the protectionist policy have shown themselves very unwilling to be called free traders. Some of them seem to think they are entitled to repudiate this now unpopular name because they do not wish to abolish the custom-house, as do John Ruskin and Henry George, but rather to maintain a tariff for revenue. But this wish is not in the slightest degree inconsistent with the idea of free trade, in the well-ascertained and historical sense of that word. A tariff which should impose no duty calculated to divert any part of the labor and capital of the country into a channel in which they would not flow otherwise is a free trade tariff, however high its duties, or however large a share of the national revenue may be derived from it. Such a tariff will either levy duties only on such articles as cannot be produced in that country, or it will compensate the duties upon other articles by excise taxes upon the domestic product of equal amount. Under such a tariff trade would be as "free" as if there were not a custom-house in the whole country.

More legitimate is the objection to the term free trade in the case of those who say that while they believe in free trade principles, they recognize the vested rights which have grown up under the protective tariff, and they would do nothing to injure the manufactures thus called into existence, while they would move slowly but steadily towards a system of "industrial liberty," and would refuse to vote for any further extension of protection either in the imposition of new duties or the raising of old ones. But this species of "revenue reformer" is rarely met with, and has not a single known representative among the economists or the statesmen of the country.

The protectionist principle is not limited to any method of application. If it were possible to accomplish the same end by premiums or exemption from taxation or guarantee of profits, there would be no objection to the substitution of those methods. But it is found in practice that each of these is attended with difficulties which do not attend the adoption and enforcement of a protective tariff.

There are three methods of levying the duties of a tariff: (1) By taxing imports a given percentage of their value, and ascertaining this by the invoices, or by the judgments of experts, or both. This is objectionable because it tends to intensify all variations in prices, to put a premium upon false statements, and to give the domestic producers the least protection when he needs it the most, viz., in a time of low prices. (2) By fixing an average price for the article and taxing it so as to bring the imported article up to that price. Under this arrangement the tax disappears when prices rise above the average, and increases in proportion as they fall below it. This was the method of the English Corn Law of 1815. It obviates most of the objections to *ad valorem* duties, but would require constant readjustment as the progress of methods of production lowered the cost. (3) To levy

the duty by number, weight, or bulk of the imported article, thus dispensing with invoices, oaths to their accuracy, and other encouragements to perjury. This is the method of the English tariff, but that of the United States attempts a most unhappy combination of this with the *ad valorem* method. (R. E. T.)

TASCHEREAU, ELZEAR ALEXANDER, cardinal and archbishop of Quebec, was born Feb. 17, 1820, at St. Marie de la Beauce, Quebec. He is of distinguished French origin, his father having been Jean Thomas Taschereau, Judge of the King's Bench, Quebec, while some of his ancestors held even more prominent positions. After studying at the Quebec and Grand Seminaries, he, in his seventeenth year, proceeded to Rome, where he received the tonsure. Returning to Quebec, he pursued his theological studies, and in 1842, though under canonical age, was ordained priest. Shortly after his ordination he was appointed to the chair of philosophy in the Grand Seminary, which post he occupied for twelve years. While holding this office he endeared himself to his co-religionists and many others by his voluntarily acting as nurse and spiritual comforter to the many Irish emigrants who, driven from their home by famine, had been taken down by malignant fever during the voyage and landed on Grosse Isle, in the St. Lawrence River, thirty miles below Quebec, which soon became a mass of loathsomeness and pestilence that gradually converted it into a cemetery. The heroic ecclesiastic was himself stricken down and narrowly escaped death. In 1851 he became professor of theology in the seminary, and in 1854 he again visited Rome, where he remained two years studying canon law, and received the title of Doctor of Canon Law. On his return to Quebec, he held in succession the offices of director of the Lower Seminary, of director of the Grand Seminary, of superior of the seminary and rector of Laval University, serving also as a member of the Council of Public Instruction for Lower Canada. On his return from a third visit to Rome, he was, in 1862, appointed vicar-general of the diocese of Quebec. In 1870 he revisited Rome as secretary to Archbishop Baillargeon, of Quebec, while attending the Vatican Council. On the archbishop's death in this year Doctor Taschereau was appointed conjunct administrator of the affairs of the arch-diocese, and in the spring of 1871 was consecrated archbishop. His visits to Rome have been frequent, and when last there, in 1887, he was presented with the cardinal's hat, being the first Canadian on whom this dignity has been conferred.

TATNALL, JOSIAH (1796-1871), Confederate naval officer, was born near Savannah, Ga., November, 1796. His father, bearing the same name (1762-1803), was then a U. S. Senator, and afterwards was a brigadier-general of militia and governor of Georgia. The son entered the navy as midshipman in 1812 and had some active service near Norfolk in the next year. He was with M. C. Perry on the African coast and with Porter in his expedition against West Indian pirates. During the Mexican war, in 1847, he took part in the attacks on Tampico and Vera Cruz. In 1856 he was flag-officer of the East Indian squadron, and on one occasion fired on Chinese who were repelling a British attack. When Georgia seceded he resigned his command and hastened to Savannah where he gathered a fleet of gun-boats to defend Port Royal, S. C., against Commodore Dupont's expedition. He had command of Norfolk in 1862 and when the Merrimac, altered into the iron-clad Virginia, was disabled in her famous fight with the monitor, Tatnall ordered her to be destroyed. During the rest of the war he had command at Savannah, and at its close went to Nova Scotia. He soon returned however and was made harbor-master. He died June 14, 1871.

TAUNTON, a city of Massachusetts, county-seat of Bristol co., is on Taunton River, 34 miles S. of Boston. It is at the junction of the Old Colony Railroad with other roads. It has a court-house, city-hall, 3 national banks, 2 savings banks, 20

churches, a high-school and several good schools, 1 daily and 2 weekly newspapers, and the State lunatic asylum. The industrial works comprise locomotive-works, copper-works, 10 foundries, cotton-mills, and factories producing nails, tacks, screws, jewelry, britannia ware, etc. There are also ship-yards and brick-yards. Taunton was settled in 1639 and became a city in 1864. Its population in 1880 was 21,213.

TAXATION. The United States furnish an excellent field for the study of the practical operation of methods of taxation, in p. 85 (p. 91 Am. Rep.). that there are in this country forty-eight separate governments besides that of the nation, which have the right to determine the methods in which they will levy upon the resources and the extent of the people for public purposes, only ten of them being in any way restricted by any superior authority in this respect. The legislation of the ten Territories, which are States in the making, is subject to the revision of Congress. The Legislatures of the thirty-eight States are limited only by the provisions of their own constitutions and of that of the United States. The national government is limited only by the latter.

The national government is the only one whose duties and resources are co-extensive with the nation. Before the Constitution of 1787 was adopted it had no powers of taxation, and could only assess the States to obtain money for its necessary expenses in conducting the wars and managing the diplomacy of the country. The proposal to extend to it the power to levy taxes on imports, as much for the sake of a general system of protection to home industry as to make its treasury independent of that of the States, was defeated by the negative vote of New York. This fortunate refusal precipitated negotiations for the formation of "a more perfect union," and the new Constitution conveyed to the national Congress "power to collect taxes, duties, imposts, and excises, to pay the debts and provide for the common defence and general welfare of the United States," and to "borrow money on the credit of the United States." But this large grant was accompanied by decided restrictions. The first is that "All duties, imposts, and excises shall be uniform throughout the United States." The second, that "No capitation or other direct tax shall be laid, unless in proportion to the census or enumeration" elsewhere provided for. The third, that "No tax or duty shall be laid on articles exported from any State. No preference shall be given, by any regulation of commerce or revenue, to the ports of one State over those of another." On the other hand it is provided that "No State shall, without the consent of the Congress, lay any imposts or duties on imports or exports except what may be absolutely necessary for executing its inspection laws; and the net produce of all duties and imposts laid by any State on imports or exports shall be for the use of the treasury of the United States; and all such laws shall be subject to the revision and control of Congress." The interpretations of the Supreme Court have determined (1) that Congress has no power to levy duties on exports under any circumstances; (2) that the restriction upon the power of direct taxation does not apply to an income tax, that being a form of direct tax which the authors of the Constitution could not have had in mind; (3) that no State may tax the "instrumentalities" which the Federal government deems proper to create or employ for carrying out its purposes, such as property in the debt of the United States.

The grant of power thus conveyed has proved much more extensive than its authors contemplated. In fact it has transferred to the national government all the popular and easy forms of taxation, as it possesses not only the sole right to levy import duties, but the sole power to collect excise duties also. The attempt of any State to collect revenue from the makers of any commodity would only result in the transfer of its manufacture to other States. At the same time the jealousy

of the States at the time of the adoption of the Constitution prevented any equally extensive transfer of the duties and responsibilities of government to the nation. Thus we have a national government possessing the most ample revenues, but in time of peace doing less for its people than any other national government of the civilized world. The costs of maintaining the national executive and his cabinet, Congress, the treasury, the comparatively insignificant army and navy, the post-offices, the system of Federal courts of extremely limited jurisdiction, and the tax-collecting machinery itself make up the necessary expenses of the national government. To these it voluntarily, and in the face of protest from the friends of States' rights, has added outlays for the construction of internal improvements, harbors, grants for education, and various minor expenditures. And in addition to its revenue from taxation, it long derived a revenue from the sale of lands on the public domain, and still counts that among its minor sources of income. Under the ordinary working of the Constitution there is a vexatious disproportion between constantly swelling revenue and restricted possibility of expenditure.

This anomaly did not at once appear after the adoption of the Constitution, nor for several years later, as the United States government was burdened by a considerable debt, incurred in the prosecution of the war for independence, and, through the influence of Alexander Hamilton, was induced to assume the war debts of the States. But as early as 1806 Pres. Jefferson announced to Congress the approach of a time when the revenue would be in excess of the constitutional wants of the government, although all the excise taxes enacted in Washington's administration had been repealed in 1801. As in his view it would be unwise to reduce the tariff in order to reduce the revenue, he proposed that the powers of Congress be enlarged by the amendment of the Constitution, so as to enable it to undertake a great system of internal improvements.

The outbreak of another war with Great Britain both postponed the appearance of a surplus of revenue and forced the re-enactment of the excise taxes. But in 1829 we find Gen. Jackson, in his first message to Congress, again announcing the approach of a surplus, and proposing that it be distributed among the State governments in proportion to population. After a futile attempt of the Whigs under Mr. Clay's leadership to distribute the specific revenue from the sale of lands, a law proposed by Mr. Calhoun was passed in 1836, and signed by Pres. Jackson, "deposing" with the States in quarterly instalments the surplus in the national treasury.

Before the third of the contemplated instalments had been made, the business depression of 1837, and the losses of government money through the failure of the State banks to which Pres. Jackson had transferred it, compelled the treasurer to stop payment. In this course he was sustained by Congress, which suspended the distribution law. In recent years the State of Virginia has sued for this fourth deposit, but was non-suited because the court upheld the validity of the suspending law. Of the three deposits made under the law of 1836, most of the States made wise and fruitful use. The common schools of many of them draw revenue from the fund to this day. But in some States there prevailed ideas of financial management now happily obsolete. Thus the State of New Hampshire divided it up among its citizens, while levying the usual taxes for the support of the State government.

In the interval between the panic of 1837 and the outbreak of the war there was no surplus, partly because of the war with Mexico and partly because of the bad financial management, which left a debt of \$61,140,496 on the country in 1860, some of it paying twelve per cent. interest. Of course the expenses of the war and the pressure of the debt prevented the

accumulation of a surplus in the twenty years that followed it, although the tariff for many years was full of duties for revenue as well as protective taxes, and the system of excise taxes was revived with a thoroughness never known before. But the refunding operations of the treasury having put a large part of the debt out of reach for redemption at par, by 1887 it was found that in spite of the repeal of most of the taxes imposed for a war revenue, and repeated reductions of the tariff and the repeal of all merely revenue duties it contained, that the income of the government was becoming much in excess of its legitimate outlays. This at once made the surplus a question of national politics. The free trade party proposed to retain the excise taxes on alcoholic liquors and tobacco (the only survivors of the general repeal), and to effect a reduction of the revenue by enlarging the free list of the tariff and by a very general reduction of duties on imports. The protectionists favored a reduction of duties only so far as it would not impair the protective character of the tariff, and proposed the repeal of the excise taxes on tobacco and on alcohol used in the arts, and even, if necessary, the entire abolition of excises, as in 1801. A third proposal is to return to the policy of 1836, leaving the issue between free trade and protection to be decided on its own merits, but giving to the States the surplus of revenue from such taxes as the national government believes it can collect without unduly burdening the people, whether these come from a revenue tariff or a tariff for protection to home industry, or from either of these, together with a system of excise taxes on articles whose use it is desirable to discourage. The advocates of this plan would connect with this distribution of the surplus conditions as to its expenditure, such as have accompanied grants of money and lands to the States for the promotion of education or the construction of railroads. They would require its use (1) for the promotion of education and the abolition of illiteracy; (2) the payment of State debts with accumulated interest, without regard to acts of repudiation passed by any State; (3) to the relief of the burdens of local and State taxation.

The problem devolved upon the States and their subordinate governments of collecting sufficient revenue for the cost of the multifarious duties they have to discharge has been solved in as many ways almost as there are States. An excellent summary of their methods will be found in Prof. Richard T. Ely's work on *Taxation in American States and Cities* (New York, 1887). It has been a favorite idea with our legislators that natural equity demanded the equal taxation of every kind of property, without regard to the likelihood of injuring the community by driving industries to localities more favored by the tax laws, and also without regard to the enjoyment of much greater favors from the community by some industries than by others. Equally indifferent have been the laws of many States to the practicability of collecting certain taxes; and bonds of foreign corporations held within the State and other equally intangible forms of personal property have been taxed on a par with real estate, thus offering a premium on the easy evasion of the laws. In this respect the tax-system of Pennsylvania has generally been regarded as superior to that of the States generally, which is due to the fact that in no State have the principles of economic and fiscal science had so many keen and practical students.

While it is in the highest degree desirable that the incidence of taxation should approximate to equality throughout the Union—a point most carefully guarded by the Constitution as regards the national taxes—this is the respect in which the differences have been most striking and harmful. Of course in the newer and poorer States of the Union the rate of taxation *per capita* must be much lower than in the older and wealthier commonwealths. But we find that even among these older States there are differences out of all proportion to the differing wealth of their people.

Thus in 1880 the tax-rate in Massachusetts was \$16.20 a head, but less than \$9 in Pennsylvania, for both the expenses of the State and those of its local and subordinate governments. The chief reason of this is found in the difficulty of raising an adequate revenue by direct taxation, which leads State and local governments to skimp the work of government, to be content with inadequate schools and wretched roads, and to regard "economy" as the one virtue in fiscal management. To this policy the New England States generally have been honorable exceptions, and Massachusetts especially so, but at serious cost to themselves. Many of the smaller industries, and those not especially favored by local circumstances, have been driven to the Middle States, where the tax-rate is lower because the State governments take a less exacting view of their duty to their people.

Taking the country as a whole, however, we find that the direct taxation upon all kinds of property and incomes is higher than in any country of Europe, except one, and an analysis of local tax-lists seems to show that nearly three-fourths of this burden is borne by people whose estates amount to less than \$5000 each, this class constituting ninety-seven per cent. of the taxpayers. The aggregate of property taxes levied by the State and local governments in 1880 was \$312,750,000, being \$6.23 a head of the population, and \$18.50 per \$1000 of its property.

Remedies for the weight of this great burden have been sought in (1) the monopoly of monopolies like the gas-supply and street-railways by municipal governments; (2) and in the heavier taxation of such monopolies as railroad corporations by the States, so as to secure from them some equivalent for the valuable franchises bestowed upon them by the community. But even these are only alleviations of an evil, which must be corrected in a more radical way, either by the transfer of costly government duties like education and police to the national government, or by the transfer of its surplus of revenue from the national government to the States.

The former proposal is that which commends itself to those who wish to see the general government strengthened at the expenso of the States, as has been the tendency throughout our history, with few interruptions. The latter should commend itself to those who value the State governments as a counterpoise to the centralizing tendency. As such it was advocated by Mr. Calhoun in 1836, and accepted by the States' Rights party of that day. The difficulty of securing a two-thirds vote in Congress and the vote of three-fourths of the State Legislatures for an amendment to the Constitution makes the former plan very difficult of application. It is safe to say that nothing but the prolonged failure to return to Mr. Calhoun's plan can give it a chance of adoption. It is that which may bring the country to such an urgent sense of the need of a fiscal reconstruction as may force the adoption of the most drastic remedy at hand. At present the proposal to aid the States in educating their illiterate population, and that for refunding the amount of the direct tax levied in 1861 as a war measure by the general government, both indicate a growing disposition to treat the national revenue as not to be isolated from the needs of the State and local governments. (R. E. T.)

TAXIDERMY (derived from the Greek *táxis*, arrangement, and *derma*, hide or skin) is the art of preserving the outward forms of birds and animals. The stuffing of birds and other animals is of ancient date, but the first to adopt the art as a business were the Verreaux Frères, of Paris, early in the present century. Examples of their work may be seen in the American Museum in Central Park, New York. Before their day each museum was obliged to collect its own specimens and have them stuffed as they could. At the present day many individuals and firms, both in Europe and America, make a special business of the art. The naturalists of former centuries made no

attempt to collect specimens as nearly as possible in a state of nature. Even Audubon paid no attention to taxidermy. When he secured a rare bird he pinned it to a tree and made drawings to reproduce, as nearly as possible, the natural tints of the plumage. After this the skin was removed and dried; but no attempt was made to stuff it so as to resemble the bird while alive. The collection of drawings left by Audubon have always been highly prized; but if, instead of the drawings, the great naturalist had acquired the art of taxidermy, his collection would have been more valuable. The noted English naturalist, Charles Waterton, was the first in his special line of investigation to practise taxidermy. His specimens, now in the American Museum in New York city, are of great value as attempting to show the natural positions of the birds. Waterton left particular directions as to the stuffing of birds. He pointed out that a bird's body is not completely covered by feathers, but has places about the shoulders, under the wings, and on the thighs, where the skin is nearly bare. Unskilful taxidermists stuff these parts to a fuller extent than in nature, with the result of destroying the original proportions. He also pointed out that, in mounting, the legs were usually too much lengthened, and advised that the three bones of the legs should be fixed to form the letter Z, because the upper joint of the thigh is never straight.

In the practical work of taxidermy, the skin of a bird demands the most careful attention from the moment it is killed. Cotton should be used to fill the wounds, and a damp sponge to wipe blood from the feathers. In cold weather the bird may be allowed to become cold before skinning; but in hot weather it must be skinned at once. The operation is this: beginning at the breast-bone, the skin is slowly separated by forcing a blunt instrument between it and the flesh; the bones of the wings are cut at the shoulder-joints, and when getting the skin from the skull the vertebrae can be unjointed; then remove the brains and eyes; the flesh is taken from under the bill, using care not to mutilate the openings of the ears or eye-lids; the skin should then be rubbed with a solution of arsenic or corrosive sublimate and prepared for drying.

Dr. Jared P. Kirtland, of Ohio, one of the best taxidermists in the United States, but more especially in the West, gave the following instructions to young taxidermists. The implements needed are: a glover's three-cornered needle, a knitting-needle sharpened and fixed in a handle, and a sharp knife. Arsenical soap is to be prepared as follows: pulverized arsenic, 2 lbs.; potash in powder, 12 oz.; camphor gum, 5 oz.; white soap, 2 lbs.; lime in powder, 4 oz. Shave the soap into small pieces, place it in a pipkin over a slow fire and add a little water; stir with a wooden spatula till the soap is dissolved; take it off and add potash, and stir well; add the lime by small quantities and then the arsenic, stirring till all are thoroughly mixed; when nearly cold add the camphor, dissolved in strong alcohol; if the mixture becomes too thick, add water sufficient to reduce. Dr. Kirtland advised that the bird be allowed to lie from 2 to 4 hours before skinning, without regard to the temperature of the day. In handling the damp skin care should be taken not to squeeze the head. The throat should be swabbed with cotton and filled with powdered plaster of Paris. Cotton should also be crowded into the mouth, and plaster into all the cavities of the head. The cotton and plaster prevent fluids from issuing out of the head and spoiling the skin. Having smoothed the feathers carefully with cotton, lay the bird upon a piece of thick pasteboard or a thin board covered with cotton-flannel, soft side up. Place the bird upon this with the head toward the left hand. Separate the legs and feathers and at the end of the breast-bone begin to cut through the skin, downwards. If blood or other fluids issue, put in plaster of Paris to absorb them. Do the left side in the same manner, cutting the muscles and the flesh from the body. Cut the muscles of the wings. The

membrane of the ear must be undermined by a knife and the knife forced upwards, bringing out the ends nearest the bill. Remove the eyes. Clear away the brain, tongue, and muscles. Wash the inside of the skull with arsenical soap and fill the skull full of powdered arsenic. Then press a piece of cotton into the sockets. Leave the bones of the wing and cut the muscles. Insert a thread at the other end of the bone in the skin; break the knob off at the end of the wing-bone. Take the muscles out of the legs and sometimes take the fat off the legs. Lubricate with arsenical soap and wind the bone with cotton. Then tie the wings with threads, not too tightly. Lubricate the whole with arsenical soap. Get the ball of cotton out of the nostrils. Run a little awl, of the size of a small wire, behind the toes to the joint; then straighten the legs and tie the bone to the wire. Take the cotton off and put more on with arsenical soap. Prepare a cork body of the length of the bird and as large round as a large-sized bottle-cork. Join the two wires which are already in the legs, and another for the neck to the cork body, leaving them to project 3 or 4 ins. outside the real body. Wind cotton upon the wire till it becomes as large as the neck, and lubricate with arsenical soap. Wind cotton around an instrument like a knitting-needle till it is about the size of the little finger and take them off—as fast as made—and lay them on, under, and around the cork body. Press it from time to time and put in arsenic powder. Insert the leg wires; do not place the legs too far back or make the breast too full. Use arsenic freely. Begin at the upper part to sew. Put a little *aqua ammoniac* in the eye-sockets and let it remain for an hour. Then clear away unnecessary matter and put putty in the cavities. Imbed a glass eye in the putty, taking care not to let the putty show. (F. G. M.)

TAYLOR, GEORGE (1716-1781), a signer of the Declaration of Independence, was born in Ireland, and emigrated to Pennsylvania as a "redemptioner" in 1736. From being a laborer in an iron-foundry he rose to be a proprietor in Northumberland co., and in 1764 was elected to the colonial assembly. After 5 years' service he was made county judge, and in 1775 was again a member of the assembly. Here he took the patriotic side, and on July 20, 1776, was one of the new members chosen as delegates to Congress. As such he was allowed to affix his signature to the famous Declaration on Aug. 2. He was afterwards employed in negotiating treaties with Indian tribes. His service in Congress was brief, and he died at Easton, Pa., Feb. 23, 1781.

TAYLOR, NATHANIEL WILLIAM (1786-1858), theologian, was born at New Milford, Conn., June 23, 1786. He graduated at Yale College in 1807, studied theology, and in 1812 was ordained pastor of the First Congregational Church of New Haven. In 1823 he was made Dwight professor of didactic theology in the seminary then established in connection with Yale College. During his 36 years of service in this position about 700 students received his instruction. His essays and sermons attracted marked attention. He carried further Dwight and Edwards' modification of Calvinistic theology, and in his *Works* insisted that man, though by nature indisposed to holiness, was yet not without ability to repent. This view he maintained not only in his lectures on the "Moral Government of God," but also in the *Christian Spectator*, which he edited for twenty years. In it he also vigorously opposed Unitarianism. He died March 10, 1858. Rev. Dr. Noah Porter, his son-in-law, edited his *Works* (5 vols., 1858-62).

TAYLOR, WILLIAM MACKERGO, minister, was born at Kilmarnock, Scotland, Oct. 23, 1829. He graduated at the University of Glasgow in 1849 and studied theology at Edinburgh. He was ordained pastor of a United Presbyterian church at Kilmaurs, Scotland, in 1853, and in 1855 accepted a call to a church in Liverpool. In 1872 he became pastor of

the Broadway Tabernacle Church, New York. He has twice delivered courses of lecture on "Preaching" in Yale Seminary and another course on "Gospel Miracles" at Princeton. From 1876 to 1880 he was editor of the *Christian at Work*. Many volumes of his sermons have been published, among them being *The Lost Found* (1870); *David, King of Israel* (1875); *Elijah the Prophet* (1876); *Songs in the Night* (1877); *Peter the Apostle* (1877); *Daniel the Beloved* (1878); *Moses the Lawgiver* (1879); *Paul the Missionary* (1882); *Joseph the Prime Minister* (1886). He has also published a biography of *John Knox* (1885).

TECUMSEH (1770-1813), noted Indian chief, was born near the site of Springfield, Ohio, about 1770. In youth he was of a mild disposition, yet was always averse to the whites. In his first fight with them, when 20 years old, he is said to have run away, yet he afterwards had a reputation for dauntless courage. In 1804, with his brother, Elskwatawa, known as the "Prophet," he formed a scheme for uniting the Indian tribes and extirpating the whites. They visited the tribes on the great lakes and the Mississippi, professing to deliver a message from the Great Spirit. At their camp, near Greenville, some hundreds of warriors were gathered, and in 1810 Gov. W. H. Harrison was notified that the further appropriation of lands by the whites would be resisted. In the autumn of 1811 Tecumseh, in furtherance of their project, went to visit the Creeks and Cherokees in Alabama and Georgia. During his absence Harrison, with a force of 900 men, marched to Tippecanoe and encamped there. The Prophet directed an assault to be made early on Nov. 7, but the Indians were repulsed and fled. Tecumseh in the next year went to Canada, then threatened with invasion by Gen. Hull's army. With 700 men he joined the British forces, fought at the River Malden, and was present at Hull's surrender at Detroit. He was commissioned brigadier-general with command of all the Indians fighting for the king. During the contest in the next year he appears to have lost heart in the British cause, and before the battle of the Thames, Oct. 5, 1813, he is said to have predicted his own death. He had command of the right wing, which was routed by Col. R. M. Johnson, who is said by some to have shot Tecumseh. His brother, the Prophet, a man of low cunning and altogether inferior character, lived to obtain a pension from the British, but lost his reputation, and died in 1834. See the *Life of Tecumseh* (1878) by E. Eggleston and L. E. Seeley.

TEETH. See DENTISTRY.

TELEGRAPH. This article is confined to the history of the telegraph in the United States. About the year 1827 Prof. p. 112 (p. 119 Joseph Henry (afterwards secretary of the Smithsonian Institution) began a series of experiments in the attic of the Boys' Academy building in Albany, N. Y., among which was included the running of a wire about the room, and the sending of signals from one end to the other by means of an electric current. During the summer of 1832 Prof. S. F. B. Morse (for whom see *ENCYCLOPEDIA BRITANICA*) conceived the idea of an electric or electro-magnetic telegraph; and, after numerous experiments, announced his invention to the public in April, 1837. Hon. Levi Woodbury, secretary of the U. S. Treasury, on March 10, 1837, issued a circular requesting information in regard to establishing a system of telegraphs for the United States, to which Prof. Morse replied, giving an account of his invention, its proposed advantages and probable expense. At that time he presumed 5 words could be transmitted in a minute. Morse petitioned Congress for aid to enable him to test the practical operation of his invention, and an appropriation of \$30,000 was made for this purpose. In 1843 he began to erect the first telegraphic line between Washington and Baltimore, a length of 40 miles. It was at first proposed to lay the wires in leaden pipes along the line of the Baltimore and Ohio

Railroad, but this plan was abandoned, and the wires were suspended on poles, a metallic circuit being formed. The wire had reached Annapolis Junction just before the National Whig convention opened in Baltimore in May, 1844. A friendly Congressman suggested to Prof. Morse that the opportunity had now come for him to show what could be done. A man at Annapolis Junction was directed to get information of what the convention had done as soon as the afternoon train arrived there from Baltimore, and telegraph it at once to Washington. The capital was in a ferment, every citizen being anxious for the news from Baltimore, which should be brought by railroad. Prof. Morse and his friend spent that afternoon in his machine-shop. The wire was operating well, and soon Morse was able to announce, "The convention has adjourned. The train for Washington has just left, and the ticket is Clay and Frelinghuysen." In spite of some doubts the news was quickly spread in Washington before the train bearing the delegates from the convention could reach that city. This fact should have settled the question that Morse's invention was of practical use. And yet almost a year passed before the Washington office could be opened for regular business. The earnings of its first week, in April, 1845, were only \$3.09.

The telegraph line from Washington was but slowly extended to Philadelphia and New York, a distance of 250 miles. It reached Boston in 1845, and became the great line of the North, from which branched two others, one from Philadelphia to Pittsburg, Cincinnati, and St. Louis, 1000 miles; the other from New York to Albany, Buffalo, Cleveland, Chicago, and Milwaukee, 1300 miles. Another line, 1395 miles in length, connected Buffalo, Niagara, Toronto, Montreal, Quebec, and Halifax. Two lines ran south to New Orleans, one from New York, Washington, and Charleston, 1966 miles; the other from Cleveland and Cincinnati, via Nashville, 1200 miles. The only line constructed with government aid was the original one connecting the cities of Washington and Baltimore. The others were established by private enterprise. The following table exhibits the annual receipts of the "Magnetic Telegraph Company," extending from Washington to New York, which was the first organized in this country: From Jan. 27, 1846, to July 1, 1846, \$4228.77; to July 1, 1847, \$32,810.28; to July 1, 1848, \$52,252.81; to July 1, 1849, \$63,367.62; to July 1, 1850, \$61,383.98; to July 1, 1851, \$67,737.12; to July 1, 1852, \$103,860.84; total amount received up to July, 1852, \$385,641.42. In 1852 the telegraphic charges from Washington to various cities were as follows: Baltimore, 20 cents; Boston, 75 cents; Buffalo, 90 cents; Chicago, \$1.25; Cincinnati, 70 cents; Louisville, 95 cents; Milwaukee, \$1.35; Nashville, \$1.35; New Orleans, \$2.20; New York, 50 cents; Philadelphia, 30 cents; Pittsburg, 45 cents; Portland, Me., 95 cents; St. Louis, \$1.20.

A report made for the U. S. census of 1850 stated: "The amount of business which a well-conducted office can perform is immense. Nearly 700 messages, exclusive of those for the press, were sent in one day over the Morse Albany line; and a few days after the Bain line at Boston sent and received 500 communications. Another office, with two wires, after spending three hours in the transmission of public news, telegraphed in a single day 450 private messages, averaging 25 words each, besides the address, 60 of which were sent in succession without a word of repetition. Messages passing from one very distant point to another have usually to be rewritten at intermediate stations; though, by an improved method, the Seaboard line has, in good weather, transmitted communications direct between New York and Mobile, a distance of nearly 1800 miles without intermediate rewriting. By the Cincinnati route to New Orleans, a distance of nearly 2000 miles, the news brought by an Atlantic steamer at 8 A. M. has been telegraphed from New

York to that distant point, and the effects produced in the market there returned to New York by 11 A. M. The Congressional reports from Washington are usually received simultaneously in Baltimore, Philadelphia, and New York; and all that is necessary at the intermediate stations is for an operator to be present and receive the message as it is developed on paper by the instruments.

"The electric telegraph has been applied in this country to a new and highly important purpose—that of the registration of astronomical observations; thus establishing the best possible means for the determination of the difference of longitude. The observatories in different parts of the country are connected by telegraphic wires; and the most delicate experiments, dependent upon the appreciation of minute portions of time, have been successfully performed. This method has been recently used for the determination of the wave time of electrical currents.

"The great extent of the telegraphic business and its importance to the community is shown by a statement of the amount paid for despatches by the Associated Press of New York, composed of the seven principal morning papers—the *Courier and Enquirer*, *Tribune*, *Herald*, *Journal of Commerce*, *Sun*, *Times*, and *Express*. During the year ending Nov. 1, 1852, these papers paid nearly \$15,000 for despatches, and about \$14,000 for special and exclusive messages not included in the expense of the association."

The original invention of Prof. Morse was what is known as the "single circuit." Soon afterward a needle system was invented containing two multipliers, and using an alphabet wherein the signals were dashes at angles instead of the Morse arrangement in parallel lines.

Alexander Bain, (q. v.) a native of Scotland, patented an electro-chemical telegraph on Dec. 12, 1846; and another patent was granted to him in connection with Robert Smith, in October, 1849. The advantages which the inventor attributed to the electro-chemical telegraph were: "1st. More economy and simplicity in the primitive construction; 2d. More rapidity in the transmission of despatches. A single wire, with a good insulator, can transmit 1200 letters a minute; 3d. An electric current, more feeble than ordinary, suffices to cause the apparatus to work; 4th. More simplicity and economy in the correspondence and superintendence; 5th. Fewer chances of error in the despatches sent." The Bain telegraph was materially improved by Henry J. Rogers. The earlier Bain telegraph lines ran from New York to Boston, from Boston to Burlington and Ogdensburg, from Boston to Portland, from Troy to Saratoga, and from New York to Buffalo.

The "House printing telegraph" was invented by Royal E. House, a Pennsylvanian, and patented April 18, 1846. The first line operating with this instrument was completed in August, 1850, by the Boston and New York Telegraph Company between those cities. It was patented in England by Jacob Brett. The difference between Morse's and House's telegraph was, principally, that the former traced at the distant end what was marked at the other; while House's did not trace at either end, but made a signal of a letter at the distant end which had been made at the other, and thus, by new machinery and a new power of air and axial magnetism, was enabled to print the signal letter at the last end at the rate of sixty or seventy strokes, or breaks, in a second, and at once recorded the information, by its own machinery, in printed letters. Morse's was less complicated and more easily understood, while House's was very difficult to be comprehended in its operations in detail, and worked with the addition of two more powers, one air and the other called axial magnetism. One was a tracing or writing telegraph; the other, a signal and printing telegraph. The earlier House lines were from Boston to New York, from Boston to Spring-

field, Albany, and New York, from Poughkeepsie to Troy, Albany, and Buffalo, and from Philadelphia to New York. In 1848 the House Printing Telegraph Company entered into competition with the Bain and a similar company. In 1849 the owners of the Morse patent sued the Bain operators, and a compromise was concluded by which the Morse patents were used over the wires of both companies. The Bain wires, however, were used between Boston and Montreal for many years. The House printing machine was in use until 1847. It was similar to the ticker of to-day, but larger; the operator turned a crank with his foot to induce the proper current. The House machine was much more rapid and could do more work than the Morse instrument, but in wet weather it became useless on account of the escape, and the wire had to be thrown upon the Morse apparatus. The House circuit was the best and the largest wire, being No. 6 gauge of plain iron. The insulators were made of a large iron cap which went on top of the pole. The wire rested in a cleat made of iron but insulated from the main cap, which was considered the best insulation at that time. In 1855 the Hughes printing machine was patented; but it was such a delicate instrument, with its vibrating spring, that it did not meet with much favor.

In 1855 the rival lines in the West had all been consolidated into one company, which was named the Ohio and Mississippi Printing Telegraph Company. The word "printing" was added on account of the company's using the House instrument. This company was incorporated in 1851 by the State of New York, with a capital of \$360,000, of which about \$75,000 was paid. At that time this company was only one of some twenty or thirty that were struggling for existence in the country, most of them situated in the Western States. Each company had a separate set of officers and employes of all grades; and instead of making money for its shareholders it was heavily mortgaged and working at a loss. The stocks of these companies were almost valueless, and the investors in the new company determined to buy them up and consolidate the management. By an act of the New York Legislature, April, 1856, it had its name changed to the Western Union Telegraph Company. The Legislature of Wisconsin also issued articles of incorporation of the company in 1856, when its capital was placed at \$500,000 with the privilege of increasing it to \$1,000,000. The company then turned its attention to the purchase and leasing of lines of struggling Western companies. It soon acquired control of all the wires west of Buffalo and Pittsburg. The wires east of those points were under the management of the American Telegraph Company, of New York, with Amos Kendall, president, though the Western Union built a new line from Philadelphia to Pittsburg.

In 1859 the telegraph line from Omaha to Salt Lake City to meet the California State Telegraph Company was projected and J. H. Wade, of Cleveland; Edward M. Creighton, of Omaha; J. M. Stebbins, of St. Louis; Hiram Sibley, of Rochester, N. Y., and others were the prime movers in this enterprise. The Indians interfered in every way possible by killing the line-men and cutting down the poles and wire after the gangs and troops had passed on. Down to 1860 the intervention of the government had been confined to the passage of a few acts granting aid and protection to parties proposing to extend the telegraph to the Pacific coast and to the Atlantic Cable Company. In June of that year Congress offered a bonus of \$40,000 a year for 10 years, in addition to rights on the public lands, to parties who would undertake the construction of a line from the Missouri to the Pacific; and the line was completed in 1861. The wire was seldom working more than two or three days at a time; after an interval of the same length the company would succeed in getting it to work for as many days more. But business was accepted at gold

rates and held at Omaha, because the time, even at this slow rate, was much shorter than the water route, via Panama. When the Indians ceased their opposition, the Overland Telegraph Company became a very fortunate venture.

At the beginning of the civil war the telegraphic territory of the country, was divided mainly between the American Company running through the eastern slope from Nova Scotia to New Orleans; the Southwestern, extending from New Orleans through Mississippi, Tennessee, and Kentucky to Louisville, and the Western Union Company, extending through the Middle and Western States. The California State Telegraph Company operated the lines on the Pacific slope connected with the Western Union by the line above mentioned; the Illinois and Mississippi Company operated lines west of Chicago; the Northwestern Company, those through Wisconsin and Minnesota, which maintained an independent organization until their absorption in 1884. These lines all worked in connection as one system, although under different managements. The capital stock of the Western Union Company was \$3,000,000, representing the \$2,000,000, to which it had been quadrupled, and accretions from various sources. In 1861 a stock dividend of \$3,000,000 was added. In 1863 and 1864 \$5,000,000 more was issued to represent extensions and new lines; and, in the latter year, the stock was doubled by an issue of \$11,000,000 as a dividend. In 1863 and 1864 the Russian extension was organized with a capital of \$10,000,000. During and after the civil war an active opposition arose from the United States Telegraph Company, competing in the territory of the Western Union over some 14,000 miles of wire. In 1866 commenced a plan of consolidation; the 14,000 miles of the United States Telegraph Company's wires were purchased with new stock of the Western Union valued at \$6,345,800. The Illinois and Mississippi and the Southwestern Companies' lines were absorbed. Bonds to the amount of \$1,652,000 were issued for the California Telegraph lines, and for each share of the American Company's stock three shares were issued. When this consolidation was accomplished, the Western Union Company stood without an important rival in the telegraph business of the country, with a capital stock of \$11,000,000 and a total nominal investment of \$47,877,350.

The year 1866 thus marked an important epoch in the history of the telegraph system in this country. From that time the stock of the Western Union Company was increased from \$41,000,000 to \$80,000,000 in 1884. In that year the National Telegraph lines were sold to the Baltimore and Ohio Telegraph Company, and the latter became a great rival of the Western Union. The National Telegraph Company was the result of a consolidation between the two telegraph lines running from Buffalo to Chicago along the "Nickel-Plate" Railroad, and from New York city to Buffalo along the West Shore Railroad. This made a continuous line from New York to Chicago. The consolidation extended the line of the Baltimore and Ohio from New York city to the principal cities east of the Mis-

issippi. The Baltimore and Ohio Telegraph, as a distinct organization, dated from Jan. 1, 1882, although the telegraph lines of the railroad were in operation many years before. During the civil war the railroad, in connection with the American Telegraph Company, made additions to its telegraph lines in order to transmit commercial messages. When the consolidation of the Western Union and the American lines took place the Baltimore and Ohio refused to surrender the independence of its telegraph system. On Jan. 1, 1877, the Baltimore and Ohio Telegraph broke away from the Western Union and gave assistance to the Atlantic and Pacific Telegraph Company. When, in the fall of 1877, the Western Union absorbed that company the Baltimore and Ohio sought other telegraph connections, which were secured in May, 1879, through the American Union Company. When the consolidation of the latter with the Western Union took place, in 1881, the Baltimore and Ohio determined to establish its telegraph system on a thoroughly independent basis, and the Baltimore and Ohio Telegraph Company was formed, and it soon determined to extend its lines to all important points east of the Rocky Mountains. But in 1887 the Western Union gained complete control of the Baltimore and Ohio Company, and since that time it has had practically no opposition. The special gain by the transfer was the acquiring of many miles of wires that ran along railroads, but had been used hitherto chiefly to help the service of such roads. In October, 1888, the Western Union Telegraph Company reported its outstanding capital stock at \$86,199,852.06, of which \$25,976,700 belongs to the company. The stock was increased during the year by the purchase of the Baltimore and Ohio Telegraph Company, for which purpose \$5,000,000 of additional stock was issued. The bonded debt, less balance in the sinking fund, was \$6,737,038.32. The gross revenues for the year ending June 30, 1888, were \$19,711,164.12, and the expenses were \$14,640,592.18, leaving a profit of \$5,070,571.94. The surplus amounts to \$7,498,548.94. In addition to the Baltimore and Ohio system, consisting of 6711 miles of line, carrying 54,087 miles of wire, and the New York and Southern system, consisting of 1528 miles of line, and carrying 5090 miles of wire, acquired during the year, the company constructed 6322 miles of new line, carrying 32,430 miles of wire, on which account there was appropriated \$1,219,590.67. The total additions to the plant were 14,561 miles of line, and 91,607 miles of wire, and 1583 additional and newly equipped offices. The average amount received per message during the year was 31.2 cents as against 30.4 cents the year before. At the close of 1888 the company owned and operated 171,375 miles of poles and cables, carrying 616,248 miles of wire, over which there were sent during the year 51,463,955 messages from 17,241 offices. In the 22 years of its existence the company earned and collected \$91,383,726.83, and paid in dividends \$51,185,565.07. The following table shows the growth of the Western Union Telegraph Company in various years since 1866:

Statistics of the Western Union Telegraph Company.

Year.	Miles of line.	Miles of wire.	Offices.	Messages sent.	Receipts.	Expenses.	Profits.	Average tolls per message. cts.	Average cost per message. cts.	Average profit per message. cts.
1866	37,380	75,686	2,250		\$6,568,925	\$3,944,006	\$2,624,920			
1870	54,109	112,191	3,972	9,157,646	7,637,449	5,104,787	2,532,662	69.5	45.7	23.8
1875	72,833	179,496	6,565	17,153,710	10,034,986	6,635,474	3,399,510	50.9	33.5	17.4
1880	85,645	233,534	9,077	29,216,509	12,782,895	6,948,957	5,833,938	43.7	23.7	19.3
1885	147,500	462,283	14,184	42,096,583	17,706,854	12,005,909	5,700,924	32.1	24.9	7.2
1886	151,832	489,607	15,142	43,289,807	16,298,638	12,378,783	3,999,855	37.6	28.5	9.1
1887	156,814	524,641	15,658	47,394,530	17,191,910	13,154,029	4,037,281	30.4	27.7	8.5
1888	171,375	616,248	17,241	51,463,955	19,711,164	14,640,592	5,070,571	31.3		

The fact that the Western Union Company had secured virtual control of the telegraph business in this country led to attempts in Congress from 1882 to 1885 for the establishment of a postal telegraph to be carried on by the U. S. government. (See POSTAL SERVICE.)

What is called quadruplex telegraph (or the transmission of 4 messages from a single wire at the same time) has been made possible by a combination of single and double currents. In the duplex working one operator sends upon a key which reverses and operates only on the sending battery, whilst the working of another key brings into play the full strength of the battery. At the receiving end one man reads his messages from a delicately adjusted instrument, which is acted upon only by the reverse currents of the first sending operator, while another receives his message from a less delicate machine, responding only to the stronger signals sent by the second sending clerk. To accomplish quadruplex working an arrangement is made, permitting transmissions in opposite directions at the same time. This is done by making the receiving apparatus of the home station insensible to the effects of the outgoing currents.

Later improvements of transmission include an invention which can send some hundreds of words per minute, and have them received at the receiving station in Roman letters, all ready for the attendant to place in envelopes and send to the persons addressed. Experiments are still making in regard to the laying of wires underground, and several miles of subways have already been laid in the city of New York with moderate success. The same experiments are extending to Washington, Boston, and other cities.

The aggregate mileage of telegraph lines in the United States used for public business exceeds 180,000; which is exclusive of railroad, government, private, and telephone lines, the length of which cannot be ascertained.

Submarine Telegraphs.—In June, 1852, the submarine telegraph between Dover and Ostend was completed, and on Nov. 1 electric communication was established direct between Great Britain and the continent of Europe. The history of the Atlantic cable is full of interest. Cyrus W. Field, of New York city, was applied to in 1854 for aid in completing a land telegraphic line which had been begun in Newfoundland, to cross the island, 400 miles, from Cape Ray to St. John's, from which it was intended to run a line of fast steamers to the west coast of Ireland, and thus bring America within a week of Europe. While studying this subject, and turning over the globe in his library, he thought, "Why not carry the line across the ocean?" Going to St. John's, Newfoundland, in March, 1854, he obtained from the Legislature of that colony a charter granting an exclusive right for 50 years to establish a telegraph from the continent of America to Newfoundland and thence to Europe. On March 10, 1854, the articles of association were signed by five citizens of New York—Peter Cooper, Moses Taylor, Marshall O. Roberts, Chandler White, and Cyrus W. Field. Mr. Cooper became president of the association. Mr. White subsequently died, and Wilson G. Hunt took his place. The association was called "The New York, Newfoundland, and London Telegraph Company." More than two years were required to build the land line across Newfoundland and Cape Breton Island. Meantime Mr. Field went to Europe and ordered a submarine cable, to connect Cape Ray and Cape Breton. This was sent out in 1855, and was lost in a gale in an attempt to lay it across the Gulf of St. Lawrence, but the attempt was successfully renewed in 1856. In that year Mr. Field again went to London and organized the Atlantic Telegraph Company, to carry the line across the ocean. As an evidence of his confidence in its success, Mr. Field subscribed a fourth of the entire capital stock of the company. He secured from the British and American governments aid

in ships, and he accompanied the expeditions which sailed from England in 1857 and 1858 for the purpose of laying the cable across the Atlantic Ocean. Twice the attempt failed in 1857, and again in 1858. The third attempt proved successful, and in 1858 telegraphic communication was established between England and America. The first public messages were congratulations between Queen Victoria and Pres. Buchanan, which occupied in transmission 67 minutes each. Doubts were expressed of the genuineness of these despatches, and only when a despatch conveying the action of Parliament on an important public matter was verified by mail two weeks afterward were these despatches accepted as real. But in a few weeks the cable ceased to work, and it was again pronounced a failure. Mr. Field, however, never lost faith in its ultimate success, and he made frequent trips to Europe to resuscitate the company. But the American civil war broke out, and not until 1865 was another expedition prepared.

Meantime submarine telegraphy had been greatly improved in many ways, a better cable was prepared, and the steamship *Great Eastern* took it on board and sailed for the American coast. Over 1200 miles of cable had been laid, when, by a sudden lurch of the vessel, the cable snapped and was lost. The bottom of the sea was dragged for days in search of the broken end, and the expedition returned to England. In 1866 the *Great Eastern* again sailed with a fresh cable, and 2000 miles of wire were safely stretched across the ocean, and the communication was perfected July 27, 1866. After landing this the *Great Eastern* returned to the middle of the ocean, and after two months' search succeeded in grappling the sunken cable of the year previous. It was brought up from a depth of two miles, joined to the cable on the steamship, and carried safely to the western shore. After twelve years of incessant labor, in which he crossed the ocean nearly fifty times, Mr. Field saw the crowning effort of his life accomplished. Congress voted him a gold medal with the thanks of the nation, while the prime minister of England declared that it was only the fact that he was a citizen of another country that prevented his receiving high honors from the British government. The first cable cost \$1,256,250, and the company's expenditures up to Dec. 1, 1858, amounted to \$1,834,500. Among the despatches sent over the new cable was the speech of the King of Prussia just before the Austrian war of 1866. It cost \$3000 to transmit it. This cable has been in running order almost continually since its successful completion.

In 1874 work was begun by the "Direct Cable Company" to lay a cable between Ballinacallig Bay, in the southern part of Ireland, and Rye, New Hampshire, by way of Nova Scotia. It was finally completed in 1875. The Commercial Company laid a series of duplicate cables in 1884. The starting point may be considered the village of Waterville, near Ballinacallig Point, but a few miles south of Valentia, the terminus of the earliest ocean line. From this point the new line has double connections to the English and European centres; a land line direct to Liverpool, London, and Paris; also a submarine cable through the English Channel to Havre, thence two separate cables across the Atlantic to Canso, from which place it has two submarine cables to the United States, one to Rockport and another direct from Canso to New York city, thus giving double lines from London and Paris to Boston and New York. These lines are all duplicated for two reasons, the press of business and the contingency of disaster to one of them. The system adopted is known as octoplex harmonic, one wire doing the duty of eight. The cost of these cables is estimated to have been about \$10,000,000.

Method of Working.—In the early part of the history of the Atlantic cable, the flash system of signals was used; the messages were spelled out by flashing rays of light back and forth across a standard line, the right

and left flashes corresponding with the dots and dashes of the ordinary telegraph alphabet. In Stern's system, which is now used by the French cable, having its terminus at North Eastham, Mass., the light is flashed by reflection from an extremely light mirror, which is turned to right and left by the opposing influence of positive and negative impulses. This system has the advantage of being operated with very slight impulses, but also the disadvantage of leaving no permanent record. To secure the latter very important end, the recording instrument has been adopted. The recorder is a horseshoe magnet, electrified by the usual circle of fine wire, and attracting a small metallic coil. The coil is hung between the magnet-poles; and by a light lever and a thread almost as fine as the strand of a cobweb it is connected with a delicate siphon hung in a little reservoir of ink. The ink is electrified, so as to produce a repulsion of the particles, making it flow more readily through the siphon, which outside is about the size of a darning-needle, and the interior tube scarcely larger than a hair. The lower end of the siphon rests against a paper tape playing perpendicularly through rollers. The whole machine is almost of gossamer fineness and flexibility, so as to minimize the electric strain necessary for working the cable. The Commercial (or Mackay-Bennett) Company has adopted the system known as the William Thomson siphon recorder. Between the two poles of a powerful magnet is suspended a piece of soft iron. In this the magnetism is concentrated. In the field is suspended a coil of fine wire. The motion of the coil is transmitted to the siphon—fed with the purest aniline ink—by means of a silk fibre so fine as to be almost invisible. A revolving electric motor feeds the ink generator by induction between its armatures and two enveloping shields, and that induces the current. The instrument used in Wall street, New York, is very small and the work noiseless. An endless tape passes under the point of the siphon, which moves back and forth at the rate of 100 dots a second. The tape can be read at any time, and the messages preserved; but this could not be done by the old system of mirrors.

It has been proposed to establish telegraphic communication between Australia, New Zealand, Canada, and Great Britain, by means of a line perfectly independent of existing lines and freed from foreign influences. This would require a chain of cables across the Pacific Ocean from Brisbane or Sidney to the north of New Zealand, thence via the Fiji Islands, the Fanning Islands, the Sandwich Islands to Vancouver Island, then across to the new city of Vancouver on the mainland, the terminus of the Canadian Pacific Railway. The line would follow this railway and be extended possibly to Gaspé, in the Province of Quebec. From Gaspé a new cable would be laid through the Straits of Belle Isle to the United Kingdom, unless it was found to be practicable to secure control of the existing lines across the Atlantic. The total length of cables contemplated in the Pacific and Atlantic Oceans is 11,145 miles, and the distance across the continent will be 3450 miles, making in all about 15,000 miles.

Since the opening of the first Atlantic cable the rates charged for the messages have been steadily reduced, as is shown by the following: In 1866, \$100 were charged for 20 words or less; from November, 1867, \$50 for 20 words or less; from December, 1867, \$25 for 10 words or less; from September, 1868, \$16.85 for 10 words or less; from June, 1869, \$10 for 10 words or less; from August, 1869, \$7.50 for 10 words or less; from December, 1870, \$15 for 10 words or less; from July, 1871, \$10 for 10 words or less; from May, 1872, \$1 per word; from May, 1875, 50 cents per word; from December, 1884, 40 cents per word. (F. G. M.)

TELESCOPES, AMERICAN. The earliest manufacturer of astronomical telescopes in the United States of whom we have record was Amasa Holcomb, of Southwick, Mass. He made his first experiments in grinding lenses in 1826, and completed in 1830 an

achromatic objective of about 48 inches focal length.

See Vol. XXIII. Owing, however, to the difficulty of obtaining suitable glass for objectives, he turned his attention to the manufacture of reflecting telescopes, and

achieved considerable success in this direction. His reflectors were from 4 to 10 inches in diameter, mounted in the Herschelian form; that is, with the mirror inclined slightly to the axis of the telescope, so that the image is formed near the upper edge of the tube, and is there magnified and examined. In 1838 Mason, Smith, and Bradley, the two first, at that time, students in Yale College, built a reflector of 12 inches aperture, with which some very creditable work upon nebulae was accomplished.

Thirty years ago the most prominent telescope-maker in the United States was Mr. Henry Fitz, of New York. His largest objectives are given in the table below. Spencer, of Canastota, N. Y., made in 1856 the 13½-in. refractor of the Litchfield Observatory of Hamilton College, with which Dr. Peters has discovered no less than 47 asteroids, and Davis, of Cincinnati, an 11-in. objective which is now mounted at Smith College, Northampton, Mass. Many small objectives, some of a very high order of excellence, have been produced by American opticians—Stendicke, Kahler, Gregg, Allen, Walther, Byrne, Clacey, and Tolles, the three last-named making especial efforts to grind lenses of short focus. Clacey's largest glass, of 10½ in. aperture and 9 ft. 9 in. focal length, has recently been completed for the Smith Observatory, Geneva, N. Y. The ratio of aperture to focal length is here 1 to 12, while the usually accepted ratio is about 1 to 15.

Reflecting telescopes have thus far met with comparatively little favor in this country. The only one of large size (28 in.) was made by Dr. Henry Draper in 1866-70, and used by him at his observatory at Hastings-on-the-Hudson in researches in spectrum photography. This instrument was removed in 1887 to Harvard College Observatory, where it is now used for similar work under the direction of Prof. Pickering. Brooks, formerly of Phelps, N. Y., has made two reflectors, of 9 and 11 in. respectively, with which he has been remarkably successful in searching for comets, discovering 13 comets within 6 years. Brashear, of Allegheny, has made a number of very excellent reflectors with silvered-glass mirrors, ranging from 5 to 15 in. in diameter. He has also constructed several small refractors, and is now at work upon a 16-in. objective with "photographic correcting lens" for Carlton College Observatory. Dr. C. S. Hastings has figured several excellent objectives upon theoretical curves; his largest, of 9.4 in. aperture and remarkably perfect, is mounted at the Johns-Hopkins University.

Alvan Clark (*q. v.*), who has become famous as an optician the world over, began his career as a telescope-maker in 1846. In 1860 he finished a telescope of 18½ in. aperture, then the largest refractor known. In testing it Mr. Alvan G. Clark discovered the companion of Sirius, the existence of which had long been indicated by theory, though it had hitherto escaped detection. This first of the great Clark refractors was originally intended for the University of Mississippi, but, being prevented by the civil war from reaching its destination, it was purchased by the Chicago Astronomical Society and mounted at the Dearborn Observatory. In 1873 the Clark completed a 26-in. refractor for the U. S. Naval Observatory at Washington, the contract price for which was \$46,000; and, at the same time, they made for Mr. Leander McCormick an objective of a slightly larger aperture, which they mounted in 1883 at the University of Virginia. With the former instrument Prof. A. Hall discovered in 1877 the two small satellites of Mars. In 1879 the Clarks entered into a contract with the Russian government to furnish an objective of 30 in., and in 1880

with the Lick trustees for one of 36 in. The glass for all these large lenses is of foreign manufacture, coming from either Chance & Co., of Birmingham, or Feil & Co., of Paris; and considerable difficulty was experienced in obtaining disks of the requisite degree of purity, particularly in the case of the 36-in. crown glass disk, which involved nearly three years' labor and 19 failures before a suitable piece was obtained. Of smaller objectives the Clarks have made a great number—over 60, probably, between the apertures 6 and 12 in.

The mounting for the 30-in. Pulkowa objective was made by the Repsolds, of Hamburg; that for the Lick glass by Warner & Swasey, of Cleveland, Ohio. The following details of the Lick mounting are taken in part from an illustrated description of the instrument given in *Engineering* for Aug. 17, 1888:

The telescope is supported on a hollow cast-iron column of rectangular section, measuring 4 ft. by 8 ft. at the top, 5 ft. by 9 ft. at the floor line; then spreading rapidly to a base 10 ft. by 16 ft. bearing on the foundation. Around the top is a balcony, to which access is given by a spiral staircase. The objective in its cell weighs about $\frac{1}{2}$ ton, the column and head which carries the polar axis weigh together 21 tons, while the total weight of the telescope complete is 40 tons. The polar axis is of steel, 10 ft. long, 12 in. in diameter at its upper and 10 in. in diameter at its lower bearing, and having a hole 6 in. in diameter extending its entire length. Through this hole pass the shafts by which the observer at the eye end works the right ascension clamp and slow motion. The declination axis is also of steel, 10 ft. 6 in. long, 10 in. in diameter at its upper and 9½ in. at its lower bearing, and has a 4-in. hole extending through it. Bearings of Babbitt metal are provided for both axes, but much of the weight is carried by anti-friction rolls and an ingenious arrangement of "ball bearings." The telescope tube consists of a central section of cast-iron strongly ribbed, to which sections of sheet-steel are attached. When the telescope is horizontal the flexure of the tube with the object glass and permanent counter-balancing weights is $\frac{1}{4}$ in. only, while with a load of one ton added at each end the flexure is increased to $\frac{1}{2}$ in.

An observer at the eye end can perform the following operations:

1. Clamp in declination.
 2. Give slow motion in declination.
 3. Read the declination circle (2 verniers).
 4. Clamp in right ascension.
 5. Give slow motion in right ascension.
 6. Start or stop driving clock.
 7. Read the right ascension circle (1 microscope).
- An assistant on either side of the balcony can—
8. Clamp in declination.
 9. Give quick motion in declination.
 10. Give slow motion in declination.
 11. Clamp in right ascension.
 12. Give quick motion in right ascension.
 13. Give slow motion in right ascension.
 14. Stop or start driving clock.
 15. Read right ascension circle (2 microscopes).
 16. Read a dial showing approximate declination.

There are three permanent finders of 6 in., 4 in., and 2½ in. diameter respectively, and brackets are provided for attaching a 12-in. telescope belonging to the observatory when especially accurate pointing, as in some photographic work, is required. The eye end is further provided with a fine position micrometer made by Fauth & Co., and a stellar spectroscope by Brashear. The driving clock is in the upper section of the pier. The speed of the clock is regulated by a frictional governor of the cross-armed type and by an electric control, by means of which its rate is kept in agreement with that of a standard sidereal clock. One of the arbors, turning once in a minute, carries a chronograph drum.

For use as a photographic telescope a third (crown) lens of 33 in. clear aperture, weighing with the cell 150 pounds, is mounted in front of the visual objective, its application shortening the focal length of the telescope by 10 ft. An opening is therefore made in the tube 10 ft. from the eye end, and giving access to a plate-holder capable of carrying a plate 20 in. square, and provided with all the necessary adjustments. An image of the moon upon the plate is about 5½ in. in diameter.

The dome covering this great telescope is 70 ft. in diameter, and the floor can be raised vertically through a distance of 16½ ft. by four hydraulic rams. The observing slit is 9½ ft. wide, closed by two steel shutters, which are opened by a pull of 5 lbs. upon an endless rope. The cost of the visual objective was \$52,000, that of the photographic corrector \$13,000, while the mounting was furnished for \$42,000, and the dome and movable floor were put in place for \$73,300.

We have given a somewhat detailed description of this instrument for the reason that it may be regarded as embodying on a large scale all of the modern improvements and conveniences that have been introduced into telescope construction. Both Warner & Swasey and Fauth & Co. have furnished mountings for a number of Clark's smaller lenses, which are all that could be desired for ease of manipulation and steadiness.

Among improvements in astronomical instruments should be mentioned the "photoheliograph," a horizontal telescope of long focus, which was first brought into use by Prof. Joseph Winlock in 1869–70 at the Harvard College Observatory. A somewhat similar apparatus was previously suggested by Capt. Laussedat and others in France, but the peculiar advantages of this form of instrument for photographic observations of the sun do not seem to have been appreciated until the results of independent experiments at Cambridge had been published. Photoheliographs of 5 in. aperture and 40 ft. focal length, mounted in the meridian, were used by all the parties sent out by the United States to observe the transits of Venus of 1874 and 1880, and the superior results obtained by these parties seem to have justified the adoption of the "American method" of observation. A form of horizontal mounting for large reflectors, which appears to possess some of the advantages of Loewy's "equatorial coudé," was described by Mr. J. A. Hill at the meeting of the American Association for the Advancement of Science in 1871. The astronomer is enabled "to remain seated in one position, looking in one direction, and entirely protected from cold, fatigue, night air, etc." Prof. Pickering has used a horizontal telescope mounted at right angles to the meridian in his extensive photometric work, and for the continuation of this work to fainter stars he has recently had constructed by the Clarks an instrument of this kind of 12 in. aperture and 200 in. focal. The object glass is at the western end of the tube, and in front of it is placed a plane mirror, 18 in. in diameter, so mounted that the light of a celestial object not more than one hour either side of the meridian can be thrown into the field of the telescope. The eastern end of the tube, carrying the eye-piece, is covered by a small building, which can be warmed. An auxiliary telescope of 5-in. aperture is employed to bring into the field an image of the pole-star, which is reduced by polarizing apparatus to equality with the image of any star observed in the principal telescope. The angular apertures of the two telescopes are such that the emergent pencils may be coincident.

Photography has recently been developed into such a valuable accessory in astronomical observations that it becomes extremely desirable to provide means by which the ordinary visual objective may be readily transformed into a photographic objective, for the correction for chromatic aberration by means of the flint glass lens in the ordinary objective is too great to give

satisfactory photographic images. The method originally adopted by Rutherford and already mentioned in connection with the Lick glass, is to provide an additional convex lens of long focus, which may be placed over the ordinary objective when photographs are to be taken, and may be removed when direct observation is desired. Another method of getting rid of the excessive correction for chromatic aberration, suggested by Prof. Pickering, is to separate the flint and crown glass lenses and to place the flint nearer the eye-piece. While the color correction is in this way made satisfactory, the spherical aberration is only partially corrected, the focal length of the central part of the object glass being greater than that of the surrounding portions. This difficulty is, however, surmounted by making one surface of the crown glass lens much more convex than the other, and reversing it when the lenses are separated. An objective of 13 in. aperture ground in this way by the Clarks for the Harvard Observatory in 1887 has given most satisfactory results.

The principal makers of meridian circles, astronomical transit instruments, and zenith telescopes in America are Young, Würdemann (now retired), Stackpole, Buff & Berger, Fauth & Co., and Warner & Swasey. Fauth & Co. mounted in 1888 at the Cincinnati Observatory a 5½-in. meridian circle (object glass by Clark), the divided circle of which, as far as it has been investigated, compares favorably with the best of foreign make.

The following table will, perhaps, convey an idea of what may be expected of modern telescopes in "space-penetrating" or in "separating power;" the table gives the magnitude of the faintest star that telescopes of various apertures may be expected to show, and also the angular distance of the components of the closest double star that these apertures will just separate. [Note.—A star of about the 6th magnitude is the faintest visible to the unaided eye: a linear foot subtends an angle of 1" at a distance of about 39 miles.] The separating power was based by Dawes upon a number of experiments with small telescopes. The space-penetrating power is taken from Newcomb and Holden's *Astronomy*, and is computed upon the assumption that a star of any magnitude gives 2½ times the light of one of the magnitude next below.

Table of Space-penetrating and Separating Powers.

Aperture in inches.	Faintest star visible. Magn.	Least separable distance. "	Aperture in inches.	Faintest star visible. Magn.	Least separable distance. "

Where two makers are given, the first made the objective, the second the mounting. (W. C. W.)

TEMPERANCE REFORM. The beginning of the modern temperance movement may be traced to the publication, in 1785, of a work by Dr. Benjamin Rush, entitled *An Inquiry into the Effects of Ardent Spirits upon the Human Mind and Body*, which made a profound impression on thoughtful readers, and led in no long time to organized efforts for the suppression

of intemperance. There was abundant need; for though, from an early period in the history of the country, legislation had been directed to restricting the sale of intoxicating drinks, the evil had increased till it reached a portentous height. Strong drink was thought indispensable to laboring men. It was essential to reputable hospitality. It was plentifully supplied at weddings and at funerals, and even at ecclesiastical gatherings. Dr. Lyman Beecher describes an ordination which he attended early in his ministry in Connecticut. "The preparation for our creature comfort, besides food, was a broad sideboard covered with decanters and bottles, and sugar and pitchers of water. There we found all the various kinds of liquors then in vogue. The drinking was apparently universal. The preparation was made by the society as a matter of course. When the consociation arrived they always took something to drink round; also before public services, and always on their return. As they could not all drink at once they were obliged to stand and wait, as people do when they go to mill. There was a decanter of spirits also on the dinner-table to help digestion, and gentlemen partook of it during the afternoon and evening as they felt like it, some more and some less; and the sideboard, with the spillings of water and sugar and liquor, looked and smelled like the bar of a very active grog-shop. None of the consociation were drunk, but that there was not at times a very considerable degree of exhilaration I cannot affirm." One or two such scenes were enough to move Dr. Beecher powerfully, and the result was an organization proposed by the General Association for diminishing the use of spirits and for the reformation of manners. Similar action was taken about the same time by the General Assembly of the Presbyterian Church; and in 1811 the General Association of Massachusetts appointed a committee to co-operate with the committees of the Connecticut Association and the Presbyterian Assembly. Nothing more was proposed at this time than to restrain the *excessive* use of ardent spirits.

In 1813 the "Massachusetts Temperance Society" was formed—organized at first as the "Massachusetts Society for the Suppression of Intemperance;" the name subsequently adopted was indicative of more positive purposes, that were not long in being developed. In 1826 the "American Society for the Promotion of Temperance" was founded at Boston. Dr. Justin Edwards was appointed in 1829 corresponding secretary of this society, and travelled extensively, advocating total abstinence and forming State and local societies. This society later adopted the name, "The American Temperance Union," and has since been reorganized as the "National Temperance and Publication Society." The first national temperance convention, held in 1833, resolved "That the traffic in ardent spirits as a drink, and the use of it as such, are *morally wrong*, and ought to be abandoned throughout the world." But the movement had by this time acquired a momentum that made an advance necessary. In 1836 the national convention declared for total abstinence from all intoxicating drinks, and this became a settled "principle" of organized temperance. A powerful effect was produced upon the public mind. As a rule, the ministers of the different denominations and a large proportion of the communicants in the churches became pledged "teetotallers." Society took on a new face, and over a large part of the country the volume of the liquor traffic was materially diminished.

Up to this time the effort had been to prevent the formation of the drinking habit, by getting the young pledged against it. It was assumed that drunkards were irreclaimable. But in 1840 six men of intemperate habits in Baltimore signed a total abstinence pledge and founded the "Washington Temperance Society." The "Washingtonian" movement spread rapidly over the country, and it has been computed that 150,000 intemperate men were led to abandon

their cups. It was asserted, however, by observers of the movement that to a painful extent the reformation proved but temporary and was followed by relapses. More recent efforts in this direction have taken the form of what is termed "Gospel Temperance," in which it is sought to strengthen the moral appeal by the awakening of religious motives. In 1842 the order of the "Sons of Temperance" was formed, and in 1852 the order of "Good Templars," societies that have branched extensively and have had numerous imitators, in which the temperance principle is supposed to be reinforced by the machinery of lodges, pass-words, grips, and regalia, with pledges of mutual assistance.

But while very great and gratifying success had been gained, it was painfully evident that it was incomplete. There were still drunkards, there were still moderate drinkers who, in the general opinion of temperance men, were drunkards in the making, and there seemed to be no hope of abolishing the evil but by outlawing it. Massachusetts in 1838 passed an act prohibiting the sale of liquors in less quantity than 15 gallons, but it was repealed in 1840, leaving in force the former law forbidding the sale by unlicensed persons of liquor in less quantity than 28 gallons. Licenses were granted by city governments and by county commissioners. In 1843-46 a movement began for the election of commissioners opposed to license, and thus, without any change of the law, the sale of liquor became illegal in all the counties and cities of the commonwealth. A strong anti-license feeling was developed in New England, and rapidly spread through New York, Pennsylvania, Ohio, and several of the North-western States. But it was found that law, administered by the ordinary judicial processes and the ordinary rules of evidence, was ineffectual to arrest the traffic, and hence was originated a more inquisitorial law, raising presumptions against the accused in view of certain defined circumstances—a so-called prohibitory law, armed with heavier penalties. The first prohibitory statute was passed by Maine in 1851. With some modifications it has continued in force to the present time, and is generally approved by the people without distinction of party. Massachusetts followed the example by a similar act in 1852, which was soon repealed. But an act was passed in 1855 which proved impervious to legal criticism, passed the ordeal of the courts, and was declared constitutional by the U. S. Supreme Court. It continued in force 20 years, having been repealed in 1875. A local option law was substituted, under which every city and town (township) votes annually for or against license. As a rule a majority of the cities vote for license and a majority of the country towns against it. The result is that the sale is prohibited over two-thirds of the State. Between 1850 and 1860 prohibitory laws were passed by New Hampshire, Vermont, Connecticut, Rhode Island, Michigan, Ohio, Indiana, Illinois, Iowa, and Wisconsin; also in New York, where, however, it was declared unconstitutional by the Court of Appeals, and a license law was substituted.

The decade after 1850 was the period of highest success in all branches of temperance effort. The civil war had an unfavorable effect. While on the one hand there was a reaction from the theory and practice of total abstinence, there was on the other so complete absorption in the excitements of the war as to make the people unmindful of the change. The reaction was promoted by publications questioning the duty of total abstinence from fermented liquors. Foreign immigration had its effect, causing a manifest change in the character of our population. The wine of California and the products of foreign and domestic breweries powerfully solicited the appetites of the people. In 1840 the consumption of malt liquors per capita was 1½ gallons; in 1860, 3½ gallons; in 1880, 8½ gallons; in 1882, 10 gallons. Nevertheless, the friends of abstinence have not been disheartened, but hold

the most advanced ground. New Hampshire and Vermont retain their prohibitory laws, and some Western States. The local option system has had considerable success in the South, particularly in Georgia, though it seems difficult to keep the public mind steadily up to the work. The apparently capricious changes from prohibition to license and *vice versa* has led the friends of total abstinence to agree very generally in support of constitutional prohibition.

Kansas was the first State to embody in her constitution an article prohibiting the manufacture and sale of intoxicating liquors. Similar amendments have been put into the constitutions of Maine, Rhode Island, and Iowa; the Iowa amendment was annulled by the judiciary as not legally submitted to the popular vote. It is not easy to see the superiority of this method over statutory prohibition. No constitution executes itself; it can only be carried into effect by legislation appointing the process of enforcement and affixing penalties. The "statute in that case provided" is the operative measure. The prohibitory force of the statute is all the force that can be directed against the traffic, whatever superfluity of energy may be supposed to inhere in the constitution. In Rhode Island, the first Legislature that sat after the amendment was made was roundly accused of having virtually nullified the article, and a great popular agitation arose. Whatever may have been the fact in that case, it is clearly in the power of any Legislature, under color of carrying constitutional prohibition "into effect," to make laws as ineffectual as possible, whenever public opinion sets in that direction. Wisely or unwisely, however, the standard of prohibition by constitutional amendment is "full high advanced" as the sign in which they are to conquer, by all Prohibitionists in every part of the country. A prohibitory amendment to the Constitution of the United States is the ultimate aim.

A political party devoted to the cause of Prohibition as the one thing needful was a natural outcome of the agitation. The Prohibitory party, after some local enterprises, entered the field of national politics in the Presidential election of 1884. They chose no electors, of course, but they polled about 150,000 votes, and with extraordinary elation extended and perfected their organization with a view to further operations as a national party. In the Presidential canvass of 1888 they redoubled their energy and agitation on the "stump," through the press, and by the circulation of "documents." Success in electing their candidates was not claimed as probable. That was modestly deferred to the election of 1892. But the mark aimed at was a million of votes. The number cast was 257,243, a gain of 70 per cent. over the result in 1884.

Meanwhile an increased attention began to be given to what is termed "High license," as an expedient for restraining and diminishing the sale of intoxicants. The exaction of a large license fee as a minimum, coupled with stringent conditions, tends to restrict the number of licensed dealers, who are thus more easily kept under lawful supervision. At the same time the revenue derived from the traffic is some compensation for damages due to it; though it must be allowed that there is force in the objection, that for municipalities to derive a revenue from the traffic operates as a mercenary motive to license it. Where, as in Pennsylvania, the licensing power is committed to judges, the system has worked with beneficial effect. It is a question still disputed whether in other localities high license has had the effect to diminish the consumption of intoxicating drinks. Many friends of temperance favor it; Massachusetts has adopted it, and it is evident that the system must have its trial and abide the verdict from experience. Besides laws in restraint of the sale, a number of the States have adopted civil damage laws, the effect of which is to make the dealer in intoxicating drinks liable in damages for any injury resulting from the sale.

In 1873 the public mind was electrified by tidings

of a Woman's Crusade against the saloons, beginning in Ohio and spreading into the neighboring States. At first the grog-sellers cowered before the unexpected invasion, but recovering themselves they opposed this extra-legal assault. The agitation would probably have soon spent its force if opportunity had not been seized to transfer its energy into a well-devised organization under the name of the "Woman's Christian Temperance Union," which has become one of the recognized forces in the temperance warfare, and has extended its operations to the promotion of other reforms. The Union has done much to promote the education of the young in the principles and habit of abstinence; to secure legislation requiring such instruction in the public schools; and to add to the moral momentum of the temperance agitation. Of late, as a national organization, it has become an ally of the Prohibition party, and has declared for woman suffrage, which is espoused also by the Prohibitionists.

Total abstinence is a theory and a policy. As a theory it has had a remarkable evolution. At first, in view of the sin and misery of drunkenness, and the exposedness of men to temptation, abstinence was urged as the only security against the always impending peril. All drunkards, it was said, were once moderate drinkers, and none of them intended to become drunkards. And even if one could drink without peril to himself, he was besought from love to his neighbor to take the pledge with him and help him to keep it. Prudence and benevolence were the chief motives appealed to, and with remarkable success. These pleas were strengthened by evidence of economic damage and the social and moral evils resulting from intemperance. But, as early as 1833, as we have seen, a national convention resolved that "the use of ardent spirits as a beverage and its sale for that purpose are *morally wrong*." This empirical dictum of ethics was *resolved*, and now it is apparently assumed on all hands as needing no proof, that any sale or use of intoxicating liquors is a sin. But a large proportion of temperance men are also sincerely religious men, and reverence the Bible as an authority on moral questions, and it is but too obvious that on this ground the Bible is chargeable with the approbation of sin. To evade collision between their ethical theory and their faith in the Scriptures, the notion has been bruited and has found considerable currency, that there were in ancient times two kinds of wine, one unfermented and harmless and the other fermented and pernicious; and that when the Bible commands wine it means the harmless kind, but that when it speaks unfavorably of wine it refers to the fermented sort. The late Prof. Moses Stuart and Pres. Eliphalet Nott were the first vouchers for this strange theory. The scholarship of the age has repudiated this futile method of interpreting the sacred texts. It remains for its advocates to revise either their ethical dicta or their mode of interpreting and applying the Scriptures, or perchance to modify both. A development in another direction has been observable, though not perhaps distinctly formulated: a tendency to regard the drunkard not as guilty but as simply the victim of the liquor-seller. The latter is summarily described as a drunkard-maker. That an intemperate man has any responsibility for drinking is, if not denied, apparently forgotten.

As a policy, the temperance movement began its course as simply a moral reformation. The effort was to persuade men to leave off the use of intoxicating drinks, to give up the traffic, and to throw their social influence on the side of abstinence. Arrayed against it was the strength of appetite, of custom, and of the law. The form of license assumed that the sale of intoxicants was for "the public good," and applicants for license were required to furnish certificates to their "good moral character." The advocates of temperance faced this front of opposition, and by the force of their moral appeals won to their side the clergy, the churches, and a large proportion of the educated

and respectable, including no small part of the laboring classes, especially of skilled laborers. A great diminution in the sale and use of liquors was the result. But now a new purpose was taken up, which was nothing less than to suppress everywhere the manufacture and sale of intoxicating drinks. Hence law, more law, and, finally, constitutional law, have been invoked, and until the desired end is reached the agitation is to go on. Whether this is not an utterly impracticable purpose; whether any law can be devised that will prevent men from gratifying the appetite for stimulants as long as the appetite exists; are questions to which in their present temper the leaders in the temperance warfare will scarcely vouchsafe a hearing. But those who are willing to think may be led to doubt whether legal penalty is superior to, or in any degree a substitute for, the appeal to moral, religious, and affectional motives, and the cumulative force of enlightened public sentiment—whether in short there is any more effective prohibition than a man imposes upon himself.

There are many earnest temperance advocates and workers who cannot believe it right to proscribe wine, which our Lord and his apostles used, and which is made a symbol by the Holy Spirit of spiritual joy. Hence, they will not join in any movement of teetotalism or prohibition which is indiscriminating in this regard. They are ready to use every reasonable means to diminish the evils that come from the excessive use of intoxicants, and to put heavy restraints upon the sale of distilled liquors. These temperance advocates also are opposed to the one-sidedness of a reform that puts one sin forward out of all proportion to other sins and so tempts many to suppose that if this sin is avoided the man is renewed. They believe all sins should be classed together as odious to God and injurious to man, and that the social vice, greed for wealth, and fraud are doing as much to destroy society as is intemperance. Against all every effort should be put forth for their overthrow and the establishment of righteousness.

The temperance movement was carried beyond the Atlantic, and appeared in Scotland in the formation of a temperance society near Glasgow in 1829; the first total abstinence society was formed at Dunfermline in 1830. The first temperance society in Ireland was organized at New Ross, County Wexford, in 1829; the first total abstinence society at Strabane, in 1835. The celebrated Father Theobald Mathew began at Cork, in 1838, those labors which made his name a household word in the Old and the New World. He rapidly extended his labors to all parts of Ireland with such effect that the society formed by him contained in 1840 1,800,000 persons pledged to total abstinence. The consumption of whisky in Ireland fell from 12,500,000 gallons in 1838 to 6,500,000 in 1841. In 1843 the number of persons pledged to total abstinence through the labors of Father Mathew in Ireland and in Great Britain exceeded 5,000,000. In England, beginning in 1830, local associations were formed at Bradford, Manchester, Liverpool, and Leeds. "The British and Foreign Temperance Society" was formed in 1831, with the patronage of the Bishop of London, and the support of many persons high in rank and official station, pledged to abstain from distilled spirits except for medicinal purposes. Total abstinence and "teetotal" societies were formed in 1835. "The New British and Foreign Temperance Society," formed in 1836, had originally two pledges, but in 1839 the total abstinence pledge was adopted. Both general societies adopted this pledge in 1840, and a great impulse was given to the movement. The cause has since been carried forward by the agency of several efficient organizations in different parts of England, laboring by means of lectures, publications, and petitions to Parliament. The "United Kingdom Alliance," formed in 1853, aims at "the total and immediate suppression of the traffic in all intoxicating liquors as a beverage,"

though the practical efforts it has put forth have been for the enactment of the "Permissive Bill," corresponding nearly to our local option laws. It proposes to prohibit the licensing of the traffic in any parish in which two-thirds of the rate-payers shall so determine. This moderate and reasonable measure stands no chance of being enacted at present. Great as has been the increase of pledged abstainers, the movement is far from having permeated religious and general society to the extent that it has in this country.

Whatever opinion may be entertained of the theories or the policies of organized temperance, it cannot be doubted that a highly beneficial change has been produced in the habits of the people. During forty years, from 1810 to 1850, there was a very great reduction in the quantity of intoxicating liquors consumed in the country. Of distilled spirits the consumption fell from 4.6 gallons to 2.5 gallons per capita, and, including all intoxicants, there was a decrease per capita from 8 to 4.1 gallons. It would be a great error to suppose that the real strength of temperance principle is to be measured by the number of political prohibitionists. It is not uncommon to find persons who have grown up to mature manhood without having ever known the taste of intoxicating drink, or feeling the slightest inclination to acquire it. The great body of moral and intelligent men and women of our native stock are abstainers from principle, and much as our composite population now complicates results, an assimilation is going on among the foreign elements of our commonwealth to the native American standard.

The literature of Temperance is enormous. Beginning with Dr. Rush's pamphlet (1785), Dr. Heman Humphrey's *Six Sermons* (1810), and Dr. Lyman Beecher's *Six Sermons on Intemperance* (1785), the reverberation of which went literally around the world, it includes discourses and essays by leading ministers of all denominations, and by eminent civilians and jurists, reports of national and local organizations, some of them productions of eminent ability and permanent value, and discussions in periodicals. Of recent works two are of special value: *History of the Temperance Reform*, by Hon. Henry W. Blair, and *The Liquor Problem in All Ages*, by Daniel Dorchester, D. D. (L. E. S.)

TEMPLE, FREDERICK, English bishop, was born at Santa Maura, Nov. 30, 1821. He was educated at Balliol College, Oxford, and graduated B. A. in 1842, being then elected fellow and mathematical tutor of his college. He was ordained priest in 1847 and became principal of Kneller Hall Training College from 1848 to 1855. In 1858 he was appointed head-master of Rugby School and discharged the duties of this position with marked success. He was one of the seven authors whose *Essays and Reviews* (1860) revealed the increase of Broad church views and rationalistic tendencies in the Church of England. His essay was on "The Education of the World." He also published three series of *Sermons Preached in Rugby Chapel* (1862-71). In 1869 he was made bishop of Exeter, and in 1885 he was transferred to the see of London. He was select preacher at Oxford in 1873, and Bampton lecturer in 1884.

TENNENT, GILBERT (1703-1764), and WILLIAM (1705-1777), were sons of Rev. William Tennent, a Presbyterian minister who emigrated from Ireland in 1718, and founded a "log college" near Philadelphia for the training of students in divinity. Gilbert, after teaching and being taught there, was ordained pastor of a Presbyterian church at New Brunswick in 1726. Here his brother William while studying theology fell into a trance and was for some days supposed to be dead. He revived, however, and afterwards declared that he had been admitted to heaven and gave some description of his vision. Meantime he had lost his knowledge of earthly things and had to be trained as a child. Having fully recovered he was in 1733 ordained pastor of a church at Freehold, N. J., and there continued until his death, March 8, 1777. Gilbert in 1740 at the request of Whitefield became an evangelist and travelled in New England. His doctrinal

peculiarities and perhaps his eccentricity in dress and manner roused opposition to him and the Presbytery of New Brunswick was divided. In 1743 he founded a church at Philadelphia but still travelled widely. The Log College had been merged in Nassau Hall at Elizabethtown, N. J. and afterwards at Princeton, and in behalf of this institution Tennent went to England, Scotland, and Ireland in 1753, and obtained liberal donations. He died at Philadelphia, July 23, 1764. He had published many sermons and an account of the revival of religion in 1741.

TENNYSON, ALFRED, BARON, the representative poet of the Victorian era in English literature, was born at Somersby, a small hamlet of Lincolnshire, Aug. 6, 1809. He is the third of seven sons in a family of twelve children. Lord Tennyson is descended, through the Barons D'Eyncourt, from the ancient and illustrious Norman Plantagenets. The poet's father, the Rev. George Clayton Tennyson, LL. D. (d. about 1831), rector of Somersby and vicar of Grimsby, was notable in many ways. He was a striking, impressive man of great strength and stature, an excellent mathematician and linguist, something of an architect, musician, painter, and poet, and, withal, a man of fine character, "high-souled, high-tempered." Tennyson's mother was Elizabeth, daughter of the Rev. Stephen Fytche, vicar of the neighboring parish of Louth, "a sweet, gentle, and most imaginative woman, exceedingly tender-hearted, intensely, fervently religious—as a poet's mother should be." Thus the genius of Alfred Tennyson, shared, as it was, in some measure by most of his many brothers and sisters, would seem to be inherited in some degree from each of his parents; for if the fine physique, the scholarly tastes, the high character, and the artistic temperament of the illustrious son are traceable to his father, surely his surpassing imagination and his unspeakable tenderness—without which his greatness as a poet would have been impossible—are as plainly traceable to his mother.

Dr. Tennyson's "handsome children had beyond most children that wondrous toy at their command which some people call imagination." They were given to games typifying the exploits of legendary kings with their retinues of knights, and beguiled their happy childhood with tales and romances of their own making fashioned after mediæval models.

As to Tennyson's education, the central fact is that he has been pre-eminently self-taught. Not that he has lacked regulation teachers and tutors, but that he early began to supplement their instruction by self-instigated reading, observation, and reflection; and that he has shown from boyhood a growing independence of mind and character. Early in life he as good as recorded of himself that knowledge to him was beautiful, and that he loved it "for its beauty." To any one with the slightest appreciation of Tennyson's love for the beautiful this autobiographical bit is sufficient to account for the powerful affinity his mind has ever shown for knowledge. Such a soul, after a first start, may safely be left to itself. This start in Tennyson's case was obtained largely at home under the tuition of his father, though he attended for a time Caducey's village school, and for a brief period the grammar-school at Louth. The young lad's poetical bent was greatly stimulated by the similar bent of his elder brothers, Frederick and Charles, both of whom have written verse of much merit. As boys they were all great readers of poetry, ancient and modern, Alfred being particularly partial in those years to Scott and Byron; and they were all furthermore copious writers of metrical compositions. Alfred's boyish efforts were very numerous.

In 1827 Charles and Alfred published selections from their accumulated productions, under the title, *Poems by Two Brothers*. This little book, for which the young authors received from their publishers £10, contained 228 pages, and bore on its title-page the disclaimer quoted from Martial, "*Hæc nos novimus esse nihil*."

The preface explained that the poems were composed not jointly but individually, and that they were written between the ages of fifteen and eighteen. The body of the work is remarkable for its numerous foot-notes and quotations from ancient and modern poets—but chiefly for the entire absence of anything characteristic of the later work of England's Laureate. The volume is interesting chiefly as showing the 'prentice hand of Alfred Tennyson. The critics of that day, with one exception, passed it by in utter silence. That it contained little or nothing worthy, on its own merits, of further perpetuation is now the practically unanimous verdict, Tennyson's not excepted; for he has never seen fit to reprint or to publicly acknowledge so much as a single poem contributed by him to this first volume.

About 1828 Alfred, with Charles, removed to Trinity College, Cambridge, where the eldest brother Frederick had just taken the Chancellor's medal for his Greek poem, *Egypt*. Here Alfred soon became a recognized leader among a circle of young collegians remarkable for high character, and for vigor and brilliancy of intellect. Among them were Arthur Henry Hallam, who will be forgotten only when *In Memoriam* fails for readers; Lord Houghton, then Richard Monckton Milnes, sometimes styled the "Mæcenæ of his time;" Richard Chenevix Trench, afterwards Archbishop of Dublin; Henry Alford, James Spedding, Merivale, the historian; Edward Fitzgerald, and Kinglake. Thackeray, for years a warm personal friend and a great admirer of Tennyson, was also a fellow-student at Cambridge; their close intimacy, however, seems to have dated from a subsequent period. Alfred's tutor at college was William Whewell, "a man who is well known to have stripped the tree of knowledge and tasted most of its substantial fruits." Tennyson and others of the students above mentioned belonged to an undergraduate society commonly known as the "Cambridge Apostles," from the limitation of its active members to twelve; the main object of which was full and frank discussion of those questions which, in the bold and vigorous minds of its members, were pressing for solution. It appears probable that Tennyson in his university career was much more given to wooing the muses than to pursuing any prescribed routine course of study; but it is also probable that in disregarding conventionalities he was consciously following the mandates of his own genius, which, however lawless it might make him appear to others, was an all-sufficient law unto itself. When at length he quitted the university it was without a degree. The same was true of Thackeray. Thus the two most widely known Cambridge men of this century left their *alma mater* without the customary seal to their fidelity and of her approval—but destined to win loftier honors and more enduring laurels than any ever won or bestowed in college.

In 1829 Tennyson was awarded the Chancellor's medal for his poem *Timbuctoo*, one of the unsuccessful competitors being his nearest friend, Arthur Hallam. The poem received a very flattering notice from the *Athenæum*. The author did not, however, include it in subsequent collections of his poems.

In 1830, while still at Cambridge, Tennyson published his *Poems, Chiefly Lyrical*. This volume contained *Lilian, Isabel, Mariana, The Mermaid, The Merman, The Mermaid, The Owl, Recollections of the Arabian Nights, Ode to Memory, The Poet's Mind, The Deserted House, The Ballad of Oriana, The Sea Fairies, Nothing Will Die, All Things Will Die, The Dying Swan*, together with twenty-five poems which the author did not republish in subsequent collections. All the "rejected poems"—indeed, every collectable scrap Tennyson has ever written—now appear in recent American editions. The volume of 1830 soon drew the fire of the critics, from some of whom it received hearty though discriminating praise.

As originally proposed the "Poems" were to have been a joint publication by Tennyson and Arthur

Hallam as a memorial of their friendship. This plan was abandoned at the suggestion of Hallam's father. Hallam, however, reviewed his friend's volume in an essay "On some of the Characteristics of Modern Poetry, and on the Lyrical Poems of Alfred Tennyson," which appeared in the *Englishman's Magazine*. To those who would account for Tennyson's surpassing affection for his friend this essay is exceedingly interesting. Hallam notes five distinct excellencies in Tennyson's manner: his luxuriance of imagination and his control over it; his power of embodying himself in ideal characters; his vivid picturesque delineation of objects, and the peculiar skill with which he holds all of them fused in a medium of strong emotion; the variety of his lyrical measures, and exquisite modulation of harmonious words and cadences to the swell and fall of the feelings expressed; the elevated habits of thought, implied rather than directly expressed, and more impressive than if the author had drawn up a set of opinions in verse, and sought to instruct the understanding rather than to communicate the love of beauty to the heart. Hallam's prophetic allusion in verse to his companion is worthy of mention:

"A friend, a rare one,
A noble being full of clearest insight,
Whose fame
Is couching now with pantherized intent,
As who shall say, I'll spring to him anon
And have him for my own."

Leigh Hunt paid Tennyson's first volume the compliment of an extended review. Yet the poet's course has not been a continuous ovation. Even Coleridge wrote: "The misfortune is that he has begun to write verses without very well understanding what metre is."

About this time Tennyson and Hallam made a journey to the Pyrenees in the interest of the Spanish patriots driven into revolt by the tyranny of Ferdinand. They were the bearers of money and of despatches in invisible ink to the conspirators who were then hiding in the mountains. This episode is referred to in *In Memoriam*, *In the Valley of Canterbury*, and in the poet's letter to his commentator, Mr. Dawson, of Montreal.

In the winter of 1832 a second volume appeared, containing thirty poems; among them *The Lady of Shalott*, *The Miller's Daughter*, *Enone*, *The Palace of Art*, *The May Queen*, *The Lotus Eaters*, and *A Dream of Fair Women*. Of this little book one of the most competent of modern critics (himself a poet) has said: "All in all, a more original and beautiful volume of minor poetry has never been added to our literature." It is difficult for those whose memories cover only that portion of Tennyson's career since his powers have been abundantly acknowledged and his fame assured to realize that there was a time when not merely the world but the majority even of the readers of poetry were quite indifferent to the feasts which he prepared for them; that a taste for such spiritual delicacies had actually to be cultivated, and that right slowly and painfully. Such is the case, however, as is shown in the world's willingness to let ten years elapse before calling for a second edition of this exceptional volume. Here and there, however, might be found a man, and, very rarely, even a critic, who regarded Tennyson as the chief living hope of the muses.

In 1833 Arthur Hallam, the poet's brother in the kinship of sympathy—and the betrothed lover of his sister Emily—died while absent in Vienna. This bereavement, so sudden, sharp, and unexpected, following fast upon other similar visitations, produced a most profound impression on the sensitive, thoughtful mind of the poet, bringing him face to face and at closest quarters with the awful Sphinx, propounding the great riddle—Death—and the even greater riddle—Life. Tennyson's answer—and no grander has been recorded in our age—is to be found in *In Memoriam*. The ten years following 1832 was a period of silence, though by

no means one of inactivity. The poet's life during these ten years was one of the greatest seclusion. "Avoiding general society, he would prefer to sit up all night with a friend, or else to sit and think alone. Beyond a very small circle he was never met." This circle, however, was as select as it was small. It included Thackeray, Landor, R. H. Horne, Carlyle, Sterling, Macready, Cunningham, Forster, and Mill. Tennyson and Carlyle used to have sundry "wit combats," "interlarded," according to their own accounts, with "brilliant flashes of silence." At length the plodding poetic world so far caught up with her great apostle as to demand a new edition of his poems. This was met in 1842 by the publication of a selection from the contents of his two previous books, carefully revised, with several new poems, among which were *Lady Clara Vere de Vere*, *The Blackbird*, *The Goose*, *Ulysses*, *Love and Duty*, *The Two Voices*, *The Talking Oak*, *Morte d'Arthur*, *The Gardener's Daughter*, *Dora*, *St. Simeon Stylites*, *Locksley Hall*, *Godiva*, and part of *The Day Dream*. The reception given these two volumes by the most thoughtful of the English-speaking race everywhere was prompt and appreciative. Fine as had been the quality of his previous work, it was seen that he had improved even upon that. Three further editions of the "Poems" were called for within four years, and Moxon, his publisher, said, as early as 1843, that Tennyson was the only poet by whom he had not lost. About this time the future laureate met, for the first time, his great predecessors. The high opinion of each respecting the other is shown in one of Wordsworth's letters to Prof. Henry Reed, of Philadelphia, in which he says: "I saw Tennyson when I was in London several times. He is decidedly the first of our living poets. You will be pleased to hear that he expressed in the highest terms his gratitude to my writings."

One thoroughly human phase of genius is well shown in the "literary squabble" between Bulwer-Lytton and Tennyson which followed the bestowal of a pension upon the latter in 1845. The curious may learn particulars by referring, in old editions, to *The New Timon*; a *Romance of London*, and to Tennyson's rejoinder, *The New Timon and the Poets*. But the wrath of the truly great is apt to be as momentary as it is intense. The *After-thought*, since rechristened *Literary Squabbles*, following speedily upon Tennyson's *New Timon*, shows his humility as well as his wisdom in such matters. A further sequel to this episode is to be found in Tennyson's dedication of his *Harold*.

In 1847 *The Princess* appeared; a poem well worthy of profound study by all who find themselves perplexed over the question of woman's proper "sphere." Three important events mark the year 1850. On June 13 Tennyson was married to Miss Emily Sellwood, whose mother was a sister of Sir John Franklin. The bride was "the near, dear, and true" of *The Dedication* in *Enoch Arden*. She proved a woman eminently qualified to have in her keeping a poet's comfort and happiness. Few men of letters have been so singularly fortunate in the choice of a helpmeet. The second event of 1850 was the publication of *In Memoriam*. Those who make of this work merely a monument to Arthur Hallam's memory underestimate its weighty import. Such a monument it is, of course, but it is vastly more: it is Tennyson's rendering of Job—destined to endure as long as men turn for enlightenment and consolation to the scriptures of the nineteenth century. *In Memoriam* instances well the slow and painful evolution of those things which are vital and lasting. Even a Tennyson took seventeen years to write *In Memoriam*; and the sadness and sorrow of some of those years are a subject too sacred to be publicly intruded upon. It was in 1850 that Tennyson succeeded Wordsworth as poet-laureate, an office which he has greatly honored, though not by the amount of work done strictly in his official capacity. The best known of his

laureate poems are the *Ode on the Death of the Duke of Wellington*, and *The Charge of the Light Brigade*.

In 1855 appeared, with other poems, the monodrama *Maud*, the full-blown blossom of which the stanzas "Oh, that 'twere possible," so rapturously alluded to by Mr. Swinburne, had been the beautiful bud. This fair flower of Tennyson's genius was eighteen years in opening. Those who feel the need of help in arriving at the true meaning of *Maud*, which has been much misunderstood, may find the essay of Dr. R. J. Mann of assistance; this essay received high commendation from the poet.

The *Idylls of the King* afford another instance of the slow growth of great works of art. The germ from which these sprang had a very definite existence in the mind of the poet at an early period; the maturing of the product of that germ was well-nigh the work of a lifetime. The first instalment of the *Idylls* appeared in 1859; four more were added in 1869, while the series complete was not given to the world until 1872. These Arthurian poems, constituting as they do in a very real sense an epic, are by many considered the poet's masterpiece. Of *Guinevere* Bayard Taylor has said that it would die only with the language in which it was written.

Enoch Arden, with other poems, came out in 1864. This poem, translated as it soon was into French, German, and even into Latin, has been so widely read that its very title has passed into a proverb. In 1870 appeared *The Window, or the Songs of the Wrens*, with music by Arthur Sullivan.

Tennyson's work as a dramatist comprises *Queen Mary* (1875); *Harold* (1877); *The Fulcrum* (1879); *The Cup* (1881); *The Promise of May* (1882); and *Becket* (1884). The dramas are often spoken of as the Laureate's "least successful" work. Curiously enough many criticisms of them seem based on the preconceived notion that Tennyson could not write a drama. Others have thought him, with his weight of nearly threescore years and ten, too far advanced in age to attempt the gathering of fresh laurels in a new field. Nevertheless, some of the dramas are highly regarded by sundry good authorities, and the author, it is said, believes them to contain his best work.

In 1879 *The Lover's Tale*—written in 1829, privately printed in 1833, pirated and misprinted in 1875—was reluctantly placed at the disposal of the public, together with its sequel, *The Golden Supper*. In 1880 the richly various volume, *Ballads and other Poems*, came out, evidencing the singular persistence of Tennyson's powers. Concerning *Rizpah*, in this collection, Mr. Swinburne says: "If after a thousand years all trace of all his poems had vanished from all human record save only these eighty-six lines of *Rizpah*, proof positive and ample and overflowing would be left in the survival of these that in him, if ever upon earth, a great poet had been born. . . . Never since the very beginning of all poetry were the twin passions of terror and pity more divinely done into deathless words. . . . The poet never lived on earth whose glory would not be heightened by the attribution of this poem to his hand." This is high praise, and it proceeds from a high source; from a rival, it might be said, were rivalry possible in the highest art.

Tiresias and Other Poems, dedicated to Robert Browning, appeared in 1886, and also in the same year *Locksley Hall Sixty Years After*, a recantation in some degree of the poet's early dreams of the progress of the world.

Alfred Tennyson has been one of the men whom the world has shown a growing delight to honor. His career affords a study in the concrete of the way in which all things are added to those who seek first that which is highest and best. In 1845 the value of his work and influence received recognition from the state in the award of a pension, and in 1850 in his appointment as Laureate. In 1855 the University of Oxford conferred upon him the decree of D. C. L. In 1865

he was elected Fellow of the Royal Society. The same year a baronetcy was offered him, which, however, he did not accept. The offer was repeated three years afterwards, and was again declined. In 1869 he was elected honorary fellow of his *alma mater*, Trinity College, Cambridge. In 1880 he was invited to stand for the Lord Rectorship of Glasgow University, but, the candidature involving his identifying himself with a political party, he declined the honor. In 1884 he was made president of the Incorporated Society of Authors. In the same year he was raised to the British peerage under the title Baron Tennyson of Aldworth and Farringford, a fitting and graceful recognition of his eminence in the world of thought and genius.

Concerning Tennyson's private life there is little to be said. For many of the years after leaving Cambridge he had no settled place of abode. Much of that time he lived in London with poverty and his golden dreams. His early married life was spent in Twickenham, which place he has made "twice classic." For upwards of thirty years he has lived at Farringford, Isle of Wight, and at his summer residence, Aldworth, in Surrey. Recluse as he has been, a few congenial spirits have found in him the prince of companions. Those who have been admitted to this charmed circle prize him as a man fully as much as they admire him as a poet. He is a penetrating judge of character, and knows instinctively, it is said, everything that is going on about him. He is fond of reading his poetry to appreciative listeners. His rendering is described as a mysterious incantation, exceedingly impressive, leaving the listener with the feeling that he has for the first time heard what he may have already read, perhaps, a hundred times. With his personal appearance the world has been familiarized by his numerous pictures. That the best of these, however, fail to do justice to the fine face is evident from the descriptions of those who have seen that face under the play of the passions within. Thomas Buchanan Read describes the poet's head as that of "a dilapidated Jove."

Of Tennyson and his work it is embarrassing to try to speak in general terms. The subject presents the double danger of falling into extravagance and yet of failing to do it justice. Disclaiming all attempt to adequately discuss it here, it may be remarked that Tennyson's poetry is pre-eminent for its beauty and for its power. On the first of these heads let the poetry speak for itself. Passing to the second, we characterize Tennyson's poetry pre-eminent in power because none of his contemporaries has touched so deeply and at so many points the hearts of the people of all ranks, classes, and conditions. Others have moved the masses; still others have been the pride of their own "restricted audiences." Not one, however, as this great minstrel, has so won the hearts of *all*. Is he, then, a "popular" poet? Yes; but not in the disparaging sense. Is he the apostle to the aristocracy? Yes; to the aristocracy of intelligence and virtue. Take up the collection of poetry—*Farnassus*—which shows the personal taste of that lofty intellectual aristocrat, Ralph Waldo Emerson: in it the greatest among other living poets are accorded but about quarter the space accorded to Tennyson; take up any modern "fireside" collection, the proportion will be found about the same. The wide influence of the poet is further shown by the *Complete Concordance* to his works, published in 1869; by the numerous translations his works have undergone into most of the languages of Europe, and by the willing aid which the kindred arts—music, sculpture, and painting—have lent to the illustration of his poetry.

In conclusion let us poll the jury of the poet's peers. Wordsworth: "He is decidedly the first of our living poets." Browning: "In poetry, illustrious and consummate; in friendship, noble and sincere." Mrs. Browning: "He is a divine poet; if anything were to happen to Tennyson the world should go into mourning." Swinburne: the high tributes already

quoted. Rossetti: "The greatest poet of the period." Thackeray: "The wisest man I know." Dickens: "What a great creature he is! . . . A great living poet, who uses his great gifts, as he holds them in trust, for the general welfare." Landor: "Infinite his tenderness, his thought, his imagination, the melody and softness as well as the strength and stateliness of his verses." Carlyle: "One of the few British and foreign figures who are and remain beautiful to me—a true human soul, or some approximation thereto, to whom your own soul can say, 'Brother!'" Gladstone: "His life and labors correspond in point of time as nearly as possible to my own, but his exertions have been on a higher plane of human action than my own. He has worked in a higher field, and his work will be more durable." Emerson: "Tennyson has incomparable felicity in all poetic forms. . . . Nay, some of his words are poems." Lowell: "It may be centuries before such a thinker and speaker as Tennyson appear." Stedman: "Certainly to be regarded in time to come, as, all in all, the fullest representative of the refined, speculative, complex Victorian age." That age has been widely deplored as grossly materialistic. Let those who can make of it nothing else or better ponder on the exaltation which has overtaken the humble youth

"That did love Beauty only." (C. E. W.)

TERHUNE, MARY VIRGINIA, novelist, better known by her pen-name, "Marion Harland," was born in 1835 in Amelia co., Va., her maiden name being Hawes. From her earliest years she was given to writing, and when she was 16 she had a story accepted for *Godley's Lady's Book*, which was translated into French, re-translated into an English periodical, and finally copied in America as an English tale. Encouraged by this singular success she determined to write a novel. This was published in 1854, under the title, *Alone*, and at once created a sensation, while since that time upwards of 100,000 copies have been sold. In 1855 she produced *The Hidden Path*, which also had a large sale. In 1856 she was married to Rev. Edward P. Terhune, then a minister at Charlotte Court-House, Va. Marriage and its duties did not check her prolific pen. In 1857 her *Moss-Side* appeared, and this was followed in rapid succession by *Nemesis*, *Husks*, *Husbands and Homes*, *Sunnybank* and *Christmas Holly*, *Ruby's Husband*, *Phemie's Temptation*, *At Last*, *The Empty Heart*, *Jessamine*, *Handicapped*, *A Gallant Fight* (1888), eighteen novels in all, every one of a pure and elevating character. In 1858 Dr. Terhune was called to a church in Newark, N. J., where he and his family spent eighteen years. Two years were then devoted to travel and residence in Europe, which furnished material for a book called *Loiterings in Pleasant Paths*.

On his return Rev. Dr. Terhune received a call to the First Congregational Church of Springfield, Mass., and five years later to the Bedford Reformed Church, Brooklyn, N. Y., where he and his wife still reside, actively engaged in Christian and philanthropic work. Besides her novels "Marion Harland" has been noted for her counsel to housekeepers. Her *Common Sense in the Household* had an immediate success; 150,000 copies have been sold in America and half that number abroad, and it has been translated into Arabic, French, and German. Kindred works, constituting the Common Sense Series, have come from her pen, comprising *Breakfast, Luncheon and Tea*, *The Dinner Year Book*, *The Cottage Kitchen* (1883), and *Cookery for Beginners* (1885).

TERRAPIN. See TORTOISE.

TERRE HAUTE, a city of Indiana, seat of Vigo co., is on the left bank of the Wabash River, about 175 miles from St. Louis, Chicago, Cincinnati, and Louisville respectively. Nine railroads connect it with these and other places. The city is on a plateau 60 feet above the river, which is here crossed by three

bridges. It contains a U. S. government building, a handsome court-house, opera-house, 5 hotels, 3 national banks, 2 other banks, and 27 churches, some of which are fine structures. It has fourteen schools, whose property is valued at \$244,000; also the Indiana State Normal School, St. Mary's Institute, Coates College, Rose Polytechnic Institute, Rose Orphans' Home, and St. Anthony Hospital. Two daily and 4 weekly newspapers are published here. There are 7 foundries, 23 factories, and many mills, the total of industrial establishments being 125. The proximity of the block coal-mines of Clay county favors manufactures. The city has gas- and water-works and two parks. The property is valued at \$15,000,000; the public debt is \$283,000, and the yearly expenses about \$200,000. Terre Haute was settled by French colonists, an offshoot from Vincennes, Ind. Col. Francis Vigo (1740-1836), from whom the county was named, was a merchant here and advanced the funds for Gen. George Rogers Clarke's expedition against Kaskaskia. Terre Haute in 1880 had a population of 26,042.

TERRITORY. This article treats of the title of the United States to their territory and of the formation of territorial governments. The greater part of North America was claimed by the sovereign of Great Britain on the ground of its discovery by British subjects. The grant to Sir Walter Raleigh in 1584 of lands not held by any Christian prince or people and title to such as should be discovered under that authority resulted in no permanent establishment.

The first charter of Virginia, in 1606, granted the sea-coast of America from the 34th to the 45th degree of latitude to two companies termed the first and second colonies, the first colony to be established between the 34th and 41st degrees, and the second colony between the 38th and 45th degrees, but not less than 100 English miles apart. The western limit of this grant was indefinite. The second charter of Virginia, in 1609, defined more exactly the grant to and powers of the first colony, limiting it territorially to 200 miles north and the same distance south of Point Comfort, extending into the land from sea to sea. The third charter of Virginia, in 1611, was to the first colony and confirmed the terms of the second charter as it regarded the territory granted, but added that it should extend "from sea to sea, west and north-west," and also added certain islands. The first company, originally known as the London Company, organized under the second charter as the South Virginia Company. The second company was the Plymouth Company that settled New England.

The charter of New England, in 1620, was to the second colony under the Virginia grant, and its objects were to make the colonies independent of each other and to make partition of their territory between them, which had been partially accomplished by the second charter of Virginia. The territory granted under this charter was denominated New England, and was to extend from the 40th to the 48th degrees of latitude.

A charter was granted to the colony of Massachusetts Bay in 1629, embracing that part of the coast of New England between the Merrimac and Charles Rivers and extending beyond them respectively three English miles. This charter, intended to confirm a grant from Plymouth colony, was annulled in 1684 and a new charter granted in 1691. The last mentioned charter granted to Massachusetts Bay and Plymouth colony the Province of Maine and Nova Scotia and as far south as Rhode Island and Connecticut, including Cape Cod and westward to the South Sea.

Massachusetts was one of the original colonies and became a State at the Revolution.

New Hampshire was settled under grants from the Plymouth colony, confirmed by the crown in 1629, and became an independent colony in 1675 by royal decree, and became a State at the Revolution.

Rhode Island was settled under a patent of the Providence Plantations issued under the authority of

Parliament in 1643. It was chartered by the crown in 1663 and became a State at the Revolution.

Connecticut was settled and established as a government under commission from the General Court of Massachusetts in 1636 and asserted its independence in 1638. It was recognized as an independent colony by royal charter in 1662 and became a State at the Revolution.

Maine was constituted of territory of the Plymouth colony. In 1639 the Province of Maine was granted by the crown to Sir Ferdinando Gorges, as lands unoccupied under the New England grant, and in 1664 was granted to the Duke of York, together with land now occupied by the State of New York, which grant was confirmed in 1674. In the charter to Massachusetts Bay in 1691 Maine was confirmed to that colony, and in 1819 was made independent by an act of the Legislature of Massachusetts confirmed by popular vote. In 1820 an act of Massachusetts, confirmatory of her previous cession, consented to the admission of Maine as a State, and she was admitted in that year. The boundary of Maine where touching upon the British possessions was in dispute for many years, and was finally adjusted in the treaty with Great Britain of 1842.

Vermont.—The territory and jurisdiction of this colony were disputed between Vermont, claiming to be independent, and Massachusetts and New Hampshire, claiming in right of the Plymouth title, and New York in right of the Duke of York. These claims were finally relinquished, and Vermont was admitted as a State in 1791.

New York, which was originally settled in part and claimed by the Dutch, was, under a purchase made by the Duke of York from the Earl of Stirling, claimed by the Duke, who, in 1664, took forcible possession of New Amsterdam, and his title was finally confirmed by the second grant to him in 1674. New York was one of the original colonies and became a State at the Revolution.

New Jersey was originally settled by the Dutch, but was claimed by the Duke of York under his grant of 1664 and sold to Lord Berkeley and Sir George Carteret, the title of the duke being confirmed by the grant to him of 1674. New Jersey was an original colony and became a State at the Revolution.

Pennsylvania.—The territory of Pennsylvania, originally disputed between the Swedes, Dutch, and English, was finally granted to William Penn as unoccupied land in 1681, though the Swedes had already made settlements. Penn purchased of the Duke of York the territory of Delaware. Pennsylvania became a State at the Revolution.

Delaware was part of the territory of Pennsylvania purchased of the Duke of York, but was by charter from Penn allowed an independent government. Delaware was recognized as a colony and became a State at the Revolution.

Virginia.—The territory of Virginia, derived under charter to the first colony of Virginia, was reduced by her constitution in 1776 by the cession to Maryland, Pennsylvania, and North and South Carolina of their right of property and jurisdiction. Virginia became a State at the Revolution, claiming territory to the Mississippi, north of that relinquished to North Carolina and extending north indefinitely.

Maryland.—The territory of Maryland, although embraced in the grant to the first colony of Virginia, was, in 1632, granted to Lord Baltimore, and in 1776 relinquished by Virginia. Maryland was recognized as an independent colony and became a State at the Revolution.

West Virginia was formed of western counties of Virginia that did not follow that State in seceding from the Union, and was admitted as a State December 31, 1862.

Kentucky, originally part of Virginia, was claimed by the settlers to be independent, though such claim

was denied by Virginia. The constitution of Virginia of 1776 asserted jurisdiction over that territory, but such jurisdiction was not actually exercised. Virginia assented to a separate government for Kentucky in December, 1789, and by act of Congress in May, 1790, a temporary government was provided for such territory, designated as "south of the Ohio," and in 1790 Kentucky was admitted as a State.

Ohio was formed from the territory north-west of the Ohio that was ceded by an act of Virginia, passed in 1783, being part of the territory derived under the Virginia charters and granted by deed in 1784. At first, on behalf of France, and afterwards of Great Britain, a claim was made to this territory as part of the Province of Quebec, but this claim was extinguished by the treaty of peace with Great Britain in 1783. The North-west Territory, as ceded by Virginia, was organized by Congress in 1787. As this action tended to extinguish claims reserved to Virginia by the deed of cession, the ratification of that State was obtained in 1788. In 1800 Congress divided the North-west Territory into two parts, the easterly part embracing the territory of Ohio and part of that of Michigan, and erected the western part into Indiana Territory. In 1802 Ohio was admitted as a State with boundaries that excluded the territory embraced in Michigan.

Indiana was formed from Indiana Territory, which was divided in 1809, and the westerly part set apart and organized as Illinois Territory. Indiana was admitted as a State in 1816 with boundaries excluding the territory embraced in Michigan.

Illinois was formed from Illinois Territory, which had been set apart from Indiana Territory by act of 1809, from which it received separate territorial organization and was admitted as a State in 1818, with boundaries that excluded the territory embraced in Wisconsin and that west of the Mississippi.

Michigan, established as a Territory in 1805, embraced territory excluded by the northern boundaries of Ohio and Indiana, and in 1818 was extended to the Mississippi, and in 1834 to the Missouri River. Michigan had been claimed as part of the Province of Quebec. (See above under *Ohio*.) Michigan was admitted as a State in 1837 upon assenting to conditions fixed by Congress in 1836, excluding from its boundaries the territory west of the east line of Wisconsin.

Wisconsin.—In 1836, when Congress excluded from Michigan the territory west of Lake Michigan and a line connecting that lake with Lake Superior, it erected such excluded territory into the Territory of Wisconsin, extending to the Missouri and White Earth Rivers. In 1838 that part of the Wisconsin Territory west of the Mississippi was set apart and organized as the Territory of Iowa. Wisconsin was admitted as a State in 1846.

Minnesota.—The Territory of Minnesota was partly derived from the Virginia cession of the North-west Territory and partly under the Louisiana purchase. It was embraced in the Territory of Iowa, established in 1838 upon the division of Wisconsin Territory. It was organized as the Territory of Minnesota in 1849, excluding from its boundaries the Territory of Iowa and that of Dakota and admitted as a State in 1857.

North Carolina.—In 1663 a charter of the Province of Carolina was given, embracing part of the territory conveyed to the first Virginia colony, with boundaries that were extended by charter of 1665 so as to include from about latitude 36° 30' to Florida, and westerly to the South Sea. North Carolina, originally under the government of the Lords Proprietors, became independent as a colony and a State at the Revolution.

South Carolina, originally embraced in the Province of Carolina, received a separate government by the appointment by the Lords Proprietors of William Sayles as governor of that part of the Province of

Carolina south of Cape Carteret. The provincial assembly of South Carolina claimed independence of the Lords Proprietors in 1719. South Carolina became a State at the Revolution.

Georgia, originally part of the Province of Carolina, received a corporate government in 1732, with a cession of that part of South Carolina south of the Savannah River and extending west to the South Sea. A regular colonial government was given in 1752 and Georgia became a State at the Revolution. The constitution of that State in 1798 gave authority for the cession to the United States of the territory west of the Chattahoochee, and that cession was made. The territory thus relinquished was included in the Territory of Mississippi established in 1798 that extended to the Mississippi River.

Alabama was established as a Territory in 1817 out of the Territory of Mississippi, and was admitted as a State in 1819.

Mississippi, organized as a Territory in 1798, was admitted in 1817, comprising that portion of the territory excluded from the limits of Alabama. Portions of the States of Georgia, Alabama, and Mississippi were derived by the cession of the Floridas by Spain.

Tennessee was, upon its cession by North Carolina, embraced in the limits of the territorial government of the territory south of the Ohio, established in 1790, and remained in that condition after Kentucky, part of that territory, was a State. It was admitted as a State in 1796.

Louisiana occupies territory that was part of the Province of Louisiana held by France and ceded by France to the United States by treaty in 1803, during the administration of Pres. Jefferson, for which the United States paid \$11,250,000 in a 6 per cent. stock redeemable in annual payments of \$3,000,000, commencing in fifteen years from the treaty. Under an act of Congress in 1803 possession was taken of this province and its government committed for the time being to the President. In 1804 the province was divided into two Territories, that portion south of latitude 33° being named the Territory of Orleans, and the northerly part being called the District of Louisiana. The Territory of Orleans was organized in 1804 and the District of Louisiana provisionally attached to the Territory of Indiana. In 1805 the District of Louisiana was separately organized as the Territory of Louisiana. Louisiana was admitted as a State in 1811, embracing the Territory of Orleans.

Missouri.—The name of the Territory of Louisiana was in 1812 changed to that of Missouri Territory, and territorial organization completed. In 1820 Missouri was enabled to be admitted to the Union subject to the ratification of the boundaries assigned, and accepted such boundaries, excluding the north part of the Territory of Missouri and that embraced in Arkansas Territory.

Arkansas was organized in 1819 as Arkansas Territory out of that portion of Missouri Territory south of the territory of the present State of Missouri, and was admitted as a State in 1836.

Iowa originally formed part of Missouri Territory, but was separated from that Territory in 1834 and made part of Michigan Territory, and in 1836 embraced in the Territory of Wisconsin. In 1838 it was erected into the Territory of Iowa, and in 1845 was admitted as a State.

Florida.—The territory occupied by Florida was part of that ceded by Spain to the United States by treaty in 1819 under the name of the colonies of East and West Florida, and was organized as the Territory of Florida in 1822, and Florida was admitted as a State in 1845.

Texas was formerly part of the Republic of Mexico and united with Coahuila as a State of that republic. In 1833 Texas declared her independence, as a State of the Mexican Republic, and in 1835 framed a constitution. In 1836 Texas declared her entire inde-

pendence of Mexico and in the same year framed a constitution in conformity with such declaration. This independence was recognized by the United States and other nations. In 1845 Texas was annexed to the United States under a joint resolution of Congress accepted by that State, and in the same year was admitted into the Union.

Kansas.—The territory of Kansas was in part derived from Missouri Territory and in part under the cession of Florida in 1819, and was erected into the Territory of Kansas in 1854, the northerly portion extending to the Rocky Mountains. Kansas adopted a constitution in 1859 excluding the territory occupied by Colorado from its boundaries, and was admitted as a State.

Nebraska.—The Territory of Nebraska was organized in 1854 by the same act that organized the Territory of Kansas, and included with the territory of the present State a portion of that of Colorado, Montana, Dakota, and Wyoming, which were excluded from her boundaries at her admission as a State in 1867.

Colorado.—The territory occupied by Colorado was derived in part from the Territory of Nebraska and in part from that of Kansas, and was organized as the Territory of Colorado in 1861. Colorado was admitted as a State under an act of 1875.

California was occupied by military and naval forces of the United States during the Mexican war, and at its close, in 1848, passed by treaty into possession. It was admitted as a State in 1850.

New Mexico and *Utah* were organized as Territories in 1850 from lands derived from Mexico under the treaty of peace in 1848. New Mexico was enlarged by the Gadsden purchase from Mexico in 1853. *Nevada* was separated from Utah and made a Territory in 1861, and was admitted as a State in 1864. *Arizona* was separated from New Mexico and organized as a Territory in 1863.

Montana, *Wyoming*, and *Dakota* were, in 1854, embraced in the Territory of Kansas, that Territory being in part derived from the Louisiana purchase, in part through the treaty of peace with Mexico, and in part through the annexation of Texas. Montana was organized as a Territory in 1864, Dakota in 1861, and Wyoming in 1868.

Washington Territory was organized in 1853 of land derived under the treaty of 1846 with Great Britain for the settlement of the North-west boundary, and was originally established as the Territory of Oregon in 1846, and, upon the admission of Oregon as a State in 1859, received the residue of Oregon Territory not included in that State. *Idaho* was separated from the Territory of Washington and organized as a Territory in 1863.

The *Indian Territory* was acquired by the annexation of Texas, and was set apart for Indian occupation in 1828, under treaties with certain Indian tribes, and has not been organized as a Territory of the United States.

Alaska was acquired by purchase from the Russian government in 1867, and has not yet received complete territorial organization. After long remaining under military control, it was made a District in 1884, and has a governor appointed by the President.

The District of *Columbia* was ceded to the United States by Virginia and Maryland in 1791 as the national seat of government. Virginia's share was retroceded in 1846. From 1871 to 1874 the District had a territorial form of government, but this was revoked by Congress.

The authority possessed by Congress over the Territories is sovereign, and without other limitation than such as is imposed by the Constitution upon its powers at large. Article IV. of the Constitution declares that "Congress shall have power to dispose of and make rules and regulations respecting the territory or other property belonging to the United States." This power has been judicially defined as sovereign in its

nature. Although the Articles of Confederation are silent as to the authority of Congress over the Territories, yet the Congress under those articles in 1787 conferred territorial government on the "Territories north-west of the Ohio," which had been ceded to the Union by Virginia, and that authority was recognized and confirmed by the first Congress under the Constitution.

The authority of Congress to acquire territory from foreign states was seriously doubted by Mr. Jefferson, yet was exercised during his presidency in the purchase of Louisiana from France. The purchase of Florida from Spain and of Alaska from Russia, and the acquisition of the western part of the continent by the treaty of peace with Mexico at the close of the Mexican war, are instances showing the full recognition of the sovereign authority of Congress over the Territories of the United States.

The territorial government established in 1787 over the "Territory north-west of the Ohio" was a precedent and model that gave definition to the territorial policy of the United States. The form of government established in that Territory was substantially adopted in the succeeding organization of Territories down to the organization of Missouri Territory in 1812; it provided for the appointment of a governor, secretary, and judges of the Territory, with full legislative, executive, and judicial authority, subject to the Constitution and laws of the United States, but with a contingent provision for the creation of a legislative body when the population of the Territory should be such as to demand it. Another feature of the organic law of the "Territory north-west of the Ohio" which has exercised a large influence over the territorial policy was the proviso in that law that slavery should never exist in that Territory. This was intended as an organic provision that should enter into the constitutions and laws of all the States formed out of this Territory and form part of the organic law of such States, and that effect has been realized and its validity judicially recognized.

The organization of the Territory of Missouri under the act of 1812, while still retaining in the President of the United States the appointment of executive and judicial officers, provided for a legislative authority largely popular in its nature, but to some extent dependent upon the national authority. The legislative power was vested in a general assembly, that should consist of the governor, a legislative council, and a house of representatives. The house of representatives was filled by popular election, but the legislative council was selected by the President of the United States from a larger number of persons chosen by the representatives, and could be removed at the pleasure of the President. All laws were required to have not only the consent of the legislative council but that of the governor. All territorial laws depended for their efficacy upon their consistency with the Constitution and laws of the United States.

In 1816 the provisions of the organic act as to the choice of the legislative council were changed so as to make that body subject to popular election. The territorial act of Missouri contains a Bill of Rights similar to those generally introduced into the State constitutions.

Upon the admission of Missouri as a State of the Union the policy of excluding slavery from a portion of the Territories of the United States which was inaugurated by the act constituting the Territory North-west of the Ohio, was extended over the territory acquired from France under the name of Louisiana, which lay north of latitude 36° 30', and was intended as an organic provision that should extend to all Territories and States organized from that territory. (See SLAVERY.) (A. J. W.)

TERRY, ALFRED HOWE, major-general, was born at Hartford, Conn., Nov. 10, 1827. He was educated at Yale College, and was admitted to the bar in 1848.

He was made clerk of the New Haven county court in 1854, and was active in the militia. During the Crimean war he visited Europe in order to observe military operations, and at the outbreak of the American civil war he was probably better informed on such subjects than any other American outside of the regular army. The time came when his knowledge was to be reduced to practice. In 1861 he led his company to Washington, and at the battle of Bull Run he covered the retreat and saved a large amount of government property. He then raised the Seventh Connecticut regiment, and with it participated in Gen. T. W. Sherman's expedition to the Georgia coast. He was engaged in the siege of Fort Pulaski and afterwards had command of it and other forts. In March, 1862, he was commissioned brigadier-general and led a brigade at the battle of Pocotaligo. In 1863 he had command of a division and was engaged in operations in Charleston Harbor. He was afterwards with Gen. Butler's Army of the James and took part in the action at Drury's Bluff. From May till December, 1864, he commanded the Tenth Army Corps. In January, 1865, he commanded the land forces in the expedition against Fort Fisher, at the mouth of Cape Fear River. The fort was captured by assault Jan. 15, and from that date ran his commissions as major-general of volunteers and brigadier-general U. S. A. Gen. Terry marched inland and joined with Gen. Sherman in the closing events of the war. He afterwards had command.

TEWFIK PACHA, MOHAMMED, Khedive of Egypt, was born Nov. 10, 1852, at Cairo. He is the eldest son of Ismail Pacha, and when his father was compelled to abdicate, Aug. 8, 1879, he succeeded to the throne. The principal events of his reign have been narrated under Arabi Pacha (q. v.).

THANKSGIVING, in the United States, denotes an annual festival, not instituted to celebrate a single event, but to show proper gratitude to God for the blessings of the closing year. It was meant to gather up in thought all the mercies of a twelvemonth, all the bounties of the harvest, all the manifold gifts of Providence, and show a fitting recognition of the whole in gratitude which should overflow in festivity and mirth. As now observed, it may be said to be borrowed from the Jewish Feast of Tabernacles. The Hebrews, under the Mosaic law, celebrated the goodness of God in a harvest festival, under branches of trees and in tents of palm. They felt, beyond any other ancient people, that the fruits of the earth, the things needed for sustenance and comfort and cheer, were gifts of divine beneficence; and that it was fitting to express gratitude for them in a public celebration in which the gifts should be enjoyed. Thanksgiving day differs in these respects from the religious festivals, or holy days, that have prevailed in the various Christian churches. There have, however, been national and local festivals which have a closer resemblance. In Holland the anniversary of the deliverance of the city of Leyden from the siege, Oct. 3, 1575, was kept as a religious festival of thanksgiving and praise. In the English Church service the Fifth of November is celebrated in commemoration of the discovery of the Gunpowder Plot. The German Protestants, Lutheran and Reformed, have the custom of "Harvest Home," with religious services as well as general feasting and rejoicing. This custom was brought by German and Dutch immigrants into the United States. Hence probably came the local Thanksgiving day in parts of Long Island, after driving home for the winter the cattle which, during the most of the year, were pastured at Montauk Point.

But the American custom of Thanksgiving is historically traced beyond question to the earliest settlers of New England. In 1621, within a year after the landing of the Pilgrims at Plymouth, Gov. Bradford wrote as follows: "They begane now to gather in the small harvest they had, and to fitte up their houses

and dwellings against winter, being all well recovered in health and strength, and had all things in good plenty; for as some were thus employed in affairs abroad, others were exercised in fishing about codd, and bass, and other fish of which they took good store, of which every family had their portion. All the summer there was no waste. And now began to come in store of fowle, as winter approached, of which this place did abound when they came first (but afterwards decreased by degrees) and beside water fowle there was great store of wild turkies of which they took many, beside venison, etc. Beside they had about a peck of meal a weeke to a person, or now, since harvest, Indian corn to that proportion." In this connection Edward Winslow described the public commemoration in the following manner: "Our harvest being gotten in, our Governor (William Bradford) sent four men on fowling, so that we might after a special manner rejoice together after we had gathered the fruit of our labors. They four in one day killed as much fowl as, with a little help beside, served the company almost a week. At which time, amongst other recreation we exercised our arms, many of the Indians coming among us, and among the rest their greatest king Massasoit, with some 90 men, whom for three days we entertained and feasted; and they went out and killed 5 deer, which they brought to the plantation and bestowed on our Governor, and upon the Captain (Myles Standish) and others. And although it be not always so plentiful as it was at this time with us, yet by the goodness of God, we are so far from want that we often wish you partakers of our plenty." The next Thanksgiving day was in July, 1623. A long and severe drought had prevailed, and the governor appointed a day of fasting and prayer. During the prayer "soft, sweet, and moderate showers" fell, continuing for two weeks. The fasting and praying were changed into devout thanksgiving.

In the Plymouth colony Thanksgiving days were appointed for 1651, 1668, and 1680, and in the Massachusetts Bay colony similar observances were held in 1633, 1634, 1637, 1638, and 1639. The colony and province of New York was not without its days of praise and prayer. The Dutch governors proclaimed such days in 1644, 1645, 1655, and 1664. The English governors followed the example of their predecessors in 1760 and in 1775. Throughout the Revolution Congress annually recommended days of Thanksgiving. In 1784 there was a day of general praise for the return of peace and liberty to the country. In 1789 Pres. Washington appointed a day of rejoicing for the adoption of the Constitution. In 1795 he issued a call for a national thanksgiving; the preamble was this: "When we review the calamities that afflict so many other nations, the present condition of the United States affords much matter of consolation and satisfaction. Our exemption hitherto from foreign war; an increasing prospect of the continuance of that exemption—the great degree of internal tranquility we have enjoyed—the recent confirmation of that tranquility by the suppression of an insurrection which so wantonly threatened it—the happy course of our public affairs in general—the unexampled prosperity of all classes of our citizens—are circumstances which peculiarly mark our situation with indication of the divine beneficence toward us. In such a state of things it is in an especial manner our duty as a people, with reverence and affectionate gratitude, to acknowledge our many and great obligations to Almighty God, and to implore him to continue and confirm the blessings we experience." On account of these reasons the President recommended "to all religious societies and denominations and to all persons whomsoever, within the United States, to set apart and observe Thursday, the 19th day of February next, as a day of public thanksgiving and prayer, and on that day to meet together and render sincere and hearty thanks to the great Ruler of nations for the manifold and signal

mercies which distinguish our lot as a nation—particularly for the possession of constitutions of government which unite, and by their union establish, liberty with order; for the preservation of our peace, foreign and domestic; for the reasonable control which has been given to a spirit of disorder in the suppression of the late insurrection, and generally for the prosperous condition of our affairs, public and private; and at the same time, humbly and fervently to beseech the kind Author of these blessings graciously to prolong them to us; to imprint on our hearts a deep and solemn sense of our obligations to Him for them; to teach us rightly to estimate their immense value; to preserve us from the arrogance of prosperity and from hazarding the advantages we enjoy by delusive pursuits; to dispose us to merit the continuance of his favors by not abusing them, by our gratitude for them, and by a corresponding conduct as citizens and as men; to render this country more and more a propitious asylum for the unfortunate of other countries, to extend among us true and useful knowledge, to diffuse and establish habits of sobriety, order, morality, and piety, and finally to impart all the blessings we possess or ask for ourselves to the whole family of mankind." This proclamation followed the precedent by which Thursday had been uniformly designated by the governors of the New England States as the day of thanksgiving. In those States the Congregational Church predominated. In 1789 the Prayer-book of the Protestant Episcopal Church recognized the authority of the civil government to appoint such a feast. The custom went gradually to other States. In 1795 Gov. Jay, of New York, issued a proclamation of thanksgiving, which was but slightly attended to. A second trial was made by Gov. De Witt Clinton in 1817 and a hearty response was made. Since 1817 the annual Thanksgiving has been celebrated in the State of New York with hardly a break. The State of Pennsylvania followed soon afterward; but the Western States were more slow in adopting the custom. Illinois, admitted as a State in 1818, did not appoint a day of Thanksgiving until 1840, the day named being in December. The Southern States, owing to difference of climate and institutions, did not take kindly to the custom which had originated in New England; yet in 1858 the governors of eight Southern States sent forth proclamations for days of thanksgiving.

Until the great national crisis of the civil war, with the exception of Washington's administration, the custom was strictly confined to the will of the governors of the respective States. During the civil war Pres. Lincoln frequently appointed special days of thanksgiving for national victories; and more than once, when the results of great battles were discouraging to the Union cause, he appointed days of fasting and prayer. In 1863 he issued a long proclamation, appointing the last Thursday of November as a day of thanksgiving and prayer. The closing part of this document was in these words: "I recommend to the people of the United States that, while offering up the ascriptions justly due to God for such singular deliverances and blessings, they do also, with humble penitence for our national perverseness and disobedience, commend to his tender care all those who have become widows, orphans, mourners, or sufferers in the lamentable civil strife in which we are unavoidably engaged; and fervently implore the interposition of the Almighty hand to heal the wounds of the nation and to restore it, as soon as may be consistent with the divine purposes, to the full enjoyment of peace, harmony, tranquility, and union." Since that year every President of the United States has appointed the last Thursday of November as a national day of thanksgiving, and nearly all the governors of the States have followed with proclamations for their respective States.

In the Protestant churches the religious observance of Thanksgiving is provided for by the several congregations and their ministers or other officers. Seldom

has any objection been made to the civil government appointing a day for religious worship, though some theologians, who have discussed the question, have insisted that the civil authorities can only recommend a day for the purpose, but cannot invade the religious rights of the people by enforcing its observance. This conclusion coincides with the view of the civil courts from the other side, and, indeed, with the general American idea of the relations of the state to religion.

In the Roman Catholic Church Thanksgiving day received no official attention until the Plenary Council met at Baltimore in 1885. It was then recommended that extra prayers be offered at the services on that day. Accordingly, in November, 1888, Cardinal Gibbons issued a circular, requesting the clergy of the archdiocese of Baltimore to honor the festival by reciting the prayers for the authorities of the State and nation after the late mass on that day. Similar directions were given by other prelates. This recognition will probably cause a still more general observance of Thanksgiving day, though American citizens of that faith had already in many instances shown regard for the festival.

Thanksgiving days, appointed by the national or State authorities, are a legal holiday in all the States of the Union. (See LEGAL HOLIDAYS.) (F. O. M.)

THAXTER, CELIA, poet, was born at Portsmouth, N. H., June 29, 1835. Since her fifth year she has lived on Appledore, one of the Isles of Shoals, about 9 miles off the coast. Her maiden-name was Leighton, and she was married at the age of sixteen. In 1867 she wrote for the *Atlantic Monthly* some essays on her island-home, which were gathered in a volume—*Among the Isles of Shoals* (1873). Her poems, collected from magazines and newspapers, are full of the charm and mystery of the sea.

THAYENDANEGEA. See BRANT, JOSEPH.

THAYER, SYLVANUS (1785–1872), called "Father of the Military Academy" at West Point, was born at Braintree, Mass., June 19, 1785. He graduated at Dartmouth College in 1807, and at West Point in 1808. He was employed in the construction of coast defences until 1812, when he was made chief-engineer of the Northern army for the invasion of Canada. In 1815 he was sent to Europe to examine the military schools, and on his return was made superintendent at West Point. The whole system of training there used was formed by Major Thayer. (See MILITARY ACADEMIES.) In 1833 he was employed in constructing forts in Boston harbor, and in 1838 became president of the Board of Engineers for coast defence. In 1843 he went to Europe for professional purposes, and after his return continued his work of coast defence until 1857, when he was relieved of duty, though not formally retired until 1863. He published some professional papers and gave liberally to the cause of education. Dartmouth College and his native town were among his beneficiaries.

THEATRE. See DRAMA.

THEOLOGICAL SEMINARIES IN THE UNITED STATES.—During the colonial period, and in the early years of the republic, preparation for the ministry, as for the other professions, was obtained largely from private sources, according to location and opportunity. Harvard was designed as a seminary for preachers, and a chair of divinity was founded there in 1721. Theological classes were held at Yale from 1754. The few institutions of learning had this end more or less in view, for a far larger proportion of students became ministers than now; but many sought instruction at home or from the nearest clergyman. The first Protestant theological school was initiated by the Associate Presbyterian Synod in Beaver co., Pa., in 1794, under John Anderson, D. D. The Associate Reformed Seminary, in New York city, was begun 1804 under John M. Mason, D. D. Andover, New Brunswick, and Princeton followed within the next eight years, and there are now over 150 institutions of

the kind, which may best be grouped here under the heads of the several religious denominations. The statistics are taken chiefly from the last report of the U. S. Commissioner of Education (for 1885–86), and many facts have been gathered from the *Schaff-Herzog Encyclopaedia*. These schools represent every degree of strength, from a merely or nearly nominal existence to a long record of wide usefulness. Many of them stand on their own independent foundation; several of the greatest and some of the least are departments of universities or colleges. In the latter case the figures reported in a few instances appear to indicate the whole number of students in the college, not that in the theological department. The period of study in all the seminaries of higher character is 3 years, and the classes are usually called senior, middle, and junior. The States most extensively provided with these institutions will be found to be Pennsylvania and Illinois, each having 17; the denominations which claim the largest number of schools and instructors are the Roman Catholic and Baptist.

BAPTIST.

Hamilton Theological Seminary, located in the village of Hamilton, N. Y., was chartered 1819 and organized 1820. As the oldest Baptist seminary in America, it has been vitally identified with the history of the body for two-thirds of a century, and has furnished a large proportion of its ministers. It has a good endowment, 130 acres of land, three school buildings, and several residences. The successive presidents have been Drs. D. Hascall, N. Kendrick, J. S. Maginnis, G. W. Eaton, and E. Dodge. There are 6 chairs, 5 of which are now filled. Among their occupants have been Barnas Sears, T. J. Conant, A. C. Kendrick, and other eminent men. The seminary had at last accounts 54 students and 18,000 volumes in the library.

Newton Theological Institution, at Newton Centre, Mass., was organized 1825 and chartered 1826. The plan was to provide college graduates with a 3-years' course in divinity, beginning with the Hebrew and Greek Scriptures and giving prominence to Biblical studies. This limitation has been relaxed sufficiently to admit non-graduates who could follow the subjects pursued, and even to indulge a few with a 2-years' course in English alone. The institution was opened 1825, with Ira Chase, D. D., as sole teacher. H. J. Ripley, D. D., was appointed the next year; J. D. Knowles in 1834 (he died 1838); B. Sears, D. D., 1836, and H. B. Hackett, D. D., 1839. From that date there were 4 professors, to whom an instructor in Hebrew was added 1846. From 1868 there were 5 professors and a teacher of elocution. There are now 8 instructors and 68 students. Alvah Hovey, D. D., LL. D., is president and professor of theology, H. Lincoln, D. D., professor of church history, and O. S. Stearns, D. D., of Old Testament Biblical interpretation. The library has 18,500 volumes. The endowment is over \$300,000, and the value of grounds and buildings about \$130,000. There are three halls, Colby, Farwell, and Sturtevant, with a gymnasium and 25 or more scholarships. Newton has sent forth full a thousand ministers, including some 70 foreign missionaries. It is governed by a board of 48 trustees, clerical and lay.

Shurtleff College, at Upper Alton, Ill., opened 1827 and chartered 1832, has a theological department under A. A. Kendrick, D. D., with 3 instructors, 13 students, and a library of some 7500 volumes.

Rochester Theological Seminary, at Rochester, N. Y., was chartered 1850 and opened 1851 with two professors. E. G. Robinson, D. D., LL. D., now president of Brown University, was long its leading spirit. Drs. T. J. Conant, H. B. Hackett, and A. C. Kendrick held chairs. A. Strong, D. D., has been president since 1872. There are now 10 instructors, among them Drs. Howard Osgood and W. A. Stevens, and

full a hundred students. The German department was founded in 1854. Near a thousand have entered from all parts of America, about one-fourth being Germans. The seminary has nearly \$500,000 of invested funds, and grounds and buildings valued at \$123,000. Trevor Hall was erected 1869 and Rockefeller Hall 1879. The library has over 21,000 volumes, and includes that of Neander. No subscription to creeds or formal statement of doctrine is here required, but any members of evangelical bodies are admitted on evidence of religious experience and a call to the ministry.

The Southern Baptist Theological Seminary was organized 1859 at Greenville, S. C., chartered 1876, and removed 1877 to Louisville, Ky. Its first endowment was destroyed by the civil war, and its operations suspended from 1862 to 1865, when it started again with 7 students. It has now some 114, with 6 teachers, real estate worth \$120,000, over \$200,000 of invested funds, and a library of 8500 volumes. The varying wants of students are met by a full theological course, one limited to the vernacular and elective studies; diplomas are given accordingly. J. P. Boyce, D. D., LL. D. (d. 1889), was chairman of the faculty and had been a professor since 1859. B. Manly, D. D., and J. A. Broadus, D. D., were also appointed at the opening of the seminary; C. H. Toy, D. D., 1869 (now of Harvard University); W. H. Whitsett, D. D., 1872, and G. W. Riggan, 1881.

Wayland Seminary, founded 1865 at Washington, D. C., under the care of G. M. P. King, has real estate worth \$45,000 and a library of 2000 volumes. It reports 6 teachers and 126 students, but the number taking a theological course is probably much smaller, having been given a few years earlier as 3.

Shaw University, at Raleigh, N. C., organized 1865, chartered 1874, has a theological department under H. M. Tupper, D. D., with 2 instructors and 40 students.

Roger Williams University, at Nashville, Tenn. (formerly Nashville Normal and Theological Institute), opened 1865, reports a theological department under D. W. Phillips, D. D., with 2 instructors and 35 students.

The Baptist Union Theological Seminary, at Morgan Park, Ill., was opened in 1866, under the auspices of the Chicago Baptist Union, in the building of the Chicago University, by N. Colver, D. D., and J. C. C. Clark, who taught some 12 students there. A full organization was effected in October, 1867, with 20 students, under G. W. Northrup, D. D., as president and professor of systematic theology, and J. B. Jackson, D. D., as professor of church history. A building was erected in Chicago 1869. A Scandinavian department, under J. A. Edgren, began 1873 with 4 students; since increased to 28. The seminary was removed 1877 to Morgan Park, where it has 5 acres and a building worth \$50,000. A fair endowment was raised 1881 and subsequently. There are now 7 instructors, 90 students, and 18,000 volumes in the library. Dr. Northrup is still president.

The Atlanta Baptist Seminary, opened 1867 at Atlanta, Ga., is ruled by S. Graves, D. D., has real estate worth \$15,000, a library of 2500 volumes, and reports 5 teachers and 152 students, but not all in theology.

Richmond Theological Seminary (formerly Richmond Institute) was organized 1867 at Richmond, Va., and chartered 1876. C. H. Corey, D. D., is its head. It has 4 instructors, 50 students, a library of 3200 volumes, and real estate valued at \$20,000.

Crozer Theological Seminary, at Upland, Delaware co., Pa., was chartered 1867, and opened 1868 with 20 students. It now has 560 under 6 professors, H. G. Weston, D. D., being president from the start, a library of 9000 volumes, a lecture fund, and a fair endowment. There are two courses of study with differing diplomas.

William Jewell College, at Liberty, Mo., founded

1868, has, or had, a Jeremiah Vardeman School of Theology, pronounced by the commissioner of education "not a theological seminary proper."

The Benedict Institute, at Columbia, S. C., opened 1871, reports 6 teachers, 35 pupils, and a library of 1500 volumes. C. E. Becker is at its head.

Jackson College, opened 1877 at Jackson, Miss., has 6 teachers, 30 pupils, and real estate worth \$30,000. This is doubtfully placed among the theological seminaries.

Indian University, at Muskogee, Ind. Terr., founded 1880, has a theological department under A. C. Bacani, reporting 6 teachers, 70 students, and real estate worth \$28,000. These figures perhaps belong to the whole university.

The Selma University (formerly Alabama Baptist Normal and Theological Institute) was organized 1877, and opened 1878 at Selma, Ala. C. L. Pierce is at its head. It reports real estate worth \$15,000, with 7 teachers and 170 students, probably not all theological.

Bishop College, at Marshall, Tex., opened 1881, has a theological department under S. W. Culver, which reports 7 teachers and 166 pupils, with real estate valued at \$55,000. Here again the figures probably belong to the whole college.

Leland University, at New Orleans, La., has a theological department under H. R. Traver, with 3 instructors and 34 students.

Mercer University, at Macon, Ga., reports a theological department, with three students, under J. G. Ryal, D. D.

FREE-WILL BAPTISTS.

Hillsdale College, at Hillsdale, Mich., chartered 1852, opened 1855, has a theological department under G. F. Mosher, with 9 instructors, 53 students, and a library of 3000 volumes.

Bates College Theological Seminary, at Lewiston, Me., opened 1870, reports 4 teachers, 29 students, and 3000 volumes. O. B. Cheney, D. D., is at its head.

CHRISTIAN (*Disciples of Christ*, q. v.).

Eureka College, Eureka, Ill., chartered 1855, opened 1864, has a Bible department, with 3 teachers, 30 students, and a library of 2000 volumes.

Oskaloosa College, Oskaloosa, Ia., chartered 1856, opened 1872, has a Bible department, with 2 teachers, 13 students, and 2000 volumes.

The Christian Biblical Institute, at Standfordville, N. Y., opened 1869, reports 5 teachers, 11 pupils, 1900 volumes, and real estate worth \$40,000. J. B. Weston, D. D., is at its head.

The College of the Bible, at Lexington, Ky., chartered 1865, opened 1877, has 3 teachers and 100 pupils under R. Graham.

Drake University, Des Moines, Ia., opened 1881, has a Bible department, with 2 teachers, 48 students, and 1500 volumes.

CHRISTIAN (*Christian Connection*, q. v.).

Union Christian College, at Merom, Ind., opened 1862, has a "Berean department," with 2 teachers and 4 pupils.

A *Christian Biblical Institute* was begun at Eddytown, N. Y., 1869.

A *Literary and Theological Institute* for colored persons was opened at Franklinton, N. C., 1881.

CONGREGATIONAL.

Andover Theological Seminary, at Andover, Mass., was planned 1807, and intended to be connected with Phillips Academy, founded 1778. A junction was effected with another about to be established at Newbury, Mass., the "moderate" and "consistent" Calvinists uniting on the basis of a creed similar to the Westminster Catechisms. The seminary was incorporated as a branch of Phillips Academy under its trustees, but also under the supervision of a board of

visitors. It was opened Sept. 23, 1808, with a sermon by Pres. Dwight, of Yale. Thirty-six students entered at once. Dr. E. Pearson was the first professor of sacred literature, 1808-9; Dr. L. Woods of Christian theology, 1808-46; Dr. E. D. Griffin of sacred rhetoric, and Dr. Jas. Murdock of ecclesiastical history. Rev. Moses Stuart was professor of sacred literature, 1809-47, and was then succeeded by Dr. B. B. Edwards. Dr. E. Robinson was professor extraordinary in this branch 1830-33. Drs. E. Porter, R. Emerson, and T. H. Skinner were also in the faculty. Dr. E. A. Park was professor of sacred rhetoric 1836-47, and of theology 1847-81. Dr. A. Phelps succeeding to his former chair 1848-79; both these are now professors emeritus. In addition to the first 5 chairs, others of the relations of Christianity to science, of elocution, and of Biblical theology have been founded. There have been many gifts and benefactors. The buildings are 2 dormitories, 2 chapels, a library with over 45,000 volumes, a gymnasium, 8 houses for professors, etc. The real estate is valued at \$107,000; but it is not of material things that Andover is proud. During 80 years some 3000 students have been instructed here, and here the American Education Society, the Tract Society, the Temperance Society, and the oldest religious newspaper in America had their origin. The Andover Press has published the works of Profs. Porter, Woods, and Stuart, besides many commentaries, lexicons, etc. The *Biblical Repository* was printed here 1831-38, and the *Bibliotheca Sacra* founded 1844. The place has been a famous centre of religious learning and research. Andover theology professed to be a compromise between extreme Calvinism and Hopkinsianism, incorporating the substance of both. This is represented by the seminary "creed."

During the last few years an unfortunate controversy has threatened the credit and usefulness of this venerable institution. On Dr. Park's withdrawal in 1881 Dr. Newman Smyth was elected to his chair by the trustees. The Board of Visitors did not concur, and he was not installed. A question was afterwards raised and much mooted as to the orthodoxy of the faculty, in view of essays on "Progressive Orthodoxy" in the *Andover Review*, and especially of certain expressions as to the "last things." The chairs are now held by Drs. J. P. Gulliver, E. C. Smyth, W. J. Tucker, J. P. Taylor, J. W. Churchill, G. Harris, E. Y. Hincks, W. H. Ryder, and G. F. Moore. Drs. S. Harris, E. A. Lawrence, and E. B. Andrews are lecturers. The number of students for the year 1887-88 was 50; it is now larger. Dr. E. C. Smyth is president of the faculty. There are 2 fellowships and 30 scholarships. A fourth year is allowed for advanced study.

Bangor Theological Seminary was chartered 1814, and opened at Hampden, on the Penobscot (then in Massachusetts) October, 1816. In 1819 it was removed to Bangor. In 1820 the State of Maine was created, and the first class in this seminary graduated, numbering 6. The course was at first designed for such as had not gone through college and covered 4 years. The classical or preparatory department was abandoned in 1827, and the curriculum made to correspond with those of similar institutions, embracing 3 years of purely theological study. J. Ashmun, G. Shepard, and L. Woods, Jr., were among the professors. Dr. Enoch Pond (q. v.) was professor of theology 1832-56, and professor of ecclesiastical history 1856-70, also holding the presidency 1856-82. He was succeeded by L. J. Paine, D. D. There are now 5 professors, 30 students, with a library of 15,000 volumes, and real estate valued at \$65,000. Nearly 700 ministers have been sent forth with thorough theological preparation, and near 200 have received a partial training.

Yale College (now Yale University), New Haven, Conn., from its beginning in 1701-2 had a view to education for the ministry, and a professor of divinity

was the first appointed (1755) after the rector. Many of the most eminent clergy of America were trained here, as Edwards, Hopkins, Emmons, Bellamy, Dwight, Backus, Moses Stuart, N. W. Taylor, Lyman Beecher, Bennet Tyler, and E. Robinson. The theological school as a distinct department was established 1822, with N. W. Taylor, E. T. Fitch, and J. W. Gibbs as professors, to whom C. A. Goodrich was added 1839. The faculty now consists of Pres. Dwight and Dr. G. H. Day, Hebrew language and literature and Biblical theology (Old Testament); S. Harris, systematic theology; G. P. Fisher, ecclesiastical history; L. O. Brastow, homiletics and the pastoral charge; J. E. Russell, Biblical theology (New Testament); and G. B. Stevens, New Testament criticism and interpretation. There are also 3 instructors and 5 special lecturers. In 1886-87 there were 108 students, 10 of whom were pursuing graduate or fourth-year studies. The school has a reference library of 3000 volumes, and the library of church music of the late Dr. Lowell Mason.

The Theological Institute of Connecticut, otherwise Hartford Theological Seminary, was opened May 13, 1834, at East Windsor Hill, Conn., with Dr. Bennet Tyler as president. He led and formulated the severer New England theology, as against the liberalizing tendencies of Dr. N. W. Taylor, who was all-powerful at New Haven. Between these was much controversy, and their differences, then widely supposed to affect matters of faith, led to the formation of the Pastoral Union of Connecticut in 1833, and of its Theological Institute Dr. Tyler retained the presidency till 1857. The first professors with him were Drs. J. Cogswell, 1834-44, and W. Thompson, 1834-81. There are now 5 professors, 2 instructors, and some 40 students. In 1865 the institute removed to Hartford, where Hosmer Hall was erected 1879-80. The library contains 42,000 volumes. Near 600 ministers received their training at Hartford.

Oberlin Theological Seminary is a department of the college at Oberlin, O. In 1834 most of the students of Lane Seminary, at Cincinnati, withdrew because anti-slavery discussion was prohibited. They agreed to go to Oberlin if C. G. Finney (q. v.), of New York, would take the chair of theology there, and Arthur Tappan persuaded him to do so, and provided the means. Asa Mahan (q. v.) was elected president, and J. Morgan, of Lane Seminary, professor of New Testament literature. The seminary opened 1835 with 35 students. There are now over 400 alumni, mostly college graduates, and over 50 students in attendance. J. H. Fairchild, D. D., is president and professor of theology. There are 5 more professors and an instructor. These are not required to sign a creed, but the theology taught is new-school Calvinism of the Edwardian type. There is a good building, which cost some \$75,000, and a reference library of 2000 volumes.

The Chicago Theological Seminary was organized and chartered 1854, and opened Oct. 6, 1858, with 29 students and 2 professors, Drs. J. Haven and S. C. Bartlett. It now has 7 professors, 2 instructors, some 65 students, a library of 7500 volumes, and 2 halls facing Union Park, and worth \$127,000. There are two courses of English study and a German department; some 600 students have attended, and half as many graduated.

The Pacific Theological Seminary, at Oakland, Cal., was organized and chartered 1869. J. A. Benton, D. D., is senior professor. It has 3 teachers, 11 students, and 4000 volumes.

Fisk University, at Nashville, Tenn., organized 1869, has or had a theological course under E. M. Cravath.

Strait University, at New Orleans, La., chartered 1869, opened 1870, reports a theological department with 36 students under R. C. Hitchcock.

Talladega College, at Talladega, Ala., chartered 1869, opened 1872, has a theological department with 12 students under G. W. Andrews.

A German Congregational Theological Seminary, at Crete, Neb., opened 1878, has 15 students under W. Sims.

EPISCOPAL.

The General Theological Seminary in New York city was organized by the General Convention May 27, 1817, and opened May 1, 1819, in a room of St. Paul's Chapel, Drs. S. H. Turner and S. F. Jarvis being the first professors. It was removed to New Haven 1820, but brought back to New York in February, 1822, with 6 professors and 23 students, and chartered the same year. It is governed by a Board of Trustees elected by the General and Diocesan Conventions, each bishop being a member *ex officio*. Successive buildings were erected 1825, 1834, and 1883. Its finances have always been well managed, and it now has real estate worth \$600,000 and a library of some 19,000 volumes. Among its professors have been Bishops Brownell, Hobart, B. T. Onderdonk, Whittingham, and Seymour, Drs. Bird Wilson, Ogilby, Haight, S. R. Johnson, Mahan, S. Seabury, and F. Vinton, besides C. C. Moore, LL. D., and Hon. G. C. Verplanck. The faculty now consists of Drs. E. A. Hoffman, dean; W. E. Eigenbrodt, pastoral theology; S. Buel, systematic divinity; R. C. Hall, Hebrew and Greek; A. Oliver, Biblical learning and interpretation of Scripture; W. J. Seabury, ecclesiastical polity and law; T. Richey, ecclesiastical history, and F. T. Russell, instructor in elocution. Several of these chairs have special endowments. An alumni professorship of evidences is not yet filled. There are 88 students. To the buildings on Chelsea Square (Sherred Hall, library and deanery) a chapel was added 1886-8.

The Protestant Episcopal Theological Seminary of Virginia was founded in Alexandria, Va., 1823, Dr. R. Keith being the first professor. In 1827 it was removed to a point over 2 miles west of Alexandria and 7 from Washington. It was not incorporated till 1854. Dr. W. Sparrow was professor of systematic divinity 1841-74. The chair of church history was filled by Drs. Lippitt, 1827-41, and J. May, 1841-61. It now has 6 professors and instructors, Dr. J. Packard being dean, with about 40 students, a library of 12,000 volumes, and several buildings. There is a preparatory department with a two-year course. It has sent forth some 800 ministers and 50 foreign missionaries, among them the late Dr. Hill of Athens, Bishops Payne of Cape Palmas in Africa, Boone of China, and Williams of Japan. Dr. Phillips Brooks of Boston is an alumnus.

The Theological Seminary of the Protestant Episcopal Church in the Diocese of Ohio, otherwise Bexley Hall, at Gambier, Ohio, was chartered 1824 and opened 1825. It has 5 instructors and a library of 7000 volumes, is under the management of Bishop Bedell, and is in relations with Gambier College. F. James, D. D., is senior professor.

Nashotah House, at Nashotah, Wis., opened 1841 and chartered 1847, has sent forth many Western clergy. It is controlled by 7 Western bishops, and has 20 students, a library of 9000 volumes, and real estate valued at \$100,000, but depends for its support on voluntary offerings. G. G. Carter is president, and Drs. W. Adams, J. M. Clarke, and T. M. Riley, professors.

The Berkeley Divinity School, at Middletown, Conn., was at first a department of Trinity College, Hartford, and as such graduated its first class in 1850. It was incorporated 1854 and removed to its present location, where it has a library of 17,000 volumes. Bishop Williams is president, and J. Binney, F. Gardiner, D. D., W. A. Johnson, S. Clarke, and F. T. Russell, professors.

Grinnell College, Davenport, Iowa, chartered 1859, has a small theological department (Lee Hall) under the direction of Bishop Perry. W. H. Barris, D. D., is dean, C. H. Seymour, professor, and C. R. Hale, D. D., instructor.

Seabury Divinity School, at Faribault, Minn., was opened 1860. It is controlled by Bishop Whipple, has 6 teachers, 25 students, a library of 6300 volumes, and real estate worth \$60,000.

The Divinity School of the Protestant Episcopal Church in Philadelphia was organized and chartered in 1862 while the seminary at Alexandria was closed by the war. An informal training-school had existed for some five years previous. An endowment was provided, a library of 8000 volumes, and a building in West Philadelphia, which was exchanged in 1882 for a larger one at Woodland avenue and Fiftieth street. E. T. Bartlett, D. D., is dean, and Drs. G. E. Hare, D. R. Goodwin, J. F. Garrison, and J. P. Peters, professors. There are now 26 students.

The Episcopal Theological School of Massachusetts was established at Cambridge, 1867, by a gift of \$100,000, and began with 4 professors and Dr. J. S. Stone as dean. He was succeeded by Dr. G. Z. Gray. It has a fine chapel and three halls, valued at \$325,000, but admission is limited to college graduates, and the number of students has never been large. There are now 16, under 6 professors, and about 100 alumni.

The Bishop Green Associate Mission and Training School, at Dry Grove, Miss., was opened 1867, and is in charge of W. K. Douglas, S. T. D.

St. Augustine's Normal School, at Raleigh, N. C., opened 1867 has a theological department and some property. It is under R. B. Sutton, D. D.

Matthew's Hall, at Denver, Col., opened 1872, is controlled by Bishop Spalding.

St. Andrew's Divinity School, at Syracuse, N. Y., was opened 1876.

The University of the South, at Sewanee, Tenn., chartered 1856, organized 1876, has a theological department, with 8 professors, 20 students, 2500 volumes, and buildings worth \$50,000. Telfair Hodgson, D. D., is dean. This is a live institution, which has made head against great difficulties.

The Kansas Theological School, at Topeka, Kan., began 1874, "has merely a nominal existence." A similar institution at Louisville, Ky., exists only in "a valuable library and productive funds."

Wheeler Hall, Chicago, Ill., was opened 1885 by Bishop McLaren. It has 5 professors, 12 students, 2000 volumes, and buildings on the Washington boulevard worth \$150,000.

EVANGELICAL ASSOCIATION.

Union Biblical Institute, at Naperville, Ill., was opened 1876, with 3 teachers and 8 pupils under J. J. Esher.

The German Evangelical Theological Seminary, opened 1850 at Normandy, Mo., was afterwards removed to St. Louis, and its name changed to Eden College. It reports 3 teachers and 90 pupils under L. F. Haeberle, with real estate worth \$120,000.

LUTHERAN.

Hurtwick Seminary, founded 1815, in Otsego co., N. Y., has a small theological department, long conducted by G. B. Miller, D. D. A. Heller, D. D., is now at the head of it. A new building was erected about 1865, and a memorial volume published at Albany, 1867.

The Theological Seminary of the General Synod, at Gettysburg, Pa., was founded 1826 and chartered 1826. Its successive heads have been Drs. S. S. Schmucker, C. A. Hay, and M. Valentine. Dr. E. L. Hazelius became its second professor in 1830. Others were Drs. H. I. Smith, C. P. Krauth, Sr., C. F. Schaeffer, J. A. Brown, C. A. Stork, E. J. Wolf, and J. G. Morris. There are now 4 professors, about 40 students, a library of 11,000 volumes, 2 lectureships, an endowment of near \$100,000, and buildings worth \$75,000. The alumni number nearly 700.

The Theological Seminary of the Synod of Ohio, at Columbus, Ohio, was begun 1830. M. Loy, D. D., is

at its head, with 3 instructors, about 30 students, 4500 volumes, and real estate worth \$100,000.

The Theological Seminary of the South, at Newberry, S. C., opened 1830, has an endowment of \$22,000, 3 instructors, and a few students, under G. W. Holland.

Concordia Seminary, at St. Louis, was founded 1830 in Perry co., Mo., in a settlement of recent emigrants from Saxony. At first it included also a gymnasium or college, which was transferred to Fort Wayne, Ind., 1861. The seminary was removed to St. Louis in 1849, and passed in 1850 under the control of the Missouri Synod (afterwards the Synodical Conference). A fine building was erected 1882-3. Dr. C. F. W. Walther, long president, has been succeeded by F. Pieper. The seminary now has 6 professors and some 95 students, with a library of 5500 volumes. It has prepared near 600 men for the ministry. A branch of it, called a "Practical Seminary," was removed to Springfield, Ill., 1875, and now reports 5 teachers and 213 pupils.

Wittenberg College, at Springfield, Ohio, founded 1845, has a theological department in connection with the General Synod, which reports 2 teachers and 11 students.

Warburg Seminary, Mendota, Ill., opened 1856, is controlled by the German Synod of Iowa, and has 2 teachers and 50 students, with 3000 volumes. S. Fritschel, D. D., is its head.

The Missionary Institute, at Selinsgrove, Pa., opened 1858, is connected with the General Synod. It has a small property and endowment, 3000 volumes, 2 teachers and 12 pupils. P. Born, D. D., is at its head.

Augustana Seminary, at Rock Island, Ill., began 1860, belongs to the Swedish Augustana Synod, which is in communion with the General Council. It has real estate worth \$100,000, 2500 volumes, 3 instructors, and 48 students, under Dr. T. N. Hasselquist.

The Theological Seminary of the Evangelical Lutheran Church, at Philadelphia, opened Oct. 5, 1864, at 218 Franklin street, is controlled by the Ministerium of Pennsylvania and the General Council. It has maintained the ablest faculty and the highest character of any English Lutheran institution. Its first professors were Drs. C. F. Schaeffer, C. P. Krauth, Jr., W. J. Mann, and C. W. Schaeffer. The two first named died and were replaced by Drs. A. Spaeth and H. E. Jacobs. The library has 17,000 volumes. There are now 62 students and some 300 alumni. A collegiate education or its equivalent is necessary to entrance.

Augustburg Seminary, at Minneapolis, Minn., opened 1869, belongs to the Norwegian-Danish Conference. It has an endowment of \$46,000, 2 teachers, and 31 pupils. S. Sverdupe is at its head.

The Norwegian and Danish Augustana Seminary, at Beloit, Iowa, opened 1874, is controlled by the Norwegian Augustana Synod. D. Lysnes is its director.

Luther Seminary, at Madison, Wis., opened 1876, belongs to the Norwegian Synod, and has 20 pupils.

The Evangelical Lutheran Theological Seminary, at Milwaukee, Wis., begun 1878, is controlled by the Wisconsin Synod and the Synodical Conference. It has 3 teachers and 35 students.

The Red Wing Seminary, at Red Wing, Minn., is connected with Hauge's Norwegian Synod, and reports 5 teachers, 17 pupils, and real estate worth \$30,000.

A Practical and Theological Seminary, at Afton, Minn., opened 1881, belongs to the Joint Synod of Ohio.

Concordia College, at Conover, N. C., 1883, is directed by the Tennessee Synod and by P. C. Henkel, D. D.

Other small institutions of recent origin are reported as existing at Blair, Neb., Saginaw, Mich., Northfield, Minn., and Chicago. (See Stall's *Lutheran*

Year-Book, 1888, and *Lutheran Church Almanac*, 1888.)

METHODIST EPISCOPAL.

De Pauw University (formerly Indiana Asbury University), founded 1837, has a theological department under A. Martin, D. D., LL. D., with 5 teachers and 45 students.

Boston University has a *school of theology*, which was projected 1837 and opened 1847 at Concord, N. H., as the Methodist General Biblical Institute. Among its early professors were Drs. J. Dempster, J. W. Merrill, O. C. Baker, S. M. Vail, C. Adams, and D. Patten. It was merged with the Boston University, 1871, endowed by the founders of that institution, reorganized, and removed to Boston 1876. It has a wide curriculum, with instruction in German and Spanish, and lectures by eminent divines of other bodies. There are now 13 instructors and some hundred students, with a library of 5000 volumes, and buildings valued at \$150,000. Dr. W. F. Warren is the president. Many missionaries have gone hence to Mexico and other lands.

Garrett Biblical Institute, at Evanston, Ill., was opened 1856 and chartered 1857. The first professors were Drs. J. Dempster, D. P. Kidder, and H. Bannister, to whom were added Drs. M. Raymond and F. D. Hemenway. Dr. W. X. Ninde became president in 1879, and was succeeded by Dr. H. B. Ridgeway. There is a good building, and an endowment of some \$300,000. There are now 8 instructors, some 125 students, and nearly 500 graduates, besides many more who have taken a partial course. The institute is controlled by the Western conferences.

Wallace College (German), at Berea, Ohio, founded 1864, has a small theological department under W. Nast, D. D.

Central Tennessee College, at Nashville, opened 1866, has a theological department under J. Braden, D. D., and reports 9 teachers and 48 students.

The Gilbert Haven School of Theology in New Orleans University, La., opened 1866, reports 8 teachers, 20 pupils, and 3000 volumes in its library.

The Drew Theological Seminary, at Madison, N. J., was founded 1867 by a gift of \$250,000 from Daniel Drew. The Gibbons estate of about 100 acres, with a large mansion, was purchased, and 2 more buildings erected for students, with 2 for professors. The endowment was to have been doubled, but Mr. Drew's failure prevented. Pres. J. F. Hurst, however, procured subscriptions of \$300,000. The first president was Dr. J. McClintock, who died 1870. He was succeeded by Drs. Forster and Hurst, who became b. shops, and Dr. H. A. Beatty, also professor of New Testament exegesis. The other professors are Drs. J. Strong, J. Miley, G. R. Crooks, and D. F. Upham. There are several instructors and lecturers, some 100 students, and a library of 18,000 volumes.

The Centenary Biblical Institute, at Baltimore, Md., on the corner of Fulton street and Edmonson avenue, was chartered 1867 and organized 1872. It has 11 teachers, 55 pupils, 1000 volumes, and real estate worth \$30,000. W. M. Frysinger, D. D., is at its head.

The German-English College, at Galena, Ill., opened 1868, chartered 1871, has a theological department under E. Uhl, with 2 teachers and 12 pupils.

A Swedish Theological Seminary, at Evanston, Ill., opened 1870, is taught by A. Ericson, and has 19 students, and real estate worth \$8000. A Norwegian and Danish theological school was opened here 1886 under N. E. Simonson, and is reported as a separate institution.

A German College, at Mount Pleasant, Iowa, was opened 1873, and has 4 teachers, 24 pupils, and real estate worth \$15,000. J. Schlagenhauf is at its head.

The Gammon School of Theology of Clark University, Atlanta, Ga., opened 1883, reports 3 teachers, 53

students, 4100 volumes, and real estate worth \$65,000. W. P. Thirkield, S. T. D., is dean.

McKendree College, at Lebanon, Ill., has a theological department with 10 students.

GERMAN METHODIST EPISCOPAL.—*Central Wesleyan College*, at Warrenton, Mo., opened 1864, has a theological department under H. A. Koch, D. D., with 4 teachers and 44 students.

METHODIST EPISCOPAL CHURCH, SOUTH.—*Trinity College*, at Trinity, N. C., has a theological department. The 8 teachers and 142 pupils reported doubtless include the whole college.

Vanderbilt University, Nashville, Tenn., founded 1872-75 with the finest endowment in the South, has a Biblical department, with 12 teachers and 45 students. W. F. Tillett, D. D., is dean.

AFRICAN METHODIST EPISCOPAL.—*Wilberforce University*, at Wilberforce, Ohio, opened 1853, has a theological seminary with 5 students under S. T. Mitchell.

AFRICAN METHODIST EPISCOPAL ZION.—*Livingston College*, Salisbury, N. C., has a theological department.

METHODIST PROTESTANT.

Adrian College, Mich., opened 1878, has a school of theology, with 3 teachers and 21 students under D. L. Stephens.

Westminster Theological Seminary, at Westminster, Md., opened 1882 under J. T. Ward, D. D., reports 5 teachers, 11 students, and a small library and property.

WESLEYAN METHODIST.—*Wheaton Theological Seminary*, at Wheaton, Ill., opened 1881 under L. N. Stratton, has 5 teachers and 16 students.

MORAVIAN.

The *Theological Seminary* was opened at Nazareth, Pa., Oct. 3, 1807, with 2 professors, E. L. Hazdus and J. C. Beckler, and 3 students, who in time became bishops. It was removed to Bethlehem, Pa., 1838, and has continued there, except for a sojourn of 7 years (1851-58) at Nazareth. It was incorporated 1863 as the Moravian College and Theological Seminary, with a course of 4 years in classics and 2 in theology. It has an endowment of \$80,000, a building worth \$9000, and a library of 5500 volumes. There are 25 students under Profs. A. Schultze (president), J. J. Hamilton, C. B. Shultz, and H. A. Jacobson.

PRESBYTERIAN.

Princeton Theological Seminary, at Princeton, N. J., was founded by the General Assembly in 1812. Dr. Archibald Alexander was at its head till 1851. Dr. Samuel Miller was professor, 1813-50; Charles Hodge (q. v.), 1822-78; J. Addison Alexander, 1835-60; John Breckinridge, 1836-38; J. W. Alexander, 1849-51; and A. T. McGill, 1854-83. Dr. W. H. Green was added to the faculty 1851; C. W. Hodge, 1860; J. C. Moffatt, 1861; C. A. Aiken, 1871; A. A. Hodge (q. v.), 1877; F. L. Patton (q. v.), 1880; and W. M. Paxton, 1883. Under these scholars Princeton has always been noted for the stern consistency of its Old School theology. It has instructed some 3700 students, and now has about 140 under 11 instructors. The library has 46,000 volumes. The seminary has received many benefactions from R. and J. Lenox, R. L. and A. Stuart, and others. It is exceptionally well supplied with funds and buildings. The *Biblical Repository* and *Princeton Review*, from 1825 to 1872, under the editorship of Dr. C. Hodge, represented the "Princeton School" and its theology. The *General Catalogue* of the seminary, by Dr. W. E. Schenck, 1882, covered 330 pages.

Union Theological Seminary, at Hampden-Sidney College, Va., existed in germ at an early period, and was reformed 1812 by the Synod of Virginia. In the next 8 years it sent out some 30 licentiates. Dr. Moses Hoge, president, died 1820, and in 1824 the Hanover Presbytery established the seminary as a separate institution. It passed under the care of the

General Assembly in 1826, and was henceforth governed, through 24 trustees, by the Synods of Virginia and North Carolina, receiving its present name. Dr. J. H. Rice was in charge, 1824-31; Dr. G. A. Baxter was president, 1832-41, and Dr. S. B. Wilson from 1841. By 1831 there were buildings, a library, and 3 professors; a fourth was added 1854. The seminary now has 5 teachers, 60 students, 12,400 volumes, 40 acres, with buildings worth \$50,000, and an endowment of \$250,000.

Auburn Theological Seminary, at Auburn, N. Y., was established by the Synod of Geneva 1819, and chartered April, 1820. Ten acres were given and a building erected; afterwards enlarged at a cost of \$40,000. In 1874-75 Morgan Hall was built, 216 by 45 feet, and 5 stories in height, costing \$100,000. The Dodge and Morgan Library cost \$40,000, has room for 60,000 volumes, and now has over 16,000. The seminary is governed by trustees and commissioners, representing the presbyteries included in the Synods of Albany, Geneva, Central New York, and Western New York. The doctrinal tone is in harmony with Princeton: "No leaven of Pelagianism or Arminianism has ever found its way into this school." Each professor on entering on his office signs a declaration of belief. There are 5 chairs, of Christian theology, church history and government, Biblical criticism, Hebrew language and literature, and sacred rhetoric and pastoral theology. Dr. S. M. Hopkins is senior professor; Dr. Willis J. Beecher is professor of Hebrew. There are about 50 students and 700 graduates.

The *Western Theological Seminary* was opened at Allegheny, Pa., Nov. 16, 1827, in accordance with action taken by the General Assembly in 1825. J. Stockton and E. P. Swift, D. D., were its first teachers. Eighteen acres of ground were granted. The first building, occupied 1831, was burned 1854, and another dedicated 1856. There are now 3 halls and 5 professors' houses, valued together at \$165,000. The library has some 21,000 volumes. The government is vested in 40 directors and a board of 30 trustees, the latter incorporated 1844. Each professor at his inauguration subscribes a pledge. They number 6, with some 70 students and over 1500 alumni, among them many missionaries. There is a post-graduate course.

The *Theological Seminary of the General Assembly* (South) was begun in 1828 and chartered 1832. At first under the care of the Synods of South Carolina and Georgia, with which that of Alabama joined in 1857, it was transferred in 1863 to the General Assembly of the Presbyterian Church in the Confederate States of America, which changed its name after the war. Among the professors were Drs. J. H. Thornwell (theology), 1855-62, and Howe (Hebrew), 1831-83. The seminary had in 1863 a good endowment, which was largely destroyed by the war, and not replaced till 1882, when the school, after being closed for 2 years, was reopened with 5 professors and some 25 students. Prof. Woodrow was suspended in 1886 on account of his showing favor to evolution. He was afterwards tried for heresy, but acquitted. The seminary was closed in 1886.

Lane Theological Seminary, at Cincinnati, Ohio, was begun as a preparatory school Nov. 18, 1829, 60 acres at Walnut Hills and a small sum of money having been given. The academy was abandoned in 1834 and the theological department opened in December, 1832, with Drs. Lyman Beecher and T. J. Biggs as professors. Dr. Calvin E. Stowe came in 1833 and Dr. B. Dickinson in 1835. An exodus of students occurred 1834. (See *Oberlin*.) Dr. D. H. Allen was professor of sacred rhetoric, 1840-51, and of systematic theology, 1851-67, when he was succeeded by H. A. Nelson, D. D. Dr. G. E. Day was professor of Biblical literature, 1851-66; Dr. T. E. Thomas of New Testament literature, 1871-75; Dr. H. Smith of sacred rhetoric, 1855-61 and 1865-79; and Dr. Z. M. Humphrey of church history, 1873-81. There are 5 professors and

about 40 students, a library of 13,000 volumes, a fair endowment, and good buildings. Near 800 graduates have gone into the ministry, mostly west of the Alleghenies.

Union Theological Seminary, New York city, was projected October, 1835, a board of directors chosen 1836, and a charter obtained March, 1839. Instruction was begun Dec. 5, 1836. A building on University Place was dedicated Dec. 12, 1838. Endowment came slowly, but now exceeds \$1,000,000, besides special funds. In 1884 a larger edifice, at 1200 Park avenue, was completed and occupied. The real estate is valued at \$700,000. Among the professors have been Drs. Edward Robinson, H. White, H. B. Smith, T. H. Skinner, William Adams, and Roswell D. Hitchcock. The faculty at present consists of Drs. W. G. T. Shedd, systematic theology; P. Schaff, church history; G. L. Prentiss, pastoral theology; C. A. Briggs, Hebrew; T. S. Hastings, sacred rhetoric; Francis Brown, Biblical philology; M. R. Vincent, sacred literature. There are also two instructors, a superintendent of mission work, a librarian, and three lectureships. In 1887-88 there were 132 students. The library began with that of Dr. L. Van Ess, purchased in Germany 1838, and now includes 55,000 volumes, besides many pamphlets and MSS. There are some 1500 alumni, among them over 130 foreign missionaries. The theology taught is of the New School type; the General Assembly has no control over the seminary beyond a veto (since the reunion in 1870) on the appointment of professors. A board of 28 directors, one-half laymen, govern the institution; they and the professors promise adherence to the Westminster Confession and to the Presbyterian form of government.

Danville Theological Seminary was opened 1853 at Danville, Ky. It has four professors, S. Yerkes being the senior professor, 11 students, 8000 volumes, and real estate worth \$10,000.

The *German Presbyterian Theological School of the North-west* at Dubuque, Iowa, was begun 1852, organized 1856, and chartered 1871. It has four professors, 28 students, 2000 volumes, and real estate worth \$25,000. A. J. Schlager, D. D., is chairman of the faculty.

The *McCormick Theological Seminary*, till lately the *Presbyterian Theological Seminary of the North-west*, is in Chicago, at 1060 N. Halsted street. It was chartered 1856 and opened 1859, and has recently received the stimulus of valuable benefactions. Its real estate is valued at \$200,000, and it has a library of 10,000 volumes. This is one of the most important theological schools of the West, with 11 instructors and 100 or more students. Dr. Le Roy J. Halsey is president.

Biddle University, at Charlotte, N. C., for colored students, opened 1868, has a theological department with 11 students, under S. Mattoon, D. D.

Lincoln University, Pa., founded 1871 for colored students, reports a theological department under I. N. Rendall, D. D., with 8 teachers and 31 pupils.

The *German Theological School of Newark* was opened 1869 at Bloomfield, N. J., and chartered 1871. It reports 6 teachers and 28 students under C. E. Knox, D. D., with 3000 volumes and real estate worth some \$18,000.

San Francisco Theological Seminary, Cal., organized 1871, chartered 1876, has 16,000 volumes and real estate worth \$24,000, but very few students. T. Fraser is at its head.

An *Institute for Training Colored Ministers* was opened 1877 at Tuscaloosa, Ala. It reports 3 teachers and 19 pupils under C. A. Stillman, D. D.

UNITED PRESBYTERIAN.

The *U. P. Theological Seminary of Xenia, Ohio*, antedates almost all other existing theological schools in America, having been founded by the Associate Synod in 1794. It was long maintained at Canons-

burg, Pa., and was removed to Xenia in 1860, but not chartered till 1877. It has 4 teachers and 36 students under Dr. James Harper, with 4000 volumes and real estate worth \$15,000.

The *Theological Seminary of the U. P. Church*, at Allegheny City, Pa., was established 1825 and chartered 1868. It has 11 instructors, 36 students, 3100 volumes, and real estate valued at \$40,000.

The *Reformed Presbyterian Theological Seminary*, also at Allegheny City, Pa., opened 1856, has 3 teachers and 21 students, with 2800 volumes and real estate worth \$25,000. Dr. D. B. Willson is dean.

Another Reformed Presbyterian Theological Seminary is conducted in Philadelphia by Rev. David Steele, D. D.

CUMBERLAND PRESBYTERIAN.

The *Cumberland University at Lebanon, Tenn.*, chartered 1842, opened 1852, has a theological department, with 7 teachers, 27 students, 5000 volumes, and real estate worth \$10,000. N. Green, LL. D., is chancellor.

Trinity University at Tehuacana, Texas, opened 1871, has a theological department, but the 12 teachers and 300 students reported probably represent the entire college.

The *Associate Reformed Theological Seminary at Due West, S. C.*, opened 1840, reports 4 teachers and 6 students under Rev. W. M. Grier, D. D.

REFORMED CHURCH.

Dutch Reformed.—The venerable body, commonly distinguished as Dutch Reformed, wisely contents itself with a single theological seminary. The Dutch churches in America till 1771 were subject to the classis of Amsterdam, which then made it a condition of their independence that measures be speedily taken for theological education. Nothing was done till after the Revolution. In October, 1784, the Synod appointed J. H. Livingston, D. D., of New York, professor of theology, and H. Meyer, of Pompton, N. J., instructor in the "inspired languages." The former delivered an inaugural oration May 19, 1785, in New York, and began to receive students at his house; for a time he taught also at Flatbush, L. I. Synod appointed "lectors in theology," living elsewhere, with whom young men should study, that they might be examined and certified by Dr. Livingston. Two other professors at one time received students at their homes. By arrangement between the General Synod and the trustees of Queen's (now Rutgers) College, at New Brunswick, N. J., Dr. Livingston became its president, and removed thither 1810, having up to that time certified about 90 candidates. In 1812 the General Synod adopted a plan for the full organization and government of the school, and provided for the appointment of a board of superintendents. A second professor was appointed 1815, a third 1825, and a fourth 1865. Synod controls the seminary and elects its professors, who promise strict adherence to the Heidelberg Catechism, the Belgic Confession, and the canons of the Synod of Dort. The buildings are on grounds given by 3 patrons, and include 2 halls, a library, and 5 residences, in all valued at \$350,000. The seminary is well endowed; 2 benefactors together gave near half a million, and each endowed a chair. There are now 6 professors and 22 students; the library contains some 60,000 volumes. S. M. Woodbridge, D. D., is dean.

The *Western Seminary*, at Holland, Mich., opened 1866, has 3 teachers and 8 pupils under M. N. Steffens, D. D. This institution is the product of direct emigration from Holland.

GERMAN REFORMED.

The *Theological Seminary of the Reformed Church*, now at Lancaster, Pa., was opened March 11, 1825, at Carlisle, Pa., with 5 students and 1 professor. It was

removed to York 1829, and chartered 1831. In 1837 it moved to Mercersburg, the seat of Marshall College, where it developed the "Mercersburg Theology." In 1871 it followed the college to Lancaster. The professors of theology have been Drs. L. Mayer, J. W. Nevin (*q. v.*), B. C. Wolff, H. Harbaugh, and E. V. Gerhart. A chair of church history and exegesis, founded 1829, has been filled by D. Young, F. A. Rauch, and Drs. P. Schaff, E. E. Higbee, and T. G. Apple. A tutorship existed 1861-73. F. A. Gast took the new chair of Hebrew 1873. The seminary is controlled by three synods, through a board of trustees and one of visitors. It has a fair endowment (largely raised in Germany), a building worth \$20,000, a library of 10,000 volumes, 31 students, and 4 professors. Dr. E. V. Gerhart is at its head.

Heidelberg Theological Seminary, at Tiffin, Ohio, was established by the Ohio Synod and opened in May, 1851. Dr. E. V. Gerhart served alone till 1855, and was succeeded by Dr. M. Kieffer. The faculty now consists of Drs. J. H. Good (1869) and H. Rust (1861). There are 18 students, some 225 alumni, 3000 volumes, and an endowment of about \$30,000.

A *Mission House*, at Franklin, Wis., opened 1860, reports 7 teachers under H. A. Muehlmeier, D. D., and 4200 volumes. The number of students is not given.

Ursinus College, at Freeland, Pa., 30 miles northwest of Philadelphia, opened 1870, has a theological department, with 4 teachers, 10 students, and about 60 graduates. It was recognized by the General Synod in 1872. J. H. A. Bomberger, D. D., is president.

ROMAN CATHOLIC.

The *Theological Department of St. Sulpice and St. Mary's University*, Baltimore, Md., organized 1791, chartered 1860, has 8 teachers, 220 pupils, a library of 26,000 volumes, and real estate valued at \$150,000. A. Magnien, D. D., is at its head.

Theological Department of Mount St. Mary's College, Emmitsburg, Md., organized 1808; 27 teachers, pupils not reported; 10,000 volumes, real estate, \$150,000. E. P. Allen.

St. Vincent's Seminary, Germantown, Philadelphia, organized 1818; 6 teachers, 10,000 volumes. T. J. Smith.

Philadelphia Theological Seminary of St. Charles Borromeo, Overbrook, Pa., opened 1832, chartered 1838; 8 teachers, 106 pupils, 15,600 volumes. W. Kieran, D. D., vice-rector. This is one of the most important Roman Catholic institutions.

Augustinian Monastery of St. Thomas of Villanova, Villanova, Pa., organized 1842, chartered 1848; 8 teachers, 21 pupils in the "ecclesiastical department." T. C. Middleton, D. D.

St. Vincent's College and Theological Seminary, Cape Girardeau, Mo., chartered 1843, opened 1844; 10 teachers, 8000 vols. P. McHale.

St. Vincent's College, Beatty, Pa., opened 1846; 6 teachers, 37 pupils in theological course, 24,300 vols. D. Block.

St. Mary's Theological Seminary, Cleveland, Ohio, opened 1849; 5 teachers, 30 pupils, property valued at \$75,000. N. A. Moes.

St. Meinrad's Seminary, St. Meinrad's, Ind., opened 1854; 5 teachers, 8000 vols. F. Mundwiler.

Seminary of St. Francis of Sales, St. Francis, Wis., opened 1855, chartered 1877; 12 teachers, 110 pupils, 12,000 vols., real estate worth \$100,000. A. Zeininger, rector.

Diocesan Seminary of the Immaculate Conception, South Orange, N. J., opened 1856; 4 teachers, 15 pupils, 5200 vols. W. P. Sact, director.

College and Seminary of our Lady of Angels, Suspension Bridge, N. Y., opened 1856, chartered 1863; 7 teachers, 66 pupils. P. V. Kavanaugh.

St. John's University, Collegeville, Minn., formerly *St. John's Seminary*, St. Joseph, Minn., opened and

chartered 1857; 6 teachers, 22 pupils in "ecclesiastical course." A. Edelbrock.

St. Bonaventure's Seminary, Allegeny, N. Y., opened 1859; 8 teachers, 74 pupils, 6000 vols. T. Pospisilik.

St. Joseph's Provincial Seminary, Troy, N. Y., organized 1864; 7 teachers, 120 pupils, 9000 vols., real estate worth \$200,000. H. Gabriels, D. D. This ranks with or possibly above the seminary at Overbrook, Pa.

St. Charles Borromeo Theological Seminary, Carthagen, Ohio, opened 1864; 19 teachers, 45 pupils. T. Wittmer.

Mt. St. Clement, Ilchester, Md., opened 1868; 11,000 vols., \$60,000 in real estate. E. Grimer.

Woodstock College, Woodstock, Md., chartered 1867, opened 1869. Conducted by Jesuit Fathers. No report.

Preston Park Theological Seminary, Louisville, Ky., opened 1870. No report.

Theological Department of St. Viator's College, Bourbonnais Grove, Ill.; 3 teachers, 29 pupils. M. J. Marsile.

College of the Sacred Heart, Vineland, N. J.; 7 teachers, 20 pupils. E. H. Porcile.

There are also said to be seminaries at Santa Barbara, Cal., and New Orleans, La., which made no report.

SWEDENBORGIAN OR NEW CHURCH.

Theological School, at Waltham, Mass., opened 1866.

Urbana University, Urbana, Ohio, had in former years a theological department, but this is extinct.

UNITED BRETHREN IN CHRIST.

Union Biblical Seminary, Dayton, Ohio, organized and chartered 1871, has 4 teachers, 40 students, a library of 1100 volumes, an endowment of \$100,000, and \$25,000 in real estate. G. A. Funkhouser, D. D.

UNITARIAN.

The *Divinity School of Harvard University*, now professedly non-sectarian, made its mark and attained its reputation in the service of this body, and sent forth most of its ministers. Harvard College began in 1636 as a seminary for preachers, with a limited academical course. The first chair was that of divinity, endowed by T. Hollis, an English Baptist, 1721. The first chair endowed by a native of New England (T. Hancock) was that of Hebrew. The Divinity School began to have a separate existence in 1815, and was organized 1819. For near 60 years the chairs were occupied solely by Unitarians, among them many eminent men, as Drs. Ware, Norton, Peabody, Hedge, and Abbott. The graduates were a numerous body of the highest culture, and very many of them attained distinction. Of late no doctrinal restraints exist. Lectures have been delivered by a Trinitarian, and the appointment of an "orthodox" professor of dogmatic theology has been sought for years. There are now 6 professors, 21 students, 17,000 volumes, and real estate worth \$100,000. C. C. Everett, D. D., is dean of the school.

Meadville Theological School, Meadville, Pa., was founded 1844 by the Unitarians and the Christian Connection and chartered 1846. A belief in the divine origin of Christianity is the only doctrinal test. The successive presidents have been Drs. R. P. Stebbins, 1844-56; O. Stearns, 1856-63, and A. A. Livermore. Divinity Hall was erected 1854, and a fire-proof building holds a library of 18,000 volumes. The real estate is worth \$30,000 and the endowment is \$160,000. Two professors and an instructor are resident, and 3 give part of their time. There are about 30 students and 400 who have been such. A partial course is given besides the regular one of 3 years.

UNIVERSALIST.

Canton Theological School, Canton, N. Y., was organized and chartered 1858. It has 5 teachers, 14

students, a library of 7800 volumes, and real estate worth \$30,000. J. M. Atwood, D. D., is at its head.

Tufts College, at College Hill, Mass., has a Divinity School which was opened 1869, and made rapid progress. Drs. T. J. Sawyer and C. H. Leonard were the first professors. In 1875 a four-years' course was provided for non-graduates, and the faculty increased; it now numbers 7 professors and instructors. E. H. Capen, D. D., is president. There are 34 students and about 100 graduates.

Lombard University, Galesburg, Ill., has a theological department opened 1881. It reports 7 teachers and 11 students under N. White.

UNDENOMINATIONAL.

Howard University, at Washington, D. C., opened 1870, has a theological department under J. C. Craighead, with 5 teachers and 53 students.

JEWISH.

The *Hebrew Union College*, at Cincinnati, Ohio, was organized 1875. It has 6 teachers, 32 pupils, 9500 volumes, and real estate worth \$30,000. J. M. Wise is at its head.

From the above statistics it will appear that theological seminaries, no less than colleges, multiply beyond any very pressing demand for their services, or at least beyond the power and will to sustain them. It is a common remark that a moderate number of strong institutions would be better than a plethora of feeble ones. But the American tendency is to bring education, professional as well as general, as near as possible to every man's door, and in the strife of sects each wishes to be represented, as nearly as it can, in every part of the country. The moral is obvious, but is usually unheeded. With several of the denominations one-third or more of their schools might be wiped out without special injury, and this process is not unlikely to take place to some extent. (F. M. B.)

THERMOMETER. This familiar instrument for

determining the temperature of air or other fluid is usually filled with mercury; but many thermometers for special uses are filled with colored alcohol. The mercury or alcohol is contained in a glass ball from one side of which arises a long and thin hollow tube with a very small bore, and the ball and tube are fastened upon a flat piece of metal or wood upon which are marked various degrees. The uniformity of the bore is tested by introducing a small quantity of mercury and moving it along the tube from end to end by air forced out of a small india-rubber ball attached to one extremity. If the column is observed to occupy the same space throughout the bore is considered to be of uniform diameter. This process is called the calibration of the tube. The ball, or bulb, and part of the tube are filled with mercury that has been strained through chamois leather. In the usual process of filling thermometers a lamp is held to the bulb until the air is highly rarefied; the end of the tube is then placed in a vessel of mercury, the lamp removed, and the mercury rises in the tube by the cooling and condensing of the air in the bulb. The bulb is then held downward and the mercury heated so that, in expanding, it entirely fills the tube. Then the top of the glass tube is sealed with a blow-pipe; and the mercury, contracting as it cools, falls down in the tube toward the bulb, leaving above it a vacuum. Upon the application of heat to the bulb the mercury expands and rises in the tube in proportion; or it shrinks and drops in the tube as it cools. Besides the bulb and the tube it is necessary to have a graduated scale in order to make the instrument of practical service. The three principal scales in use are Fahrenheit's, Reaumur's, and the Centigrade. The scale used for ordinary purposes, both in England and the United States, is Fahrenheit's, although both this and Reaumur's are sometimes marked on the same in-

strument. Fahrenheit's scale is formed thus: The bulb of the thermometer is placed in boiling water, and the height to which the mercury rises is marked by a scratch on the tube; it is then put into melting snow or ice, and another scratch is made at the point where the mercury has descended. The space between these two marks is divided into 180 equal parts, called degrees, and these divisions are carried upward to nearly the end of the tube, and downward toward the bulb; the upper scratch, indicating the heat of boiling water, is marked 212, and the lower one, the freezing point of water, is 32. The zero point was intended to mark the temperature of a mixture of snow and salt, which was supposed to be the utmost possible natural cold. On the scale of Reaumur's thermometer the zero is at the freezing point of water, and the boiling point is marked 80. The Centigrade differs from Reaumur's only in having the space between the boiling and freezing point of water divided into 100 parts instead of 80. The "register thermometer," or "maximum and minimum thermometer," has two bulbs, tubes, and scales on the same instrument; one bulb is filled with mercury and the other with colored spirit. In each tube a piece of enamel, about half an inch long and fitting the cavity, is introduced; the one in the mercury is to register the highest, and that in the spirit to register the lowest, degree of heat. They act in the following manner: The spirit, when rising in the tube, wets the enamel and passes by it so that the elevation of temperature does not affect its position, but when the spirit sinks it carries the enamel with it, thus registering the lowest temperature, so that the distance the enamel is found down the tube indicates how low the spirit may have descended in any particular time, say a night. Mercury, on the other hand, does not adhere to the enamel, and therefore, on rising, pushes it up in the tube, but on descending leaves it behind, the height at which the enamel is found up the tube indicating the highest point to which the mercury had risen, and consequently the highest temperature. To adjust the instrument, a slight tap or shake will make the index in the spirit-tube rise to the surface of the liquid, where it is held by the adhesive quality of the liquid, and by the same process that, in the mercurial tube, will fall to the surface, but will not penetrate the mercury, owing to its great density.

In making very accurate thermometers the boiling point is found by immersing the instrument in steam and not in the water itself, as water really boils at different temperatures depending upon various circumstances, whilst the temperature of the steam is uniform. Even with the greatest care in constructing, the indications of a thermometer are liable to derangement; and this result may come more particularly from the bulb not resuming its former capacity after being heated to a high temperature. Such a fault as this may not be discovered until comparison has been made with thoroughly reliable thermometers.

Aside from the thermometer certain appliances must be used to assist in case of finding temperature in inaccessible places, like the different depths of the sea, etc. Siemens has invented a method of ascertaining the temperature at such depths, depending on the principle that the electric resistance of metals is in proportion to the increase of their temperature. The process requires two coils of the same kind of platinum wire which shall have equal resistance. The ends of the wires are connected with long and thick copper wires; so that, if necessary, the coils may be placed at a considerable distance from the galvanometer. The copper terminals are adjusted so that each coil shall have the same resistance; but such resistance should be small in comparison with the resistance of the coils themselves. One of the coils is sunk to the required depth in the sea, and the other is placed in a jar of water on the deck of the ship. The temperature of the water in the jar is adjusted until the

resistance of both coils is the same. Thus, the temperature of the water in the jar is made the same as that of the sea-water at the depth of the lower coil. The thermometer showing the temperature of the water in the jar will, therefore, show the temperature of the water at the depth required.

For the mutual conversion of the three standard thermometric scales, Fahrenheit's, Reaumur's, and the Centigrade, the following formulæ are convenient: $F:C:R::180:100:80=9:5:4$. Therefore, $F=\frac{9}{5}C$; $F=\frac{9}{4}R$; $C=\frac{4}{5}R$. Of course to convert F. degrees into C. or R. degrees 32 must be subtracted before (and in the converse problem added after) either of the first two formulæ is applied. (F. G. M.)

THESSALONIANS, EPISTLE TO. See ROMANS, EPISTLE TO.

THISTLE is the common name given to several genera of *Compositæ*. The thistles See Vol. XXIII. of the United States chiefly belong to p. 306 (p. 327 the genus *Cirsium*, of which we have Am. Rep.). about 20 species. They are distinguished by perfect and similar flowers, of tubular form and grouped in many-flowered heads. They have bristly receptacles, corollas of purple or reddish color, oblong smooth achenia, and a plumose pappus.

Most of the thistles are useless and troublesome weeds, one of our introduced species being among the worst pests of agriculturists. This is the Canada thistle (*C. arvensis*), which has extended throughout the United States and over the agricultural districts of Canada. It is a low, branching plant, with extensively creeping roots; affects cultivated fields and pastures, and is extremely difficult to eradicate. It can be got rid of only by plowing and persistent extraction of the roots. The most common of our thistles, *C. lanceolatum*, is also an introduction from Europe. It is found in over-abundance on road-sides and in thick pastures, has very prickly stem leaves, and bears numerous handsome purplish flowers. The common yellow swamp-thistle extends from Massachusetts to the South, where there is another yellow thistle, *C. horridulum*, a tall, rough, disagreeable sea-coast plant, well named the horrid thistle. Of species of other genera may be named *Onopordion acanthium*, the cotton thistle, a tall, showy plant, with large light-purple flowers; and *Centaureia americana*, a handsome species of the South-western States, which is cultivated in gardens. Many plants are called thistles which belong to quite different families from the typical thistles. (C. M.)

THOMAS, GEORGE HENRY (1816-1876), one of the most illustrious generals of the American civil war, was born in Southampton co., Va., July 31, 1816. His father's family, originally Welsh, had by long residence become English before emigrating to America; his mother was of Huguenot extraction. When a boy Thomas learned by watching workmen to make a saddle, boots, and furniture and thus cultivated habits of observation and combination that stood him in good stead in his future career. The first twenty years of his life were spent at home and in attendance at Southampton Academy. On leaving school he entered the office of his maternal uncle, James Rochelle, county clerk, but on being offered a cadetship in West Point he gladly gave up law for arms. He entered the academy in June, 1836, and in 1840 graduated twelfth in a class of 42, and was commissioned second-lieutenant in the Third artillery. His company was ordered to Florida, and there he remained till the termination of the Seminole war. In 1841 he took part in the capture of 70 Seminole Indians, and was brevetted first-lieutenant "for gallantry and good conduct in the war." In 1844 he was promoted to first-lieutenant and joined his company at Fort Moultrie. His next service was in Mexico under Gen. Taylor, where he was brevetted captain "for gallant and meritorious conduct" in the battles about Monterey, and major for his conduct in the battle of Buena Vista. In

1847 the citizens of his native county, proud of his achievements, presented him with a sword. In 1851 he was assigned as instructor of artillery and cavalry at West Point, and while there married, in 1852, Miss Frances S. Kellogg, Troy, N. Y.; receiving his promotion to a captaincy September, 1853. In 1855 he was appointed major of the Second cavalry and, in the following year, went with his new regiment to Texas where he remained till 1860. During this time he accompanied an expedition to the Canadian and Red Rivers, and another to the Conchas River, Mexico, where he received his only wound from a band of predatory Indians. An arrow which had transfixed his chin and penetrated his breast he drew out with his own hand. In 1860 while he was on his way home on leave of absence his spine was injured in a railroad accident, and to this has been attributed his slow riding and deliberate movements so much commented on during the war. In 1861 he applied for the position of instructor of cadets in Lexington Military Institute, Va., and this application, though unsuccessful, roused a suspicion of his loyalty that tended afterwards to impede his well-merited promotion. When the Legislature of his native State in April, 1861, voted for secession, Major Thomas remained faithful to the Union, and his first service in the civil war was, on April 21, to aid in quelling a secession mob in Maryland.

Vacancies occurring rapidly through resignation, on April 25 he was promoted to the lieutenant-colonelcy, and on May 5 to the colonelcy of his regiment, now known as the Fifth cavalry. The first service rendered by the new colonel was under Gen. Patterson against "Stonewall" Jackson at Falling Waters. When Patterson's failure to hold Gen. Jos. E. Johnston subjected him to obloquy, Col. Thomas spoke out loyally in his behalf. In August, 1861, he was appointed brigadier-general of volunteers and was assigned to the command of Fort Dick Robinson, Ky., where he found 6000 raw troops. While in Washington, Thomas had suggested the occupation of Tennessee and the seizure of the railroad connecting Richmond with the South-west, and was mortified to learn, while increasing and organizing his force with this view, that his plan had been accepted but its execution given to Gen. O. M. Mitchel. His own immediate duty was to resist the advance of the Confederates, who under General Zollicoffer had invaded Kentucky by way of Cumberland Gap (*q. v.*). A force sent out by Thomas drove the enemy back into the Gap, immediately on which he began preparations for invading East Tennessee, when an order from Gen. D. C. Buell, now commanding the department, required him to move his whole command to Lebanon, Ky. Here Thomas organized the first division of the Army of the Cumberland, whence he threw out reinforcements to Gen. A. Schoepf to aid him in preventing Zollicoffer crossing the Cumberland. In spite of opposition Zollicoffer with 8000 men crossed the river, and intrenched himself opposite Mill Spring. Thomas's whole force took the field on the last day of the year, and, after a laborious march of 19 days, reached Logan Cross-Roads, 10 miles south of Mill Spring, where he halted for the arrival of Schoepf with whom he was to make a conjoint attack on the enemy's position. He was, however, forestalled by Zollicoffer, who, anticipating an easy victory, left his lines and on Jan. 19 made an attack on Thomas' camp, driving in his pickets. Thomas rapidly formed his line and by a brilliant charge forced the enemy back to their intrenchments. Being joined by Schoepf, preparations were made for an assault on the intrenchments on the 20th, but during the night Zollicoffer crossed the river and escaped, leaving his artillery and supplies to the victor. By this action—the first Union victory in Tennessee—10,000 men were eliminated from the operations that followed.

The capture of Forts Henry and Donelson compelled the evacuation by the Confederates under Gen. A.

Sydney Johnston and Beauregard of Columbus, Bowling Green, and Nashville, and Gen. Thomas was ordered to report at the last place, where he remained as Buell's reserve till April. After the battle of Shiloh he joined the main army under Gen. H. W. Halleck—who now left his head-quarters at St. Louis—in its advance on Corinth. Halleck, who was not quite satisfied with Grant's management at Shiloh, appointed him second in command, thus relieving him of the command of the Army of the Tennessee which he conferred on Thomas. At Corinth, Thomas, learning that Grant felt hurt, asked to be relieved from the Army of the Tennessee, and restored to his old command in the Army of the Cumberland, which reduced him from the leadership of five divisions to that of one. On June 10 the transfer was effected and he joined Buell at Nashville, being put in command of the post while Buell started for Kentucky to check Bragg. In September he joined Buell at Cave City and was placed second in command, holding this position during Bragg's invasion and till Buell's withdrawal to Louisville. Here an order came from Washington relieving Buell of the command and conferring it on Thomas, but the latter again generously declined the promotion, on the ground that it was unjust to relieve a commander on the eve of a battle for which he had made preparation, his force having been augmented to 100,000. On Oct. 7 the army moved out of Louisville with Thomas in command of the right wing. On the 8th the battle of Perryville was fought, principally by the left wing under McCook, the right, from its position, being unable to take part except with its cavalry as skirmishers. The action was sanguinary, and the enemy retired across the Cumberland toward Murfreesboro; but there was no effective pursuit.

The dissatisfaction at Washington with the results of this battle led to the nomination of Rosecrans to supersede Buell. Thomas felt himself aggrieved by the appointment, and protested against it as subordinating him to a junior, but without avail. Rosecrans offered to continue him as second, but he preferred a distinct position and was assigned to the command of the centre, composed of four divisions. The entire force now marched to the vicinity of Nashville. In the advance against Bragg at Murfreesboro, begun on Dec. 26, Thomas marched with only two divisions—Rousseau's and Negley's—and two detached brigades, the troops left to maintain communication with Louisville having been withdrawn from him. At the battle of Stone River (*q. v.*), on Dec. 31, Thomas through the exhibition of his pre-eminent qualities of calm resolution, self-reliance, and immovable firmness, saved the day from being a Union defeat. When his supports were driven back in confusion he alone held the enemy at bay, changing his front and shifting his position in face of a victorious foe, and thus enabling Rosecrans to form that second line that, next morning, struck the enemy with amazement. But for Thomas the Union army would have been withdrawn to Nashville. At the council held late at night Gen. Thomas fell sound asleep. When it was decided to withdraw, and Rosecrans awoke him with the question: "Will you protect our retreat?" he simply answered: "This army can't retreat," and fell asleep again. It was Thomas who, on Jan. 2, mainly baffled Breckinridge's assaults, and who ultimately drove Bragg out of Murfreesboro.

For six months after this battle Rosecrans lay at Murfreesboro. In the series of brilliant strategic movements which began in the latter end of June, and which resulted in the Confederates evacuating Chattanooga, Thomas bore a distinguished part. But it was at Chickamauga (*q. v.*) that he earned the title that so aptly characterized him—"The Rock of Chickamauga." On the first day it was mainly by his corps that the enemy's onslaughts were repulsed. During the night Bragg was reinforced by Longstreet, and next day the assaults were renewed with redoubled

vigor in the hope of piercing the Union lines. At length the supports on Thomas' flanks were broken, and McCook's and Crittenden's corps routed, streaming in such confusion to Chattanooga that Rosecrans believed himself defeated and so telegraphed. But Thomas stood unshaken, and here, as at Murfreesboro, saved a lost battle to the Union. Wheeling his lines within the defile of Frick's Gap, whose steep sides protected both his flanks, he grandly withstood all onsets till the baffled enemy ceased his efforts. Garfield, chief of Rosecrans' staff, hearing the noise of continued fighting, halted in his flight, and rode back to the scene of conflict. "Never," says he, "will I forget my amazement and admiration when I beheld that grand officer holding his own, with defeat on every side." During the night he led his corps back to the lines of Rossville, and next evening conducted it in perfect order to Chattanooga. Rosecrans made no overstatement when he wrote: "To Thomas, the true soldier, the prudent and undaunted commander, the modest, uncorruptible patriot, the thanks of the country are due for his conduct at the battle of Chickamauga."

On Oct. 19 Rosecrans was relieved of his command. Thomas was most justly appointed his successor, and, on the 27th, made brigadier-general of the regular army. On assuming command he at once addressed himself to strengthening the fortifications of Chattanooga and securing supplies, as well as to making preparations for the advance planned by Gen. Grant, who had taken command of the entire Division of the Mississippi. On Nov. 4, by a bold dash, he made himself master of the enemy's works at Orchard Knob, commanding part of the fortifications on Missionary Ridge, and on the next day his Fourth corps, under Gen. Joseph Hooker, made its great charge up the steep side of the hill, swept across it, and broke the Confederate centre. The battle of Missionary Ridge was won; Bragg was in full flight; the Union arms held the key of the central regions.

Gen. Thomas had now a long period of rest. When Grant was promoted to be lieutenant-general the command of the Military Division of the Mississippi devolved on Gen. Sherman, and Thomas was placed under him. Though thus made subordinate to his junior, he was too patriotic to show offence, and promptly yielded him obedience.

On May 7, 1864, Sherman put his legions in motion against Gen. Joseph E. Johnston on their famed march on Atlanta, and Thomas' old Army of the Cumberland, consisting of the corps of Howard, Palmer, and Hooker, in all 60,000 strong, constituted the centre, and made the opening demonstration on Buzzard's Roost and Rocky-Face Ridge. On May 15 Thomas drove the enemy from the hills in his front at Resaca. Thereafter he assaulted the fortifications at New Hope Church; took part in severe conflicts near Dallas; on June 22 repulsed the sudden onset of Hood's corps; and on the 27th led his columns in their disastrous attack on the enemy's strong position on Kennesaw Mountain. It was his command that, on July 20, met and repelled Hood's furious onslaught with severe loss, and Palmer's corps supported the Fifteenth in beating back the magnificent Confederate charge on the 28th. On Sept. 1, at Jonesboro', his Fourteenth corps carried the enemy's intrenchments, making prisoners of nearly an entire brigade, while Slocum, with his Twentieth corps, entered Atlanta, and completed the great task. There were, indeed, few great battles on this wonderful march, but in nearly every encounter Thomas took a part. To Sherman is due the merit for the grand scheme of the campaign, but his plans would never have borne their full fruit but for the hearty and intelligent co-operation of his subordinates, among whom Thomas held the first place.

Now came a total change in the Confederate plans. Hood had superseded Johnston, and, instead of

attempting directly to impede Sherman's advance, thought to draw him back from the South by himself making a demonstration against the North. Moving, therefore, from before Sheridan westward, he turned north, his objective point being the Ohio. As soon as he began his northward march Sherman despatched Thomas to Nashville to check Hood and protect his own rear, but still proceeded on his "march through Georgia, smashing things to the sea." Thomas had under him on reaching Nashville only 22,000 infantry and 7700 cavalry, with sundry small garrisons and detachments guarding railroads. At this city, while waiting the arrival of Gen. A. J. Smith, he occupied himself in strengthening his army, having given Gen. Schofield instructions to impede Hood's advance, and, when seriously threatened, to fall back on Franklin. This movement Schofield successfully effected. When Hood assailed his lines there on Nov. 30 he drove him back with a loss of 6000 men. (See FRANKLIN.) During the night Schofield fell back on Nashville, and on the same day Gen. Smith's command arrived. Hood followed Schofield to Nashville, and now professed to besiege it. A terrible awakening awaited him. On Dec. 15 Thomas, sallying forth, made his grand attack, and rolling up Hood's lines from left to right, drove him for eight miles to a position he had previously selected. In front of this position the Union troops bivouacked, and, on the 16th, renewed the assault, carrying the enemy's works and driving it in front before them till darkness put an end to the pursuit. "Our line," says Hood, "was broken at all points, and, for the first and only time, I beheld a Confederate army abandon the field in confusion." Next day the chase was resumed, and continued unremittingly till the 29th, when Thomas learned that Hood had crossed the Tennessee at the head of "a disheartened and disorganized rabble of half-armed, barefooted men." For this decisive success Thomas was created major-general in the regular army, and received a vote of thanks from Congress. On the first anniversary of the battle he was presented with a gold medal by the State of Tennessee.

The battle of Nashville closed the last campaign in the West. During the final battles before Richmond Thomas remained in command of his department. He was not idle, however, but contributed to crushing out secession by organizing raiding bands, that resulted in the capture of Jefferson Davis. On June 30, 1865, under the act of Congress dividing the country into districts, Thomas assumed the command of the Military District (afterwards the Department) of Tennessee. This he held till March, 1867, when he was assigned to the Third Military District, comprising Georgia, Florida, and Alabama. While here he declined, in 1868, the rank of lieutenant-general, on the ground that it came too late, if intended as an acknowledgment of his service during the war, and that since the war he had done nothing deserving it. From May, 1869, he commanded the Military District of the Pacific, with head-quarters at San Francisco, where his death occurred March 26, 1876.

Gen. Thomas was a true man; spotless in character, a hater of ostentation, reserved even to reticence, self-poised, steadfast. In his manner and habits of thought he was deliberate, some thought to excess; his plans were slowly evolved and carefully matured; he never moved till he had perfected every detail, so that, when he did move, it was to assured success. No contingencies arose to perplex him, for he had prepared for all emergencies. His imperturbability in battle was amazing, and has already been referred to as eliciting the admiration of Garfield. He was, above all others, a man of system. At Chickamauga, when the enemy had routed the corps supporting him and had opened fire on his flanks and front, he replied to Steadman, who had reported to him, and who asked how the fight was going: "The scoundrels have no system." As might be inferred, the confidence of his

troops in him was complete; and this is evidenced by one of the names they gave him—"Old Reliable"—and their appreciation of his care for their welfare is yet more eloquently expressed by the other title they conferred on him—"Pap Thomas." Gen. Thomas has the glory, all but unique, of never having lost a battle when in independent command. When he served as a subordinate among other corps commanders he was ever the central figure. Though modest, above most men, he had yet a just appreciation of the value of his services, and when friends referred in his presence to the insufficient recognition these received he was wont simply to answer: "History will do me justice." Standing high among the noblest sons of the noble State of Virginia, his patriotism was not limited to the boundaries of State or section. His services to the cause of the Union were rendered chiefly elsewhere, and his fame is the inheritance of the undivided country which he helped to save.

(J. H.)

THOMPSON, JOSEPH PARRISH (1819-1879), preacher and author, was born at Philadelphia, Aug. 7, 1819. He graduated at Yale College in 1838, and was ordained pastor of a Congregational church at New Haven in 1840. His literary activity led him to join in founding the *New Englander*, a monthly magazine, in 1843, and afterwards the *Independent*, in 1848, at New York. He had been called to this city in 1845, and in the Broadway Tabernacle he gathered a large and influential congregation. With tongue and pen he was diligent in promoting religious and benevolent enterprises. On a visit to Egypt in 1853 he became interested in the study of its monuments, and when in 1871, worn out with the incessant demands on his time and strength, he was compelled by ill health to resign his charge, he removed to Berlin to pursue his archaeological investigations. But some of his most important public work was done in this new field of activity, where he obtained great favor with sovereigns and statesmen. His *Church and State in the United States* (1873) diffused effectively in Europe the American idea of religious liberty. In 1878 the Berlin Congress, through his influence, inserted a clause in its treaty favoring this idea. The Evangelical Alliance found in him one of its strongest supporters. In various parts of Europe he delivered lectures which developed and explained American ideas. Exhausted with his multifarious labors, he died at Berlin, Sept. 20, 1879. His books and other publications but partly reveal his ability and range. Besides some biographies he had published *Views of Egypt* (1854); *Love and Penalty* (1860); *Christianity and Emancipation* (1863); *Holy Comforter* (1866); *Theology of Christ* (1870); *Life of Christ* (1875).

THOMPSON, ROBERT ELLIS, economist and prominent defender of the protective tariff system, was born near Lurgan, Ireland, in April, 1844. His family emigrated to America in 1857, settling in Philadelphia. He graduated at the University of Pennsylvania in 1865, and, having studied theology, was ordained in the Reformed Presbyterian Church (N. S.) in 1873, but entered the Presbyterian Church in 1879. He had been assistant editor of the *American Presbyterian* from 1866 to 1870. He had returned to the University of Pennsylvania in 1868 as instructor in mathematics and Latin, and has since remained in connection with it, being made assistant professor of mathematics in 1870, professor of social science in 1874, and John Welsh Centennial professor of history in 1881. From the University he received in 1886 the degree of D. D. Prof. Thompson was editor of the *Fenn Monthly* from 1868 till 1879, and since that time chief editorial writer for the *American*, a political and literary weekly. He has also contributed largely to other periodicals on religious, political, educational, historical, and economical topics. He has delivered courses of lectures in elucidation and defence of the American protective system in Harvard, Yale, Williams, Amherst, and

other colleges. He has published *Social Science and National Economy* (1875), the third edition of which was revised under the title *Political Economy* (1883). His lectures before Harvard University were published under the title *Protection to Home Industry* (1886). He was the original editor-in-chief of this *Supplement*, but after two volumes had been prepared the work passed into other hands.

THOMSON, CHARLES (1729–1824), secretary of the Continental Congress, was born at Maghera, near Londonderry, Ireland, Nov. 29, 1729. With his family he sailed for America in 1741, but his father died on the voyage. He was taught by Rev. Francis Alison, at Thunder Hill, Md., and became a teacher first at Newcastle, afterward at Philadelphia. Through the friendship of Franklin and other influential men he was employed in negotiating treaties with the Indians, and the tribe of the Delawares adopted him as the "Truth-teller." He was engaged in mercantile business for some years, and was secretary of many literary and patriotic societies. Hence when the first Continental Congress met in Carpenters' Hall, Philadelphia, Sept. 5, 1774, they readily chose him as secretary, and he retained this position in each successive Congress until the adoption of the Federal Constitution in 1789. Then he was commissioned to notify Gen. Washington of his election to the Presidency, but declined any further public service. He spent many years in translating the Bible into English, using the Septuagint for the Old Testament. After his version was published in 1808 (4 vols.), he prepared from it a *Synopsis of the Four Evangelists* (1813). He died at Lower Merion, Pa., Aug. 16, 1824.

THOMSON, WILLIAM, Archbishop of York, England, was born at Whitehaven, Cumberland, Feb. 11, 1819. He passed from Shrewsbury School to Queen's College, Oxford, where he was in succession scholar, fellow, dean, bursar, tutor, and provost. Graduating in 1840, he was ordained deacon 1842, and priest 1843. After four years' parish work at Guildford and Cud-desden, he returned to his college as tutor, was appointed select preacher at Oxford 1848 and 1856, and provost 1855. In the same year he accepted the crown living of All Souls, Marylebone, and contributed to the *Oxford Essays*. In 1858 he became preacher at Lincoln's Inn, and in 1859 one of her Majesty's chaplains. Lord Palmerston procured his appointment to the see of Gloucester and Bristol in December, 1861, whence he was translated to York a year later, and enthroned Feb. 24, 1863, succeeding Dr. Longley. He has been active in educational and ecclesiastical reforms, had charge of the Public Worship Regulation Act in the House of Lords, and procured the appointment of a royal commission on church patronage. He is president of the Palestine Exploration Fund, a member of the Royal and Geographical Societies, a lord of the privy council, governor of the Charter-house and of King's College, London. He has been examiner in divinity at Oxford and in logic and mental science to the Society of Arts. Eminent as a scholar and metaphysician, he has published *An Outline of the Necessary Laws of Thought* (1842), largely used in England and America as a text-book on logic; *The Atoning Work of Christ Viewed in Relation to Some Current Theories* (The Bampton Lectures), 1853; *Sermons Preached in Lincoln's Inn Chapel* (1861); and *The Limits of Philosophical Enquiry* (1869), besides many charges, discourses, and contributions to Smith's *Dictionary of the Bible* and other works. He edited *Aids to Faith* (1861), a reply to *Essays and Reviews*, and projected *The Speaker's Commentary*. As archbishop of York he has an income of £10,000 and the patronage of 96 livings.

THOMSON, SIR WILLIAM, British mathematician and physicist, was born at Belfast in June, 1824. His father, James Thomson, LL.D., was then lecturer on mathematics in the Royal Academical Institute in Belfast, but afterwards removed to Glasgow, having been

appointed professor in the University of that city. The son was educated in that institution and at Peterhouse, Cambridge, where he graduated in 1845 and became a fellow. In 1846 he was made professor of natural philosophy at Glasgow, and has since retained that post. He was the editor of the *Cambridge and Dublin Mathematical Journal* from 1846 to 1853, and to it contributed valuable papers. He gave especial attention to electrical science, and invented several beautiful and delicate machines for investigating atmospheric electricity. Among his other inventions are the mirror galvanometer and the siphon-recorder, which proved of great service in submarine telegraphy. On the successful completion of the Atlantic cable in 1866, to which he had greatly contributed, he received the honor of knighthood. He also received the degree of LL.D. from the Universities of Dublin, Cambridge, and Edinburgh, and that of D.C.L. from Oxford. In 1871 he was chosen to preside at the meeting of the British Association in Edinburgh, and in 1881 was president of the section of mathematics at the meeting of the association in York. He has also received many marks of honor from foreign societies and academies. His *Mathematical and Physical Papers* were collected in a volume published at Cambridge in 1882.

THOMSON, WILLIAM MCCLURE, missionary, was born at Springfield, near Cincinnati, Dec. 31, 1806. He graduated at Miami University in 1826, studied theology at Princeton, and was ordained as an evangelist in 1831. He was sent as missionary to Syria in 1833, and labored there until 1876 with two intervals of rest, in which he returned to the United States. He is best known as the author of *The Land and the Book* (2 vols., 1859), in which in a conversational method vivid illustrations of the Bible are drawn from the scenes, manners, and customs of Palestine. The work has been thoroughly revised and enlarged in three volumes, *Southern Palestine and Jerusalem* (1880), *Central Palestine and Phœnicia* (1882), *Lebanon, Damascus and Beyond Jordan* (1886). Dr. Thomson now resides in New York city.

THORNTON, MATTHEW (1714–1803), a signer of the Declaration of Independence, was born in Ireland in 1714. His father soon removed to Wiscasset, Maine, and thence to Worcester, Mass. The son became a physician and accompanied Sir William Pepperell's expedition to Louisburg. He was also active in militia affairs, and in 1775 was president of the New Hampshire Convention. This body was divided into two houses in 1776, and Thornton became speaker of the assembly. He was not elected to the Continental Congress until September, yet on his appearance in it in November he was allowed the honor of signing the engrossed copy of the Declaration. He continued to attend Congress until the end of 1777, and then returned to New Hampshire, where he was Judge of the Superior Court until 1782, and held other offices. He died June 24, 1803, while visiting his married daughter at Newburyport, Mass.

THORNWELL, JAMES HENLEY (1812–1862), Presbyterian theologian, was born in Marlborough district, S. C., Dec. 9, 1812. Most of his life was spent at Columbia, S. C., either at the South Carolina College, or in the Presbyterian Theological Seminary. In the former he graduated in 1831, and after a brief experience in teaching and as pastor of a church at Lancaster, S. C. (1835–8), he returned to be professor of logic and belles lettres. His service was interrupted by a pastorate of a year in Columbia (1840–1), and six months in Charleston (1851). After the former his position was changed to that of chaplain and professor of Christian evidences, and after the latter he was called to the presidency. In 1855 the Presbyterian synod appointed him professor of didactic and polemic theology in their seminary, and this position he held till his death at Charlotte, N. C., Aug. 1, 1862. He had twice visited Europe for the sake of his health. He was well versed in ancient

and modern literatures, eminently successful as an instructor, and the most prominent leader of the Southern Presbyterian Church. His views were set forth in the *Southern Quarterly Review*, which he founded and edited from 1855 to 1857. In politics he strictly followed John C. Calhoun, and in theology John Calvin. Rev. J. B. Adger edited his *Collected Writings* (2 vols., 1874) and Rev. B. M. Palmer, D. D., his *Life and Letters* (1875).

THURMAN, ALLEN GRANBERRY, statesman, was born Nov. 13, 1813, at Lynchburg, Va. His father, a minister of the Methodist Episcopal Church, removed to Chillicothe, Ohio, in 1819, and here Allen received an academical education. After some experience as a surveyor he studied law with his uncle, William Allen, afterwards governor of Ohio, and with Judge N. H. Swayze, afterwards a justice of the U. S. Supreme Court. He was admitted to the bar in 1835 and soon was active in both law and politics. In 1845 he was elected to Congress, and in 1851 to the Supreme Court of Ohio, of which he became chief-justice in 1854. His term expired in 1856 and he returned to practice at the bar. In 1867 he was Democratic candidate for governor but was defeated by Rutherford B. Hayes, although Thurman had exhibited remarkable power as a campaign-speaker. The Legislature, however, was largely Democratic and elected him to the U. S. Senate, which had then only eleven others of his party. James G. Blaine in his *Twenty Years of Congress* pronounces Thurman then "the foremost man of his party in the nation." As such he vigorously supported the restoration of the government of the Southern States to the native whites. He stood firmly for the maintenance of gold and silver as the currency of the country, and resisted the Greenback movement. He opposed Chinese immigration and sought to maintain the control of the general government over the Pacific railroads. In 1881 his term as Senator expired, but Garfield, who had been chosen by the Legislature to succeed him, having been subsequently elected President, showed his friendly regard for Thurman by appointing him a delegate to the international monetary conference at Paris. Thirteen nations were represented, and the conference recommended the remonetizing of silver, but the disinclination of the English government prevented definite action on the part of any. After a tour through Europe Thurman returned to the United States and was soon active in his profession. In 1885 he was retained to assist government counsel in the suit against the Bell Telephone Co., but the cases were decided against the government. In some Democratic national conventions Thurman had been suggested as Presidential nominee and in 1876 he was a prominent candidate. In the convention of 1884 he received 88 votes on the first ballot. In 1888 a movement was started a few days before the meeting of the convention at St. Louis to name him for second place on the ticket, the first being accorded to Pres. Cleveland. When the convention met the proposal received general approval and he was nominated on the first ballot. Mr. Thurman, in spite of his age, exerted himself gallantly in the canvass, but his ticket was defeated by a decisive vote.

THURSTON, ROBERT HENRY, engineer, was born at Providence, R. I., Oct. 25, 1839. His father, Robert L. Thurston (1800-1873), was a successful builder of steam-engines. The son graduated at Brown University in 1859 and was engaged in his father's business until 1861, when he entered the navy as officer of engineers. He served in the North and South Atlantic squadrons throughout the war. He was then made assistant professor of physics in the U. S. Naval Academy. In 1870 he went to Europe to study iron-manufacture and on his return was appointed professor of mechanical engineering in the Stevens Institute, Hoboken, N. J. In 1873 he was a member of the U. S. scientific commission to the Vienna Exhibition, and edited the *Report of the commissioners*,

besides publishing his own *Report on Machinery and Manufactures* (5 vols., 1875-6). He was a member of the U. S. commission on steam-boiler explosions. In 1885 he was made director of Sibley College, or school of mechanical engineering and the mechanic arts, in connection with Cornell University, Ithaca, N. Y. Prof. Thurston has invented numerous improvements in mechanical devices. His many papers on scientific and technical topics have been published in both European and American journals. His *History of the Steam-Engine* is the standard work on the subject.

TIFFIN, a city of Ohio, county-seat of Seneca co., is on the Sandusky River, 34 miles S. W. of Sandusky, on the Cincinnati, Sandusky, and Cleveland Railroad and two other railroads. It has a court-house, 2 national banks, a savings bank, 16 churches, a convent, a high-school and other schools, and is the seat of Heidelberg College, which was founded in 1850 by the Reformed Church. Tiffin has 2 daily and 4 weekly newspapers. Its manufactures include agricultural implements, carriages, stoves, furniture, woollen goods, tiles, etc. Its population in 1880 was 7879.

TILLANDSIA, the generic name of a plant known by the various names of long moss, old man's beard, etc., belonging to the *Bromeliaceæ*, or pine-apple family, most of the members of which are epiphytes, or air-plants. *T. usneoides*, the common long moss, occurs abundantly in the Southern States, hanging in masses of long, dark, swaying fibres from the branches of the live-oak and other trees, and constituting a peculiar feature of Southern woodland scenery. There are in all eight species of *Tillandsia* in the United States, but the above named is the best known. Its stems are thread-like and pendulous, its leaves awl-shaped, its flowers sessile and small, the petals imbricated and tube-like below, spreading above, the seeds erect on long stalks. This plant is found in humid districts, from the Dismal Swamp southward, becoming very abundant in the Gulf States, and has considerable economic importance; its fibrous masses being extensively used for stuffing mattresses, cushions, bird-skins, etc. For these purposes it is one of the best of materials. The plant is also an ingredient in an ointment which is said to be useful for hæmorrhoids. In winter it is eaten by cattle. (C. M.)

TIME, STANDARD. The introduction of railroads and the invention of the telegraph, and the constant use of these modern facilities of intercourse, have forced upon the popular mind in America more than elsewhere attention to the fact of differences of local time, and given that fact a commercial bearing. Places on the same meridian have the same solar time, but places on different meridians, whether on the same parallel or not, differ in time according to their longitude. The proper management of railroads was early found to require the fixing of a standard of time, and each road undertook to establish a standard suited to its locality. But the great through lines of the United States, running chiefly east and west, found it difficult to secure such harmony among their different sections and connections as was absolutely necessary for safe and satisfactory working. In 1880 there were over fifty railroad standards of time used in the United States, and at the intersection of various roads these standards varied and conflicted in most perplexing ways. Nearly every railroad centre had two or three standards. Three were used in Chicago, five in Kansas City, six in St. Louis. The smaller cities readily adopted the time of the railroads which passed through them, though some took pride in having accurate solar time for the town-clock.

The establishment of the U. S. Signal Service, with its constant use of the telegraph at fixed times, brought before eminent scientists the practical consideration of the problem which was already annoying the railroad managers. Prof. Cleveland Abbé suggested the simple and ingenious plan which eventually,

with some modifications, was adopted by the railroad lines of the United States, and put in operation on Nov. 18, 1883. According to this system, this country, extending from 65° to 125° W. long., was divided into four time-sections, each of 15° of longitude, exactly equivalent to one hour. The objects aimed at by the railroad managers were to have as few standards as possible, yet so arrange them that the variation from mean solar time at any point within the section regulated by the standard should not exceed 30 minutes, and that the changes in the standard should take place at well-known points of departure, chiefly at the termini of the roads. The system adopted meets all of these requirements.

The 75th meridian west of Greenwich, which passes between New York and Philadelphia, gave an excellent starting-place. Its time was adopted for the District of Columbia by act of Congress approved March 13, 1884. According to the division of the country suggested by Prof. Abbe and adopted by the railroad companies, the First section, which is governed by the time of that meridian, includes all the territory between the Atlantic coast and Detroit, Pittsburg, Wheeling, Parkersburg, W. Va., Huntington, Bristol, Tenn., Augusta, Ga., and Charleston (the last being its most Southern point). The time of this section is called Eastern time, and it is marked by the dropping of time-balls at noon by the aid of the telegraph from the U. S. Naval Observatory and other observatories. The Second section includes all the territory from Detroit and the other western limits of the First section to Bismarck, Dakota, North Platte, Dodge City, etc. It includes nearly all the Mississippi Valley, the Gulf States, and the greater part of Georgia. Its time is governed by that of the 90th meridian, and is called Central time. It is one hour slower than Eastern time. The Third section extends from the western limit of the Central section to Helena, Montana, Ogden, Utah, and the western boundary of Arizona. Its time is that of the 105th meridian, and is called Mountain time. The Fourth section covers the rest of the country to the Pacific Ocean. The time is that of the 120th meridian, and is called Pacific time, being one hour slower than Mountain time.

One great advantage of this system is that the difference in time between prominent places is always an exact number of hours. At 12 noon in New York city the time at Chicago is 11 A. M.; at Denver 10 A. M.; at Portland, Oregon, 9 A. M.

It is probable that the system of standard time, successfully inaugurated in this country, will eventually be adopted throughout the world. An international congress of scientists was held in Washington in October, 1881, at which the meridian of Greenwich was recommended as a common prime meridian to be used in reckoning longitude throughout the world. When this has been adopted by the great commercial nations, it will be an easy step to have time reckoned from meridians exactly a certain number of hours west of that prime meridian, as is now done across the North American continent. (J. P. L.)

TIMOTHY. See PASTORAL EPISTLES.

TIMROD, HENRY (1829-1867), a Southern poet, was born at Charleston, S. C., Dec. 8, 1829, his father being a well-to-do bookbinder with poetic tastes, who died while Henry was in childhood. After some preliminary training in his native city, young Timrod entered the University of Georgia, but ill health compelled him to leave before finishing his course. The study of law proved uncongenial to his poetic nature and he became a teacher. His earlier poetical pieces, which appeared from about 1849 to 1853, in the *Southern Literary Magazine* and the short-lived *Russell's Magazine* (both of Charleston), attracted local notice. In 1850 he brought out a small volume of his poems through Ticknor & Fields of Boston. His feelings at this eventful period were intensely Southern, and on the outbreak of the civil strife he

became the Tyrtæus of the South. His lyrics, "A Cry to Arms" and "Carolina," as well as his addresses "To the Unknown Dead" and "To Spring," and his "Carmen Triumphale," breathe a spirit of almost feminine tenderness mingled with the fire of martial ardor. For some time Timrod was war-correspondent for the *Charleston Mercury*; in 1863 he removed to Columbia, S. C., where he became editor and part proprietor of *The South Carolinian*. This position promised a moderate competence, and in 1864 he married Miss Kate Goodwin. On the entrance of Sherman's army into Columbia, his office, printing-press, etc., were demolished and himself ruined. "My story for the last year" he wrote his friend Col. P. H. Hayne in March, 1866, "is beggary, starvation, death [he had lost a child], bitter grief, utter want." For a time he wrote editorials for *The Carolinian* of Charleston, and later was glad to act as temporary clerk to Gov. Orr. In 1867, owing to failing health, he on two occasions accepted the invitation of Col. Hayne to share his quaint home in the pine-woods of Georgia. Alarming hemorrhages drove him back to his home in Columbia, and he died there, Oct. 7, 1867. An enlarged edition of his poems and a sketch of his life by Paul H. Hayne appeared in 1873.

TIN. See METALS.

TITHES. See TABERNACLE.

TITUS. See PASTORAL EPISTLES.

TITUSVILLE, a city of Pennsylvania, in Crawford co., is on Oil Creek, 18 miles N. of Oil City, and on three railroads. It has a national bank and other banks, an opera-house, 10 churches, a high-school and other schools, 1 daily and 3 weekly newspapers. Its business prosperity has fluctuated with that of the oil region in which it is situated. While still principally engaged in this business it has also iron-works and barrel and wagon-factories. It has a good system of water-works. In 1880 its population was 9046.

TOAD, the common name of the batrachian family See Vol. XXIII. *Bufo*, sub-order *Anura*, or tailless Amphibians. The toads differ from the frogs, the other family of the *Anura*, in having the shoulder girdles in an embryonic state, and in being destitute of teeth, also in being more terrestrial in their habits. They have a thick and heavy body, covered with wart-like glands which secrete an acrid fluid, the fore and hind legs are nearly equal in length, the tongue is well developed and can be protruded with great rapidity in the capture of insects. They absorb moisture by the skin, which is cast off at intervals and swallowed. Their life in water is confined to the breeding season, ordinarily March and April, the remainder of their life being passed on land. They spend the winter in holes and crevices in a torpid state. The toad has been long regarded as venomous, though without warrant. Its glandular secretion may cause painful irritation of a tender or abraded skin, but can do no further harm, and the animal is entirely inoffensive and of great usefulness to man, as it destroys great numbers of insects injurious to vegetation. Toads have been known to live 35 or 40 years, and can survive for a long period without food and with little air, though the stories of their being able to live for years or centuries hermetically sealed in rocks and trees need confirmation. Experiments in this direction show that toads cannot long survive if deprived of air.

Toads are found all over the world, though most abundantly in the tropics. Ninety-two species are enumerated in the family, of which 77 belong to the typical genus *Bufo*. Of this genus the largest species is *B. maximus* of tropical America, of which individuals 8 inches long are often found. The United States has about 10 species of *Bufo*, of which the common eastern species is *B. lentiginosus*. This species occurs from Maine and Canada to the Mississippi Valley, and to the Gulf States, in which the typical form (with bony knobs or crests above the eyes) is found.

It is 2½ to 3 inches long, with a thick warty body, colored with spots of varying hue, size, and shape, the lower parts a dirty yellow. It is quicker in its movements than the common European toad. The variety found in the northerly region lacks the knobs over the eyes, and is classed as the sub-species *B. Americanus*. From Massachusetts to Canada still another variety is found, with an osseous ridge on the skull.

B. Americanus in the Middle States is a common inhabitant of gardens and other localities where insects abound. It is crepuscular in habit, its quiet but sudden movements being familiar to all. It is the earliest of the Batrachia to enliven spring with its note, as it rests on the water while depositing its spawn and continues to sing well into the summer. The eggs are deposited in a long, rope-like tube of transparent albumen, which gathers into a coil on the bottom of the water. When the young, after their transformation from the tadpole to the mature toad form, leave the water they make long journeys in the evening, hiding during the day. If rain falls they emerge from their hiding-places, thus giving rise to the supposition that they have been rained down to the earth.

A more localized and very small species, *B. quercinus*, ranges from North Carolina to Florida. The largest North American species is *B. boreas* of the Pacific region, which is sometimes nearly as large as *B. maximus*. In the upper Mississippi region is a small species, *B. dipterius*, which has two well-developed tarsal spurs for the purpose of excavating. This peculiarity, which is found in some other species of *Bufo*, is well developed in *Rhinophrynus dorsalis* of Mexico, whose remarkably strong shovel-like excavator enables it to rapidly make its way into the ground.

The members of the batrachian family, *Pelobatidae*, are nearly all subterranean in their habits. The American species of this family are exceedingly noisy at the time of depositing their eggs. *Scaphiopus holbrookii*, the hermit spade-foot toad, is common in the Middle States. Other species are found in the South-west, some of them with remarkably loud cries. Of the family *Hylidae*, or tree-toads, there are about 175 species, principally found in tropical America. The typical genus *Hyla* has 95 species, of which the common tree-toad of the United States is *H. versicolor*. This lays its eggs in the water on some fixed body, as an aquatic plant. The species of this family are noted for their loud and varied cries, the first note of spring in the United States being the shrill piping of *H. Pickeringii*, a swamp-dwelling species. This creature continues to sing into the fall, but not with the loudness and liveliness of his springtime note. The *Hylidae* are often brilliantly colored, and some of them are remarkable for their great changes of hue to accord with the surface on which they rest. *H. versicolor* when resting on a tree-trunk may be of a dull brown or a pale gray, representing a lichen; but when among tree-leaves becomes of a bright green. Those species which live among flowers and varied foliage are often very brilliant in their hues.

Another family of toads, the *Pipidae*, are tongueless, and differ in other respects greatly from those described. One species, *P. Americana*, the Surinam toad, has a remarkable habit, without counterpart in the order. The eggs are not laid in the water, but are received by the male, who deposits them on the back of the female. The skin thickens between the eggs thus deposited, till each is invested in a sort of sac, which is covered with a thin, gelatinous operculum. The young go through their metamorphoses in these sacs, the tail and branchiæ being absorbed while they are still in the egg. They emerge perfect frogs. This species is common in the dark corners of houses in Guiana, and is said to be eaten by the natives, in spite of its repulsive aspect. (C. M.)

TODD, JOHN (1800–1873), Congregationalist preacher and author, was born at Rutland, Vt., Oct. 9, 1800. His early life was a struggle with poverty

but he gained an education at Yale College, graduating in 1822, and then studied theology at Andover. He was pastor of a church at Groton, 1827–31, the congregation comprising many Unitarians. Afterwards he had charges at Northampton (1833–36), at Philadelphia (1836–42), and then at Pittsfield (1842–72). He was not only a strenuous upholder of Calvinism, but was active in the promotion of education. His own experience was largely embodied in his *Student's Manual* (1835), which had an immense circulation. Other books of a similar kind, such as *The Daughter at School* (1854), were less sought after. Dr. Todd assisted in founding Mount Holyoke Female Seminary, and was president of the Young Ladies' Institute at Pittsfield. Among his later books were *Mountain Gems* (1864), *Sunset Land* (1869), giving his impressions of California, and *Old-Fashioned Lives* (1870). In *Woman's Rights* (1867) he took a conservative view of the subject which provoked a reply by "Gail Hamilton" under the title *Woman's Wrongs*. Dr. Todd died at Pittsfield, Aug. 24, 1873. See *John Todd; the Story of his Life*, edited by his son, Rev. J. E. Todd (1876).

TODDHUNTER, ISAAC, English mathematician, was born at Rye, in 1820. His father was of Scotch descent and minister of a Dissenting congregation. The son was educated first at University College, London, then taught school at Wimbledon, and entered St. John's College, Cambridge. He graduated as senior wrangler in 1848, and became fellow, assistant tutor, and mathematical lecturer of his college. His school and college text-books on the various branches of mathematics have had extensive circulation in Great Britain and America. Besides these he has published *History of the Progress of the Calculus of Variations during the Nineteenth Century* (1861), and *History of the Mathematical Theories of Attraction and the Figure of the Earth from Newton to Laplace* (2 vols., 1873).

TOLEDO, a city of Ohio, county-seat of Lucas co., is on the Maumee River, 8 miles from Lake Erie. It is 92 miles W. of Cleveland and is an important railroad town. It has a good harbor and a channel 17 ft. deep, has been dredged through the Maumee Bay to the lake. Large elevators, with storage for 5,000,000 bushels, and the immense union railroad depot afford facilities for the shipment of grain and flour. There is also a large trade in lumber, live-stock, hides, wool, iron, and tobacco. The manufactures include carriages, wagons, pumps, steam-engines, agricultural implements, furniture and cabinet-ware, etc. There are also boat-yards and bridge-works. Toledo has a courthouse, 7 national banks, 6 other banks, 60 churches, a good system of public schools, several private schools, a free public library, 3 hospitals, 3 orphan asylums, and other charitable institutions. Three daily and 11 weekly newspapers are published here. The city is governed by a mayor, a board of aldermen, and a common council. It has a good supply of water and a paid fire department. Toledo was formed in 1836 by the union of two villages, and in 1880 it had attained a population of 50,137.

TOLSTOI, COUNT LYEFF NIKOLAIEVITCH, a Russian novelist and reformer, was born near Tula, Aug. 28, 1828. He is descended from Count Peter Tolstoi, a friend of Peter the Great. Among his contemporary relatives were Count Dmitri Tolstoi, minister of public instruction (1866–80), noted as an active agent of autocracy and enemy of liberty, and Count Alexis Tolstoi (1817–73), author of a trilogy of tragedies, *The Death of Ivan the Terrible*, *Czar Feodor*, and *Czar Boris*. Lyeff (or, as the name is commonly written in English, Lyof or Leo) was early orphaned, and was educated on his maternal estate of Jasnaja Polyana, except for two years, 1843–5, at the University of Kazan. In 1851 he went with a brother to the Caucasus and entered the army. There he wrote his first books, *The Cossacks* and *Childhood and Youth*.

An English version of the latter, by Malwida von Myenberg, was published at London, 1862, but attracted no especial attention; and though Tolstoi was an industrious writer from the start, his fame was for many years confined to his own country. At the beginning of the Crimean war, 1853, he was transferred to the Danube, and served on the staff of Prince Gortschakoff. In the defence of Sevastopol he commanded a battery: the painful experiences of that year are described with accurate detail in *Sevastopol in December, in May, and in August*. On the conclusion of peace he resigned his commission and made literature his chief employment, spending the summers on his estate and the winters in Moscow, where he married the daughter of a German physician. *War and Peace*, his longest book, appeared 1869. The next year he became a magistrate, and thenceforth lived chiefly in the country, striving for the instruction and improvement of his peasantry, teaching in the schools, and writing educational books. His most widely read novel, *Anna Karenina* (1876-77), bears witness to his varying interests, and indicates (perhaps unconsciously) his ripening disgust with society and the conventional modes of life. Soon after its appearance he wholly abandoned these and adopted the peasant's garb and humble labors, in pursuance of a scheme of socialistic philosophy, which he rather developed from within than learned from without. *My Religion* appeared in the *Nouvelle Revue*, and *Christ's Christianity* in an English translation in 1885. His peculiar views are set forth in these and others of his books, many of which, however, are not allowed to be printed in Russia, but circulate in MS. among his numerous admirers. His theology, at once highly mystical and profoundly rationalistic, has been explained by Miss Hapgood in the *Nation* for Sept. 27, 1888. It is understood to deny the divinity of Christ, the special inspiration of the Scriptures, the validity of prayer, and the immortality of the soul: yet he reveres Jesus as a supreme example of influence, and accepts literally the praise of poverty, the injunction of passive submission, and the enforcement of love to one's neighbor: these he obeys with unfashionable consistency and unfaltering zeal. Ecclesiastical authority he rejects, and would substitute "member of the Orthodox Greek Church" for "Pharisee." Nor will he enter or approve a dissenting sect, for he despises all organizations, and holds the spirit to be above them and independent of them. In an evil world absolute non-resistance, he holds, is alike the only policy for those who have or seek the light, and the only true obedience to gospel precepts. Circumstances prevent his carrying out his views fully, yet he has arranged his life in a manner which in any civilized land must provoke amazement, and cause his sanity to be questioned. He professes to regard his past life with loathing, as regulated by the false opinions and customs of society. Having tasted wealth, rank, warfare, pleasure, fame, he has found them vanity and vexation and been driven to seek eagerly for the peace of faith. To Mr. Kennan, the Siberian traveller, "he spoke slightly, almost contemptuously, of his works of fiction, and seemed to regard them as monuments of misdirected energy." (See *A Visit to Count Tolstoi*, in the *Century Magazine*, June, 1887.) He works at the shoemaker's bench and in the fields, and lives on terms of absolute democratic equality with peasants. Yet he writes as vigorously as ever tracts and stories, which are sermons, for the common people and their children; over them his influence is said to be powerful and widespread. A sort of Russian Buddha, the object nearest his heart is their improvement and the coming of that millennium in which men, relieved from the incubi of organized religion and government, shall dwell together in equality, peace, and mutual brotherly helpfulness. To contribute to this end is his one desire; and the government, which is swift to suppress an argument or a treatise, often allows the same revolutionary ideas

to appear in the guise of tales. A collection of Tolstoi's works in ten volumes appeared in 1880, but he has written much since then, and his bibliography is for the future historian.

Tolstoi's vogue in America has arisen since 1885. A writer in the *Nineteenth Century* said in 1879 that neither of his two greatest books seems likely to be translated into English. A version of *The Cossacks*, by Eugene Schuyler, when brought out in New York, attracted so little notice that the publishers determined to venture on no more of his. Since then, however, everything bearing his name has been welcomed, and a single house has issued some fifteen volumes of his writings, several of which are on the market in more than one version. The translators are Nathan Haskell Dole, Isabel F. Hapgood, Mrs. Alice Delano, and Huntington Smith: some are rendered from the original, others through the French. *War and Peace* and *Anna Karenina* are novels of great length; other volumes, as *A Russian Proprietor* and *The Long Exile*, are named from one of sundry short stories. The list includes *The Cossacks*; *Sevastopol*; *Katia*; *Ivan Ilyitch*; *The Invaders*; *In Pursuit of Happiness*; *What People Live by*; *Family Happiness*; *Childhood*, *Boyhood*, and *Youth*; *My Confession*; *My Religion*; *The Physiology of War*; *Napoleon and the Russian Campaign*; and *What to do: Thoughts Evoked by the Census of Moscow*.

Except perhaps Turgeneff, Tolstoi ranks as the first of Russian authors. He has his votaries and his opponents: Mr. W. D. Howells is unstinting in his praise, while Maurice Thompson derides him as an injurious writer and a "socialistic crank." His earlier and secular books illustrate with unsurpassed power the virtues and vices of the realistic school; those produced since he awoke to his mission, though often couched in the plainest language and dealing with the daily life of peasants, are loftily idealistic in spirit and conception. His genius is now generally conceded, and few would deny the purity of his motives and the nobleness of his aims; but as to the enjoyableness of his books, no less than the beneficial tendency of the larger and more ambitious ones, opinions differ widely. The photographic minuteness of *Anna Karenina*, the relentless bounding of human weakness into crime and misery, are dreary and depressing to some, while *War and Peace* has been described as a huge and confusedly overcrowded canvas. The reader may with justice complain that these romances are no more edifying, no more agreeable, than real life. With more open and compressed cynicism, *Ivan Ilyitch* sets forth the worthlessness of common purposes and cares. As to his later and shorter tales, most would admit that they often, in spite of their elaborately plebeian dress, have force, point, and beauty, with an elevated and poetic moral. Tolstoi himself would indignantly repudiate the dictum of an American critic, "The domain of his genius is fiction and not the bewildering muddlements of pseudo-philosophy." The best essays on Tolstoi are in French, by M. de Vogüé and E. Dupuy. (F. M. B.)

TOMATO, the *Lycopersicum esculentum*, a plant belonging to the *Solanaceæ*, or night-shade family. There are numerous species of the genus, all of South American origin, though the esculent tomato is now grown widely throughout the world. It is cultivated for its fruit, which is a very important article of diet, though until recent years supposed to be uneatable. The tomato was introduced into England in 1596, but for many years was grown only as an ornamental plant or for medicinal purposes. It was known as love-apple, which name is still given it in France and Italy. It was first used as a vegetable in Italy, and soon afterwards in France and England, though it has been in general use for this purpose less than fifty years. It needs warm suns, and does not ripen to perfection in England, though it is grown there for market under glass. As at present used it is one of

the most important of our garden products. It is easily managed, even by inexperienced hands, and hundreds of acres are now planted with it in the vicinity of all our large cities.

The tomato plant has a weak stem of about 4 ft. in length, which is apt to trail or become prostrate. The leaves are irregular pinnate with large leaflets, the stem and leaves being clothed with soft viscid hairs of a strong, unpleasant odor and a somewhat resinous substance which leaves a stain. It bears racemose clusters of yellow flowers, its fruit being a 2- or 3-celled berry, though there are numerous cells in the cultivated varieties. Under cultivation the fruit varies greatly in color and size, the plant being highly plastic, though it is possible that the cultivated forms may represent several species. Half a century ago this plant was raised only as a curiosity, or as an ornament from its red fruit, but it is now one of the most popular and useful of vegetables. It ripens after plucking, and hence can be picked green and transported long distances, our northern cities being supplied from Florida and the Bermudas and gradually up the coast before the fruit ripens in their own vicinity. It is used in numerous ways, eaten raw as a salad, stewed, baked, broiled and in soups, stews, and sauces. Tomato cat-soup is a favorite relish, and vast quantities of tomatoes are put up for winter use by canning and preserving.

To produce early crops the seed is sown in hot-beds or forcing-pits some ten weeks before planting in the open air. In the Middle States this is done about the first week in March, transplanting being done in middle May. The plants are placed in light sandy soil, in hills 3 ft. apart, and well manured. The yield under careful cultivation is about 400 bushels to the acre, the average market price being about 75 cents per bushel. This seems profitable; yet there is much expense and labor needed in the forcing processes necessary for an early crop. In the South, where convenient to shipping, the raising of tomatoes for the Northern market is a very remunerative industry. In some localities thousands of acres of tomatoes are raised by farmers under contract for canning purposes. These often sell as low as 30 cents per bushel, but this will pay on suitable land better than most farm crops, there being no need to plant early for this purpose.

Of the many varieties of tomatoes now in the market, among the leading ones in the vicinity of New York are the Mikado, Arme, Paragon, Perfection, Trophy, Red and Yellow Plum, General Grant, Hathaway's Excelsior, and Canada Victor. Elsewhere other varieties are more prominent. The Trophy has been in favor for many years, and is of unsurpassed size, flavor, and productiveness. Earlier and smoother varieties are now raised, though there has been no improvement in quality of varieties for twenty years past, and all further improvements seem likely to be in smoothness and solidity. The tomato is a plant which requires a high temperature to ripen its fruit, its time of ripening being May in Georgia, June in Virginia, July in Delaware, and August in New Jersey and New York. As a winter vegetable, in its canned state, it has hardly an equal among vegetable articles of diet, many millions of cans being annually used.

TOMPKINS, DANIEL D. (1774-1825), vice-president of the United States, was born at Scarsdale, N. Y., June 21, 1774. He graduated at Columbia College in 1795, and was admitted to the bar in 1797. He was elected to the Legislature in 1801, and took part in the revision of the State constitution. Elected to Congress in 1804, he resigned to become an associate justice of the N. Y. supreme court. In 1806 he was chosen governor of the State, and during his tenure of this office he gave effective support to the war policy of the national administration in 1812. At a later period the incomplete and confused record of his financial transactions at this time were used to injure his reputation, and prove him a debtor to the State,

though the contrary was the fact. His opposition to banks was conspicuously shown by his proroguing the Legislature for ten months to prevent the Bank of America from being established in the city of New York. The bank, however, finally obtained its charter. In 1816 he was elected vice-president on the ticket with Monroe, and before leaving the governor's chair he recommended the passage of an act abolishing slavery in the State of New York. This was done, the act taking effect in July, 1827. Tompkins was re-elected with Monroe, and at the close of his term retired to Staten Island, where he died June 11, 1825.

TOOMBS, ROBERT (1810-1885), Southern statesman and orator, was born at Washington, Wilkes co., Ga., July 2, 1810. He was educated at the University of Georgia and at Union College, N. Y., and studied law in the University of Virginia. He began the practice of law in 1831, and was captain of a company of volunteers in the Creek war in 1836. He was then elected to the State Legislature, and in 1844 he was elected to Congress, where he became a prominent representative of the Whig party. After eight years' service in the lower house he entered the Senate, being now most aggressive in demands for national recognition and support of slavery. After the election of Pres. Lincoln he urged forward the movement for secession in Georgia, and even when the Union party, headed by A. H. Stephens, elected a majority of delegates to the State convention, Toombs succeeded in bringing about the passage of an ordinance of secession Jan. 17, 1861. Toombs then withdrew from the Senate with a threatening speech, which the Senate some weeks later answered by a resolution expelling him. Meantime he had been active in the Confederate Congress at Montgomery, Ala., and was a candidate for the presidency of the new Confederacy. Jefferson Davis, however, was chosen, and Toombs was made secretary of state. The position was not to his liking, and he obtained a commission as a brigadier-general. Though his unwillingness to obey orders rendered him troublesome, he stayed with the army in Virginia until the end of 1862, and then returned to Georgia, where he had command of State troops. At the close of the war he refused to acknowledge the sovereignty of the United States, and went to Europe by way of Cuba. He returned, however, in 1867, and resumed his law practice, but proudly declared himself an "unrepentant rebel." A man of massive frame, he claimed from all he met recognition of his physical and intellectual superiority. This granted, he showed himself patronizing and genial, but if denied, he was arrogant and blustering. He was a kind master to his slaves; he would permit no inn near his residence—"Liberty Hall"—but welcomed there any stranger who visited the neighborhood. Numerous anecdotes and sayings attest his domineering character in the Senate, but in the history of the Confederacy he left little impression. He died at Washington, Ga., Dec. 25, 1885.

TOPEKA, the capital of Kansas, and county-seat of Shawnee co., is on the Kansas River, N. lat. 39° 3', W. long. 95° 40', and 66 miles west of Kansas City. Four railroads, the Union Pacific, the Chicago, Kansas, and Nebraska, the Missouri Pacific, and the Atchison, Topeka, and Santa Fé, furnish abundant facilities for communication and trade with all parts of the Union. The city is also well supplied with street railways. It has a handsome capitol, 2 opera-houses, 4 hotels, 4 national banks, 3 other banks, 4 daily and over 20 weekly newspapers. There are 17 school-buildings, whose property is valued at \$300,000, 2 business colleges, a Catholic seminary, Washburn College (Congregational), Bethany College for young ladies (Episcopal). There are 45 churches, comprising nearly every religious denomination, and some possessing fine edifices. Two bishops—Episcopal and Methodist—have their residence here. The Prohibition law is enforced and generally approved. Near the city are the State Asylum for the Insane and the State Reform School. Besides the machine-shops

of the Santa Fé Railroad, the chief industrial works are 9 flouring-mills, whose yearly output is 400,000 barrels. There are also 3 iron-foundries, 2 packing-houses, and factories producing starch, vinegar, clothing, harness, cigars, tents, wheels, windmills, and agricultural implements. The city is well laid out with wide, shady, well-paved streets, and handsome residences. It has excellent sewerage, an electric-light and telephone system, gas- and water-works. Topeka was settled in 1854 and incorporated in 1858. Its early history is closely connected with the settlement of Kansas and its admission into the Union. Its population in 1880 was 15,452, but it is estimated in 1888 to be 40,000. Its assessed valuation in 1887 was \$7,270,017, the true value being thrice as much.

TORBERT, ALFRED T. A., general, was born in Delaware in July, 1833. He graduated at West Point in 1855, and was appointed brevet second-lieutenant of infantry. He served in Texas and Florida, and took part in the Utah expedition of 1857-58. When the civil war broke out he was employed in mustering New Jersey volunteers into service, and in September was made colonel of the First regiment N. J. volunteers. With his command he participated in McClellan's Peninsular campaign, and in August, 1862, he was assigned to the command of a brigade. He fought in the second battle of Bull Run, and was wounded at South Mountain. He was then made brigadier-general of volunteers, but was unable to serve until June, 1863, when he returned to his brigade in the Sixth corps in time to fight at Gettysburg. In 1864, while Gen. Sheridan conducted a raid on Richmond, Gen. Torbert commanded the cavalry which remained with Gen. Grant, and afterwards led the First division in several actions, including the battle of Cold Harbor. Gen. Torbert was now made chief of cavalry of the Middle military division, and was engaged in all the operations in the Shenandoah Valley. In April, 1865, he was made commander of the Army of the Shenandoah, and afterwards had charge of various districts, until he was mustered out of the volunteer service in January, 1866. In October of that year he resigned from the regular army, in which his actual rank was only captain, though he had brevet rank as major-general. He was sent as U. S. minister to Salvador in 1869, as consul-general to Havana in 1871, and to Paris in 1874.

TORNADO. There are two well-marked species of gyrotory storms—the cyclone, in which the wind moves mainly in a horizontal direction and covers an extensive area, and the tornado, in which the movement is principally vertical and the ground area of the storm very small. These two kinds of storm are connected by no intermediate gradations, and seem distinct in character and origin. The tornado, however, is connected with a series of less violent gyrations, ranging from the waterspout of the ocean and the sand-storm of the desert down to the little dust-whirl which is so ordinary a phenomenon in our streets. The violent form of whirl known as the tornado occurs more frequently and disastrously in the United States than in any other region of the earth, and is particularly prevalent in the valley of the Mississippi, where severe examples are of annual occurrence, and the loss of life and property often extensive.

The tornado, which apparently has its origin in the clouds at no great distance above the earth, presents the appearance of a vast cloud funnel, visibly descending from the layer of cloud in which it originates until it reaches the earth, where it draws up everything that lies in its path into its swift revolving vortex. Its cloud-like appearance is due to the condensation of moisture in the warm and compressed air of the wind-whirl, into which the adjoining air is drawn with great force and caused to revolve with extraordinary violence, the motion being an upward spiral, with a partial vacuum in its centre. The path of the tornado is always very narrow, averaging less than a quarter-mile in width, the greatest violence being in its

central region. In this region everything that is touched is destroyed; houses unroofed or torn to pieces, and their fragments thrown long distances; great trees twisted off like reeds; such weights as locomotives lifted and hurled aside, and a power displayed which it is difficult to appreciate. The whirling motion is indicated by the twisting of trees and the turning round of buildings which have been lifted from their foundations, while the mode in which the walls of houses occasionally seem to burst outward in all directions appears the work of a vacuum in the passing centre of the whirl.

The tornado cloud never seems to reach to a great height, but becomes lost in the broad layer of cloud from which it depends. It sways to and fro, like a dangling whip, as it moves rapidly along its path of destruction, the end occasionally rising from the ground to descend farther on. When thus raised it seems somewhat pointed at bottom, and though the surface wind is still severe, little harm is done. The path of greatest violence of the tornado is very narrow, while the time of passage of its centre over any spot is less than a minute, sometimes but a few seconds. It seems to strike everything within its reach a single blow, like that of a gigantic hammer which destroys whatever it touches. The wind pressure of the tornado has been estimated from its effects to vary from 18 to 112 pounds to the square foot, and the velocity of the wind to be sometimes as much as 2000 miles per hour.

Definite scientific observations of tornado phenomena have been confined to a few years past, this work having been taken up by Lieut. John P. Finley, of the Signal Service Bureau, who several years ago organized a system of regular observations which have added greatly to our knowledge of the subject. He has learned so much concerning the tornado conditions, in fact, as to be able to predict, with some degree of accuracy, the probable appearance of such storms within the settled regions of the country. In furtherance of this project he has sent blanks to competent persons throughout the tornado region, desiring them to describe the character and peculiarities of every tornado that came under their observation, and in this manner obtained a large sum of statistics. As a result of his studies on the subject it may be stated that of 38 predictions made by him in April and June, 1884, that tornadoes would occur, 18 were verified, and of 19 in June and July, 1885, 15 were verified. In all cases violent storms occurred, either tornadoes, fierce gales, or hail-storms.

His predictions are based on the following observed facts. Tornadoes are found to be always associated with cyclones, and always to make their appearance in the south-east quadrant of the cyclone, or south-east of a moving centre of low barometric pressure, while their tracks conform closely to the direction of the main storm. Their place of occurrence, however, is several hundred miles distant from the centre of the cyclone. The favorable climatic conditions are an elevation of temperature of from 15 to 50° above the normal, and an excessive humidity, with abnormal conditions of wind direction and cloud formation and movement. The average number of tornadoes which annually occur in the region east of the Rocky Mountains is over 100. In 1884 there were 172. Of 600 recorded occurrences from 1794 to 1881, 304 moved from south-west to north-east. As a general rule about 80 per cent. of them move in this direction, and about 10 per cent. from north-west to south-east. The average width of path is 1085 feet, and of velocity 30 miles an hour, though the velocity may vary from 1 to 150 miles per hour. The cloud is nearly always funnel-shaped, varying from the hour-glass to the conical and the inverted funnel forms. The direction of the whirl is almost invariably opposite to that of the movement of a clock-hand, in this respect agreeing with the gyration of the cyclone. Tornadoes move parallel to the pro-

gressive storm by whose side they are developed, keeping their average distance of several hundred miles from its centre. They occur most frequently in the months of May, April, June, and July, in the order given, and from 3.30 to 5 P. M., immediately after the warmest part of the day, and when warm ascending currents are most likely to meet cool descending currents.

In the United States 3000 persons have been killed and as many injured by these storms, while the loss of property reaches scores of millions of dollars. They occur most frequently in the States bordering the northern Mississippi and the lower Missouri. Here the warm and very moist winds from the Gulf meet with currents of cold air from the north, exceedingly unstable atmospheric conditions being produced. They seldom or never occur west of the 100th meridian, a region unvisited by severe cyclones. Of the various tornadoes on record the most remarkable series was that of Feb. 9, 1884. On that day, after 10 A. M., more than 60 tornadoes occurred in the States between Illinois and Virginia on the north, and Mississippi and Georgia on the south, at distances of from 500 to 2,000 miles from the cyclone centre. The damage was excessive; more than 10,000 buildings were destroyed, 800 persons killed, and 2500 wounded.

Thunder and hail-storms occur in the same advance quadrant of the cyclone with the tornado, and possibly all arise from the same general conditions. These storms are doubtless all due to the effort at equilibration in very unstable atmospheric conditions. The tornado is always preceded by warm and humid southerly winds, and followed by cold northerly ones. The preceding atmosphere is, in fact, saturated with vapor, its abnormally high temperature increasing its capacity in this respect. There is probably a very rapid diminution of temperature with altitude, and undoubtedly the large temperature gradients vertically, and the marked contrast of vapor conditions, have much to do with the development of the tornado, which is naturally propagated along the line and in the direction in which the unstable condition of equilibrium prevails. The gyration noticeably forms in the upper air, where the winds attain a much greater velocity than on the surface, and gradually descends. The warmth and high vapor conditions of the southern and eastern regions of the cyclone are doubtless the reason that tornadoes appear there and not in the northern and western regions, where the air is comparatively dry and cold, and the equilibrium of the atmosphere much less disturbed.

Several theories as to the immediate cause of tornadoes have been advanced. Guyot ascribed them to the meeting of opposite winds of different temperatures in the upper atmosphere. According to a more recent theory, the tornado is preceded by the formation of a surface layer of abnormally warm air, above which extends a layer of much cooler air. The former, in its effort to ascend, pierces the latter at some point, and rushes upward in a spiral whirl or eddy which quickly draws the surrounding warm air into its vortex. This theory is based on the analogy of the behavior of water under circumstances similar to those assumed, as, to adduce a familiar instance, when the stopper is pulled from the escape-pipe of a bath-tub. In this case the water rushes from all sides towards the vent, and eddies round in a descending spiral as it passes downward through the pipe, a water vacuum existing in the centre of the eddy. The analogy to the tornado seems very close, yet this theory, though supported by some eminent meteorologists, is hardly in accordance with the facts. Instead of the preceding calm conditions which it seems to require, the tornado is preceded by strong winds. Nor does it offer any explanation of the cold north winds which follow the tornado, nor of the rapid and somewhat regular progressive motion of the latter. It is in agreement with the water analogy, but hardly with the atmospheric conditions.

There are other water eddies, however, of more normal character, that of which we have spoken needing unusual conditions for its manifestation. The normal eddy requires moving water for its propagation, and never appears when this water moves steadily and regularly. But at the least disturbance of this regularity, eddies are generated, and increase in width and violence as the disturbance becomes greater. In short, the ordinary eddy is due to opposition to the movement of water currents, either from the meeting of two currents more or less opposed in direction, or from the impingement of a current on an unyielding obstacle and the hurling of the water back upon itself. The latter is the case in the tornado-like whirlpool at Niagara. In every case we have the meeting of two bodies of water which cannot pass each other, and whose progressive motion is converted into a whirl, while the accumulating waters can only escape downwards, so that the whirl is converted into a descending spiral.

This form of eddy appears to be the true analogue to the atmospheric eddy known by the various names of whirlwind, tornado, etc. In the latter case wind is always present, and apparently opposing winds. In the little dust-whirl of the streets this seems evident. It only appears during gusty winds, where the air currents frequently vary their direction, and it seems to indicate the meeting of two opposing puffs of wind, which break into an eddy as they meet, while the progressive motion of the whirl is due to the gradual meeting of the angularly opposed fronts of the currents. In this phenomena we probably have, on a small scale, what is repeated in the tornado on a large scale.

Before proceeding with the argument, however, a more particularized statement of tornado conditions is important. The disturbance, as already said, always begins in the upper air. Lieut. Maury, in 1882, attributed the tornado to an upper air current seen at times to move from the south-west at a speed of 100 miles per hour. Numerous descriptions show that the first tornado indication is a cloud to the northward, heavy, black, and comparatively slow in its southward movement. This is met by a light, rather smoky, and more rapid cloud from the south-west. These clouds, borne by their respective winds, rush together, violent conflicts of currents drive the clouds in every direction, up and down, round and round; clouds, like great sheets of white smoke, dash about in a frightful manner. Finally, a black, threatening mass descends slowly towards the earth, whirling violently, but still manifesting confusion in form. This soon gives place to the peculiar funnel-like shape, intensely black in appearance. As white clouds appear and are drawn into the vortex, the funnel trunk sways like an elastic column. Substances drawn up are seen flying in its centre, gradually rising, to be finally flung out near the top after the storm has progressed a mile or two. Dark masses of cloud shoot down the sides of the funnel, and are drawn into the vortex near the ground. At times the velocity appears to increase, and everything is torn to splinters. A peculiar hollow, rumbling, but very loud sound accompanies the storm.

This description of the genesis of a tornado, abbreviated from Prof. Eddy's paper in the *Popular Science Monthly*, is in accordance with the following description of the tornado of May 30, 1879, from the Signal Service Report:

"The cloud from which the funnel depended, seen at a distance of 8 miles, appeared to be in terrible commotion; in fact, while the hail was falling, a sort of tumbling in the clouds was noticed as they came up from the north-west and south-west, and about where they appeared to meet was the point from which the funnel was seen to descend. There was but one funnel at first, which was soon accompanied by several smaller ones. . . . Finally, one of them seemed to expand and extend downwards more steadily than the

others, resulting at length in what appeared to be their complete absorption."

These are typical examples of general tornado descriptions, all of which indicate wind opposition. Opposite winds seem always to prevail, probably in different strata of the atmosphere, the south wind usually, perhaps always, the lower. This warm and humid south wind naturally rises, while the cold north wind as naturally descends. Thus two strong and opposite air currents, which had been moving in different layers of the atmosphere, meet face to face. The result seems necessarily the same in air as in water, the formation of a vigorous eddy or vortex, whose energy depends upon that of its constituent winds. In this case the escape is upwards, and the descent of the eddy to the ground is probably a consequence of the effort of the winds to pass each other. The opposing air currents have widely extended fronts, more or less angularly inclined to each other, so that they come together gradually, like, to use a homely illustration, the meeting of the blades of shears. To this the progressive movement may be due. The vortex is generated at each successive meeting point of the winds, and vanishes in the rear as it forms in front. Its speed of progression indicates that of meeting of the angular wind fronts, and depends on the width of the angle, while its irregularities are doubtless due to the variations of speed and direction in the winds to which it owes its origin. The final prevalence of the north wind at the surface seems to indicate a reversal of position in the two air currents, the north having descended to a lower, the south ascended to an upper stratum of the atmosphere, so that they once more pass without opposition.

Gen. Greeley's list of destructive tornadoes is given in part in the following table, some of the less destructive being omitted:

State.	Date.	Loss			
		Killed.	Injured.	Houses.	Value.
Miss.	May 7, 1840.	317	109	----	\$1,260,000
"	June 16, 1842.	500			
Conn.	Aug. 9, 1878.	34	28	----	2,000,000
Mo.	April 18, 1880.	101	600	---	1,000,000
Iowa.	June 17, 1882.	100	300	260	1,000,000
Miss.	April 22, 1883.	51	200	100	300,000
Wis.	May 18, 1883.	16	100	52	175,000
Minn.	Aug. 21, 1883.	26	80	400	700,000
Ark.	Nov. 21, 1883.	5	162	60	300,000
N. C.	Feb. 19, 1884.	18	125	55	
Dak.	July 28, 1884.	15	18	100	
Wis.	Sept. 9, 1884.	6	75	305	4,000,000
N. J.	Aug. 3, 1885.	6	100	500	500,000
Ohio.	Sept. 8, 1885.	6	100	300	500,000
Minn.	April 14, 1886.	74	136	138	385,000
Ohio.	May 12, 1886.	57	----	85	
Kan.	April 21, 1887.	20	237	330	1,000,000

Many of these tornadoes extended through several States, that of April 14, 1886, for instance, travel 350 miles—from Council Bluffs to Sauk Rapids, Minn., which town it destroyed. That of April 18, 1880, utterly wrecked the town of Marshfield, Mo. Many other towns and villages have been partly or wholly destroyed, and it seems evident that, in the fuller settlement of the Mississippi Valley States, a greatly increased annual destruction may be expected from this source. The forests of that section often present great lanes of broken-down and torn-up trees, indicating the tracks of tornadoes in the past. As towns replace forest and cover the prairie lands, the danger will proportionately increase. The Atlantic States, while less frequently visited by this terrible agent of destruction, are by no means exempt. Several of the examples in the table given were in the East—that of August 3, 1885, passing through the city of Camden, N. J., where it made frightful havoc. A more recent disaster of this kind was that of January 9, 1889, in which a violent tornado struck the city of Reading, Pa., fortunately only on its outskirts, utterly wrecking a silk-mill and a railroad paint-shop, with a loss of 24

killed, 98 injured. This tornado passed over a considerable extent of country, but, by good fortune, struck no other town. What was probably an accompanying tornado passed over Western Pennsylvania on the same day, doing great damage in the oil-fields, blowing down the suspension bridge at Niagara, and wrecking an unfinished building at Pittsburg, with considerable loss of life. (C. M.)

TORTOISE, one of the names given to the *Testudinata*, or shell-bearing reptiles, which See Vol XXII. are known also by the common names p. 455 (p. 484 of turtle and terrapin. As at present Am. Rep.) used the tendency is to restrict the title of tortoise to the marine species, that of turtle to the land species, and that of terrapin to fresh water and coast species of the family *Emydida*. In the United States the name of terrapin is applied only to a few species of this family which are used for food. The United States has in all 42 or 43 species of tortoises, of which all, with the exception of the musk tortoises, are used to a greater or less extent for food, or for other economical purposes. Yet only a few species are in actual demand, including the marine green turtle, 2 or 3 species of soft-shelled turtles, the snapping turtle, the gopher or land-turtle, and 3 or 4 species of terrapin. Of the latter much the most highly prized is the diamond-back salt-water terrapin (*Malaclemys palustris*). This species is found in the salt marshes along the coast from Massachusetts to Texas and also in South America. The northern terrapin, however, are more delicate in flesh than those of the Gulf, and the principal market supply comes from Chesapeake Bay and the coast of the Carolinas. Egg Harbor, N. J., also furnishes some very fine ones.

The diamond-back terrapin is of small size, the under shell of the female averaging 6 or 7 ins. in length, its extreme length being 10 ins. The weight is 4 or 5 lbs., though in extreme cases 10 lbs. is reached. It has a very large head, with strong and cutting jaws, small eyes, and short and thick neck. The shell is oval, moderately convex, and of a dusky olive-green color, with darker concentric lines. The sternum, or lower shell, is yellow, with dusky concentric lines. This species is very shy and active, swims well, and runs with considerable speed on land. The males are smaller than the females, much less valued, and sell at a considerably lower price. The fishing season lasts from Oct. 1 to June 1, October and November being the best months. At this period the terrapin has buried itself deeply in the mud for its winter hibernation, and is very fat and juicy. It is easily found by a mound of mud raised above its hiding-place, and is taken in considerable quantities. The eggs, 25 to 100 in number, are laid in early spring. Females in egg are the most highly valued, the eggs being the tidbit of epicures. In their best season terrapin sell at from \$15 to \$36 and even \$50 per dozen, according to size. The males are used only in soups, and bring about \$3 per dozen. Many terrapins are caught in summer, and penned in "yards" till the market season. They are found to breed in captivity, and efforts have been made, with some success, to raise them from eggs laid under such circumstances. This is important, as the annual catch, never large, is steadily decreasing. Philadelphia is the principal market for terrapin, though large quantities are supplied to other seaboard cities, and many are sent to the cities of the interior.

There are from 15 to 20 species of fresh-water terrapins in the United States. These, formerly classed in the genus *Emys*, but now divided into several genera, differ from the land-turtles in having their feet more webbed and expanded, and the shell of the back more flattened. Three or four species of the genus *Pseudemys* are of marketable value. Of these the red-bellied terrapin, *P. rugosa*, is usually 10 or 11 ins. long. Its upper shell is of a dusky brown color, with blotches and lines of red; the lower shell is of a dusky

red hue. It dwells only in the Delaware and Susquehanna and the rivers of Chesapeake Bay. The flesh is very palatable, and it is gathered in considerable numbers for market, being largely substituted for the diamond-back in restaurants.

Yet more esteemed is the yellow-bellied terrapin, *P. scabra*, which is found in stagnant ponds from Virginia to Florida, and is abundant in the latitude of Charleston. It is about 12 ins. long, $7\frac{1}{2}$ wide, and 11 high, the upper shell being very convex, and deeply serrated behind. It is of blackish-brown hue, with radiating yellow lines and marks, the sternum being yellow. These species feed on small reptiles, fish, etc., and will eat vegetable food in captivity. Out of water they move more quickly than the land-turtles. Farther south occurs another species of value, the Mobilianer (*P. Mobiliensis*). This is the largest of the food species, the shell being often 14 to 16 ins. long by 10 wide, and $7\frac{1}{2}$ high. In color it is brownish, with yellow lines and bands, while the sternum is pale yellow. It is found in lakes and rivers from North Carolina to Western Louisiana, and up the Mississippi to Arkansas, and is very abundant in East Florida, especially in the St. John's River. The flesh is quite delicate, and is much esteemed in the Southern cities.

The chicken terrapin, *Chrysemys reticulata*, is about 9 by 5 in. in dimensions, the color of its upper shell being dark brown with a network of yellow lines, that of the lower yellow. Its long neck, as it swims with body hid and head extended, presents a snake-like appearance. It occurs from North Carolina to Louisiana, and is the most esteemed of the fresh-water terrapins. *C. picta*, a somewhat smaller species, is also valued as food.

Other species of tortoises are used as food in the United States. Of marine tortoises the only species of value is *Chelonia viridis*, the green turtle, which is used extensively as the basis of turtle soup. The Pacific coast has a related species, *C. virgata*. Of what are known as soft-shelled tortoises the United States has 6 species, belonging to 2 genera, which differ in length from 6 in. to 2 ft. or more, and in weight from 4 to 16 lbs. These occur in most of our lakes and rivers, from the Atlantic to the Rocky Mountains, and are easily taken by hook and line, as they bite greedily. Their flesh is a superior article of food, surpassing in delicacy, it is said, the green turtle. Their eggs also are considered excellent.

Of the snapping turtles there are two species, belonging to different genera. The northern species, *Chelydra serpentina*, is widely distributed, and is largely taken for food purposes. Its maximum weight is 20 to 30 lbs. The Southern species, known as the alligator turtle, weighs 50 or 60 lbs. and in extreme weight 100 lbs. It is spoken of very highly as a food species, some stating that it is more delicate than the green turtle, though this is doubtful. The gopher, the great land-turtle of the South, is also used to some extent as food. This species is 15 in. long and is so strong that it can move under a weight of 200 lbs. It lives in underground burrows in the sandy forests of the Gulf States. Even the little "box turtle," the familiar inmate of our fields and gardens, is occasionally eaten, and is said to be quite palatable when fat. (C. M.)

TOTTEN, JOSEPH GILBERT (1788-1864), chief-engineer U. S. A., was born at New Haven, Conn., Aug. 23, 1788. He graduated at West Point in 1805, and being commissioned second-lieutenant in the engineers' corps went as assistant to his uncle, Jared Mansfield, surveyor-general of Ohio. Although he resigned from the army he soon returned and was engaged in the construction of forts in New York harbor until the commencement of the war of 1812. Then he was made chief-engineer of the army on the Niagara frontier and fought at Queenstown. Afterwards he served at Lake Champlain and was brevetted lieutenant-colonel for his gallantry at the battle of Platts-

burg. In 1816 a Board of Engineers was formed to devise a system of coast defence, and in connection with this work Totten rendered most important service to his country. In 1819, when Gen. Simon Bernard was brought from France to give the benefit of his long experience in this branch of warfare, the other members of the board resigned, but Major Totten continued, and the reports prepared on harbor and coast defence were mostly from his pen. In 1825 Totten (now brevet colonel) began the construction of Fort Adams at Newport and was thus engaged for thirteen years. In 1831 Gen. Bernard retired and Totten had charge of the harbor defences east of New York. In 1838 he published *Hydraulic and Common Mortars*, giving the result of many experiments by himself and others. In the same year he was made chief-engineer with the rank of colonel, and removed to Washington. He continued to carry out his plans of coast defence until 1847, when he was called by Gen. Winfield Scott to take charge of the engineering operations in the siege of Vera Cruz. After the capture of the city he returned to Washington, having obtained the brevet of brigadier-general for his services. Besides his office work at Washington, he made a biennial tour of inspection, examining every detail of construction in the forts and other defences. He was also a member of the Light-House Board from its organization in 1852, and was actively connected with various scientific associations. When Gen. Scott was obliged to retire from the chief command of the army, he suggested Gen. Totten as his successor, but the latter declined on account of his own advanced age. He died at Washington, April 22, 1864, having received a brevet as major-general on the previous day. Among his *Reports* may be mentioned those on *National Defences* (1851) and *Ordnance* (1857). Although the fortifications to whose construction his energies were given have been proved insufficient owing to the vast changes in ordnance, there has been no system devised to take their place which meets universal approval.

TOURGEE, ALBION WINEGAR, author, was born at Williamsfield, Ohio, May 2, 1838. He prepared for college at Kingsville Academy and entered Rochester University as sophomore in 1859. He was one of the first to volunteer for service in the Union army, enlisting April 17, 1861, as a private in the Twenty-seventh N. Y. volunteers. He was wounded at the first battle of Bull Run and discharged, but the following year was commissioned first-lieutenant, by Gov. Tod, of Ohio, and recruited Company G, One-hundred-and-fifth Ohio V. I. He resigned his commission in 1864 on account of wounds and disease contracted in Salisbury and Libby prisons. He was married to Emma L. Kilbourne, of Conneaut, Ohio, in 1863, and at the close of the war settled in Greensboro, N. C., as lawyer and editor. He was a delegate to the Southern Loyalist Convention held in Philadelphia in 1866, and was a member of the committee that drew up the report on the condition of the Southern States. He was elected to the constitutional convention of North Carolina in 1868, and took so prominent a part in this body that the constitution then prepared is often called "Tourgee's constitution." He was appointed by this convention one of the three commissioners to codify the laws of the State. He was elected judge of the Superior Court in 1868, which office he held until the expiration of his term in 1874. He was also a member of the State constitutional convention of 1875. He is the author of the *N. C. Form Book*; *The N. C. Code with Notes*, and a *Digest of Cited Cases*. Besides these legal works he is the author of the following works of fiction: *Soinette* (1874; in later editions *A Royal Gentleman*); *Figs and Thistles* (1879), a romance partly founded on Pres. Garfield's army career; *A Fool's Errand* (1879), a work that attracted much attention and has been translated into several languages. It is a graphic exposure of the difficulties

which Northern men and women encountered in attempting to settle in the South after the war. To it was afterwards added an appendix, "The Invisible Empire." To the same class belong his *Bricks without Struc* (1880); *John Eric and Mamelon* (1882); *Hot Plushares* (1883); *An Appeal to Caesar* (1884); *Caesar* here denoting the sovereign American people; *The Veteran and his Pipe* (1886); *Button's Inn* (1887), a story relating to the early days of Mormonism in Ohio; *Black Ice and Letters to a King* (1888). From 1882 to 1884 Judge Tourgee was editor of *Our Continent*, a weekly magazine, published in Philadelphia. No man has contributed more to the political education of our people than Judge Tourgee. Original in method, fearless in expression, and graphic in style he has pressed home to the hearts and consciences of the American people the difficult political and social problems of his generation. His present residence is at Mayville, Chautauqua co., N. Y., where he employs himself solely in literary pursuits.

TRADE, BOARDS OF. These are combinations of merchants, manufacturers, and others to promote the interests of commerce, external and internal, and in every way to aid the industrial advancement of cities and nations. The first idea of concerted action for this purpose seems to be due to Cromwell, who in 1655 appointed his son Richard, many lords of his council, judges and gentlemen, and about twenty merchants of London, York, Newcastle, Yarmouth, Dover, etc., to meet and consider how the trade and navigation of the Commonwealth might be best promoted. After the Restoration, in 1660, Charles II. established a council of trade to control all the commercial interests of the nation, and afterwards instituted a Board of Trade and Plantations. This board, after being remodelled by William III., continued in existence till 1782, when it was abolished, and a new council for the regulation of trade affairs, on the plan still existing, was appointed Sept. 2, 1786. See **TRADE, BOARD OF**, in the *ENCYCLOPEDIA BRITANNICA*.

Apart from this governmental board, the merchants of many cities, both in Europe and in the United States, have organized civic Boards of Trade, or Chambers of Commerce as they are called in some cases, whose deliberations have taken a wide scope and proved of the utmost benefit to commercial interests at large. At their meetings every subject relating to the material interests of cities and nations is debated, the mature judgment of the members brought to bear on the problem, and resolutions taken in accordance with the opinions of those best adapted by their experience to offer wise and pertinent suggestions.

The earliest American movement in this direction was made April 5, 1768, on which date twenty merchants of New York organized themselves into the Chamber of Commerce of that city, for the expressed purpose of the promotion and encouragement of commerce, of adjusting disputes relative to trade and navigation, supporting industry, obtaining necessary legislation, and doing everything in their power in the interest of commerce. This association is still in existence, the only one dating from the last century with the exception of the New Haven Chamber of Commerce, organized in 1794. No similar institution was organized till 1833, when the Philadelphia Board of Trade was established, composed of persons interested in commerce, finance, manufacturing, and the mechanic arts; its object being the promotion of the trade of the city, the improvement of facilities for transportation, and the use of all proper measures for advancing the interests of the business community.

The idea thus instituted by the leading cities of the country was adopted by others in gradual succession: by Cincinnati in 1839, Buffalo in 1844, Chicago in 1848, Baltimore in 1849, San Francisco in 1850, Portland in 1853, Boston in 1854, Detroit in 1856, Milwaukee in 1858, St. Louis in 1866, and others of the smaller cities at various intermediate and later periods.

In 1868 a new idea was put into effect, in the formation of a National Board of Trade, composed of delegates from the associations of the several cities, the first meeting of which was held at Philadelphia in June of that year. It was composed of delegates from the following organizations: the Boards of Trade of Albany, Baltimore, Boston, Buffalo, Charleston, Cleveland, Denver, Detroit, Louisville, Newark, Oswego, Philadelphia, Pittsburg, Portland, Providence, St. Louis, Toledo, Troy, and Wilmington (Del.); the Chambers of Commerce of Cincinnati, Milwaukee, New Orleans, New York, Richmond, and St. Paul; the Boston Corn Exchange, Dubuque Produce Exchange, New York Produce Exchange, Peoria Merchants' Exchange, Philadelphia Commercial Exchange, and St. Louis Union Merchants' Exchange. Its purpose, as stated in its articles of organization, was to promote the efficiency and extend the usefulness of the various Boards of Trade, Chambers of Commerce, etc., organize for general commercial purposes, to secure unity and harmony of action in commercial usage, custom, and law, and to consider all questions pertaining to finance, commerce, and the industrial interests of the country.

This national organization has met annually in different cities of the country, its meetings from 1879 to 1888 having been held at Washington. Frederick Fraley, of Philadelphia, its first president, has presided over every successive meeting, and was re-elected at the meeting held in 1888 at Washington, at which meeting 21 societies were represented. On Nov. 14, 1888, a meeting was convened at Chicago. In regard to the general scope of interests considered at the meetings of the National Board of Trade, it may perhaps best be shown by naming those debated at the 1888 meeting. These included the subjects of adulterations, coast defences, river and harbor improvements, postal telegraph, agricultural reports, revenue, trade reciprocity with Canada, bankrupt legislation, naturalization laws, national bankruptcy law, currency, questions of shipping, pilotage and quarantine, etc.

The meetings of the city associations consider questions relating principally to local interests, but the annual deliberations of so many bodies composed of the most experienced business men of our various cities, and of a national board made up of selected delegates from the local boards, cannot but be of the utmost benefit to the commercial and industrial interests of the country, and go far towards the solving of many mooted questions in social and political economy and the promotion of the welfare of mankind in general. The great growth of modern business and the diversity of interests involved has necessitated the formation in many cities of associations devoted to the promotion of particular interests, such as corn exchanges, produce exchanges, and the like, more restricted in their interests than the general boards of trade, yet working in harmony with them. Some examples have already been named, and there may be added, as secondary to the old-established New York Chamber of Commerce, the New York Importers' and Brokers' Board of Trade (1872), and the New York Board of Trade (1874). (C. M.)

TREASON. The crime of treason has in the United States undergone changes in its constitution from its character as prevailing in England that are characteristic of the difference between governments that have a purely popular basis and those that rest wholly or partly upon the derivation of public authority by heredity. The government of Great Britain is popular only as it regards one of the branches of its legislature, while the Crown and Lords, constituting the other two branches, still claim their public functions through heredity. The Crown of Great Britain still preserves attributes common to monarchies absolute and limited that give to the act of treason a personal character in its bearing upon the personal

See Vol. XXIII. See Vol. XXIII. United States undergone changes in its constitution from its character as prevailing in England that are characteristic of the difference between governments that have a purely popular basis and those that rest wholly or partly upon the derivation of public authority by heredity. The government of Great Britain is popular only as it regards one of the branches of its legislature, while the Crown and Lords, constituting the other two branches, still claim their public functions through heredity. The Crown of Great Britain still preserves attributes common to monarchies absolute and limited that give to the act of treason a personal character in its bearing upon the personal

sovereign. Hence in England to compass the death of the occupant of the throne, as the lawyers express it, is an act of treason. In the United States the sovereignty resides in the public as a community, and an act of treason is necessarily one against the entire community. To this idea the Constitution of the United States is conformed, since it declares that treason against the United States shall consist only in levying war against them, or in adhering to their enemies, giving them aid and comfort. It is possible for a single person to do all that need be done to take the life of the personal sovereign, but to antagonize the government of a community implies means of a very different nature.

The definition given to treason, as used in the Constitution, and accepted as authoritative, is that it implies the assembling of a body of men for the purpose of overturning or resisting the government by force, and the performance of some act looking to that end, although such act need not amount to a collision of arms. This definition is in harmony with the spirit of popular institutions, for it accords with the popular right to deliberate together and plan changes of the government or of its policies, general or particular, so long as force is not to be the instrument for the accomplishment of that purpose. That which the whole people have a right to accomplish can be undertaken by any limited portion of the whole number if force is not resorted to. An assembly for deliberative purposes alone is not an act of war, for though war may be the product of deliberation, it represents a distinct step beyond that of deliberation. The act of war is recognized as a corporate act in which more than one must be engaged, although the minimum number has not been agreed upon, but according to the judicial interpretation a maximum is not necessary that could be supposed sufficient to accomplish the end intended.

The assembly, in order to fall under the censure of the law, must be to act rather than to deliberate, and that action must be directed against the authority of the government, using force as its intended instrument. To resist a subordinate officer of a government is not that kind of resistance that is contemplated by the Constitution, unless an intention accompanies it to meet the whole force of the government, should it be brought into exercise. An instance of this class appears in the case of the Whiskey rebellion in Pennsylvania, where force was directed against the judicial power of the government.

According to the European system, from which our own is derived, the effect of treason upon an individual convicted of it is to deprive such person of all civil and political right in addition to deprivation of life. His capacity both of holding property and of transmitting it to others by descent is taken away. This result might not only ensue as the consequence of conviction of such crime, but might be produced by an act of legislation. The Constitution of the United States precludes this consequence and leaves the civil consequences of treason to be applied through a conviction by the judicial authority. The laws of the United States go a step farther and limit these civil consequences to the life of the person convicted as it regards the disposition of property at death.

In 1790 the crime of treason was defined by Congress in harmony with the provision of the Constitution. No other legislation on that crime appears to have taken place until the rebellion of 1861, which called forth in the following year provisions of law of a more definite character than had previously existed.

The history of the United States presents some striking instances of treasonable conduct. The treason of Gen. Arnold during the Revolutionary war was an important military fact, but gave rise to no legislative or judicial consequences. The most notable event of that class occurring in the first half of the century of our national existence was the attempted invasion of Mexico by a force raised to carry out the plans of

Aaron Burr, while the last half of that century is signalized by the attempt of several States of the Union to secede therefrom. The former was an effort to take advantage of the divergence of interests between the Atlantic States and those bordering on the Mississippi River, while the latter instance was an effort that arose from differences of interests and sentiment between States bordering on the Atlantic. Kentucky and Tennessee were the first among the group of States that depend upon the great waterway afforded by the Mississippi River, which before the days of railroads was the only avenue of commerce upon which the vast region embracing the interior of this continent could rely where not touching on the Great Lakes. The soil and jurisdiction of Kentucky were claimed by Virginia, and those of Tennessee by North Carolina. The people of these colonies claimed their independence of those States, and persisted in these claims until time and immigration established their claims. This conflict of jurisdiction sowed the seeds of discontent and alienated the interests and affections of the respective peoples. The Atlantic States were connected together by common interests of navigation in which the Western States did not participate, while the commercial advantages afforded by the Mississippi River appeared to be disconnected from those affecting the Atlantic States. While the west bank of the Mississippi was controlled by France, then under the authority of Napoleon, Mexico and Florida, held by the Spanish, lay at the outlet of that river. The purchase of Louisiana in part satisfied the demands of the people of the valley of the Mississippi, but Spain desired still to hold the advantages of the trade of that river. Taking advantage of this disturbed condition of popular feeling and interest and of the unsettled policy of the Western States, Burr devised a scheme of taking forcible possession of the Spanish territories. Many believed that his plan was to bring about disunion as an ultimate consequence of his bold enterprise, and this impression had doubtless much to do with the activity that counteracted his plans. That Burr appealed to the discontent of the people of the West and excited among them a desire to advance their local interests by a striking adventure although in disregard of their allegiance to the Union, may be assumed. Places of assembling troops and storing military supplies were established, and men and supplies collected, but the vigilance of the government prevented such secrecy and deliberate preparation as was necessary for the consummation of his plans. Burr hastily embarked with a small body of men to descend the Mississippi, hoping to increase his force as he advanced. In this he was disappointed, as the enterprise was broken up by the action of the government before he reached New Orleans, and he sought to escape but was captured and made a prisoner in Alabama. Taken to Richmond, he was there indicted, with several of his associates, for treason and misdemeanor. His trial resulted in his acquittal of both offences.

If what Burr intended had been consummated it would have been an act of war against a friendly power, but such an act would not necessarily involve treason against the United States. Assembling troops within the United States for such a purpose, although contrary to its laws, would not necessarily imply that those troops were intended to come into collision with the civil or military power of the United States. Such a collision might occur, and in fact was likely to occur, but it would only be when the expeditionary force was confronted by the authority of the United States that the intention directing it could be brought to a test. The intention that constitutes treason a crime must be evidenced by some overt act, and such act could only appear in the presence of some exercise of governmental authority adverse to the plans of the expedition. Had its direct object been to oppose force to the authority of the government a different case would have existed, but such an intention was not to be presumed

in the present case; if there was a covert design to use force against the authority of the government that fact could only be disclosed when suitable circumstances brought it to light.

If Burr's ultimate intention embraced disunion of the States as a consequence of a turn of affairs growing out of the attack upon Mexico, that expectation could not enter into the question of treason as connected with the early stages of the movement, for that would depend upon the drift of events rather than upon a concerted scheme of action. Burr's enterprise is distinguishable from others that have since that time occurred by the magnitude of the intended plan and the power of the man both personally and as derived from his having held the office of Vice-President of the United States.

The rebellion of 1861 presents marked instances of treason. It was brought about by persons owing allegiance to the United States although disclaiming that fact, and the first important act was an attack by armed bodies of men upon the military force of the United States. Whatever may have been the actual or assumed grounds of this act of war, in its legal character it was an act of treason. Elaborate legislation by Congress was called out by the resistance offered to the government. In its relation to the question of treason the stage of hostilities should be divided into two parts, the one prior to the recognition by Congress of the existence of a state of war between the opposing forces, and the other after such recognition had taken place. Congress was the only power that could declare war under the Constitution, and until such declaration was made the individuals engaged in rebellion could only be regarded as personally responsible for their conduct inimical to the government. The fact that other powers might recognize the Confederate States as entitled to the character of belligerency could not change the question as it regarded the fact of citizens of the United States making war against that power, for the action of foreign powers could not produce any change in the domestic effect of the laws of the United States.

When Congress declared the state of war to exist it did so because it found that the hostile forces were under the control of a government that had secured actual control over the people of the section engaged in rebellion. That declaration announced that the action of the United States would be against such government and not against the individuals of which it was composed. The hostile conduct of the people of that region became merged in that of the government which had obtained control of them and the arbitrament of war displaced that of civil judicature. But although the recognition of the state of war properly suspended civil functions acting in the same sphere to deal with questions of that character, yet at the conclusion of the war the responsibility for all acts of hostility committed before the declaration of war was revived, and legally the penalties for treason might have been imposed. But there is a cause that tends to modify the strictness of the law in cases of the class under consideration, and that is a humane sentiment that has obtained great force among civilized peoples that operates against the infliction of individual penalties in cases where popular commotion has eventuated in organized armed resistance to the public authority. It was this sentiment prevailing at the close of the rebellion that resisted attempts to enter upon any general policy of prosecuting for acts of treason committed during those stages of the conflict where the penalties for treason were appropriate.

It would not be a just criticism upon the leniency of the government at the close of the war to charge it with weakness in not vindicating the right of government and marking the duty of the citizen by imposing penalties for acts of treason committed, for the sentiment that induced such leniency was a cause of a nature recognized in all systems of jurisprudence as

appropriate to modify the conduct of the administration of justice.

The fact that in the short existence of this nation so many instances have occurred in which treason, actual or incipient, has been applied against this government is not an evidence that the attachment of the people to their government is less than in countries where a more rigid régime exists, but is the natural consequence of the fact that the susceptibility of our governmental forms to change arising from popular causes induces that liberty to run out into excesses in that direction. A more mature experience will lead to a more distinct discrimination between legitimate and improper means of inducing change in the structure and administration of the government.

(A. J. W.)

TREASURY. The U. S. Treasury Department was originally established by act of Congress of Sept. 2, 1789, and numerous amendments and enactments have since so augmented its business and proportions that it is now the largest and most important of all the executive departments of the United States government. It is presided over by a Secretary, who is appointed by the President and confirmed by the Senate. Upon this officer devolves the duty of digesting and preparing plans for the improvement and management of the revenue and for the support of the public credit. He is required to superintend the collection of the revenue; to prescribe forms for keeping and rendering the public accounts, and of making returns; to make reports annually, and specially when called upon, and to give information to either branch of Congress, in person or in writing as may be required, respecting matters referred to him, and as to all matters pertaining to his department; to grant, under the limitations established by law, all warrants for moneys to be drawn from the treasury in pursuance of appropriations made by Congress; and generally to perform all such duties connected with the national finances as are required by law. The functions of this officer and the multifarious business intrusted to his supervision have been greatly expanded within the past quarter of a century. These, as may be imagined from a contemplation of the vast interests and resources of the country, are numerous, and, among others, embrace the management of the public debt, the national currency and coinage, the supervision of the national banks, the control and management of matters pertaining to the internal revenue system, the customs service, the commercial marine, the light-house and buoyage system of the country, the survey of the coast and interior triangulation of the United States, the construction of public buildings under control of the department, the collection of commercial statistics, the inspection of steam-vessels, the marine hospital service, the life-saving service, and the prevention and detection of fraud upon the revenue.

Two assistant-secretaries of the treasury are also appointed by the President and confirmed by the Senate, either of whom may be designated as acting-secretary during the absence or inability of the secretary. There are also in the office of the secretary a chief clerk and nine division chiefs, upon whom, under the general supervision of the secretary and assistant-secretaries, devolves the general direction of the routine business and operations of the office. In addition to the officers connected with the secretary's office proper there are in the department a first and second comptroller, a commissioner of customs, and six auditors, who constitute what are known as the accounting officers of the treasury. These officers are also appointed by the President and confirmed by the Senate, and hold office until the appointment of their successors. All accounts for the receipt and expenditure of public moneys are subject to the examination and settlement of these officers, as the same come respectively within the provision assigned to each by the statutes. Their official duties, as may readily be imagined, are of vast

magnitude, responsibility, and importance. There is required of them, in the discharge of those duties, not the capacity of the accountant alone, but of a mind trained to and adapted for administrative and judicial investigation. Those duties embrace the examination of facts, the sifting of evidence, the determination of conflicting claims and adverse interests, as well as the construction of statutes and the application of settled and well-defined principles of law.

The auditor provided for by the act creating the department, was then known as auditor of the treasury. His duties were to receive and audit all accounts. Subsequently, by the act of March 3, 1817, four additional auditors were provided for, and he was then denominated the first auditor. He is required by law to examine all accounts relating to the receipts from customs; all accounts accruing in any department on account of salaries; all accounts for salaries and expenses of judges, marshals, and other officers of United States courts; expenses connected with the construction of public buildings; and generally all accounts relating to the civil expenses of the government with the exception of those incurred in the consular and diplomatic service and internal revenue bureau. Early in this century such a distribution of the public business was demanded as was calculated to result in a prompt settlement of public accounts. Hence the necessity for the act of March 3, 1817, which provided for five auditors, to whom were assigned, respectively, the settlement of the accounts of the different departments. The duties of the second auditor, as now defined, are the examination and settlement of accounts relating to the pay and clothing of the army, ordnance service, subsistence of officers, bounties to soldiers, hospital stores, and contingent expenses of the war department, and of all accounts relating to Indian affairs. The third auditor is required to examine all accounts relative to the subsistence and transportation of the army, and generally all accounts of the war department other than those assigned by law to the second auditor, and all accounts relating to army pensions. The fourth auditor receives and settles all accounts relating to navy pensions, and accounts pertaining to the naval service. The fifth auditor receives and examines accounts accruing in or relative to the diplomatic and consular service; accounts relating to the census, the National Museum, and the contingent expenses of the patent office. The office of the sixth auditor was originally created by the act of July 2, 1836. Previously the duties had devolved on the fifth auditor in addition to his other duties. The duties of the sixth auditor bear relation both to the Treasury and Post-Office departments. He is an officer of the treasury, and under the direct control of the secretary, but, at the same time, he is also by law subject in certain respects to instructions which may be given by the Postmaster-General. He is required by law to examine all accounts relating to the postal service, and to report to the Postmaster-General all balances found on settlement of such accounts. Unlike the other auditors, his settlements of accounts are not subject to revision by any other officer, except when dissatisfaction is expressed by any person or by the Postmaster-General, in which case an appeal may be taken within twelve months to the first comptroller, whose decision is final. All the accounts passed upon by the other five auditors go to the first or second comptroller or commissioner of customs for re-examination. All returns relative to the survey and sale of public lands are made to the commissioner of the General Land Office in the Interior department, who is required by law to audit and settle all public accounts relative thereto, and to certify the balances and transmit the accounts to the first comptroller of the treasury for his examination and decision. He is thus made an auditing officer, with duties relating to accounts pertaining to public lands or of like character as those devolving on the auditors of the treasury, with regard to their several subjects of accounting.

The first comptroller is required to examine all accounts settled by the first auditor except those relating to receipts from customs; all accounts settled by the fifth auditor and by the commissioner of the general land office, and to certify to balances arising thereon to the register of the treasury. He is also required to countersign all warrants drawn by the Secretary of the Treasury which are authorized by law, and to superintend the recovery of all debts certified by him to be due the United States, and for that purpose to direct such legal proceedings as may be adapted to enforce prompt payment thereof. The second comptroller examines all accounts settled by the second, third, and fourth auditors, and certifies the balances arising thereon to the heads of the departments in which the expenditures have been incurred. He also countersigns all requisitions drawn on the Secretary of the Treasury by the Secretaries of War and of the Navy.

The office of commissioner of customs was created by the act of March 3, 1849. At this time there were two revising officers, already described as first and second comptrollers, the former of which was charged with the duties transferred by that act to and now performed by the commissioner of customs. He is required by law to examine all accounts settled by the first auditor relating to the receipts from customs, and to certify to balances arising thereon to the register of the treasury. In addition to the foregoing there are also embraced in the organization of the department the following-named officers: Treasurer of the United States; Register of the Treasury; Commissioner of Internal Revenue; Comptroller of the Currency; Director of the mint; Chief of the Bureau of Engraving and Printing; Supervising Inspector-General of the Marine Hospital establishment; Supervising Inspector-General of Steamboats; General Superintendent of the Life-Saving Service; Superintendent of the Coast and Geodetic Survey; Chief of the Bureau of Commercial Statistics; Supervising Architect; Commissioner of Navigation; Chief of the Secret Service; and the Light-House Board.

Persons appointed to the office of Secretary of the Treasury, first comptroller, first auditor, treasurer, or register, are prohibited by law from being concerned or interested in trade or commerce, public lands or other public property, or public securities of a State, or of the United States, and from taking to his own use any emolument or gain for negotiating or transacting any business in the treasury department other than is allowed by law. The duties of the register are to keep all accounts of the receipts and expenditures of the public money, and of all debts due to or from the government; to receive from the first comptroller and commissioner of customs all accounts finally adjusted by them, and to transmit to the Secretary of the Treasury copies of the balances of accounts so certified; to record all warrants for the receipt of payment of moneys at the treasury, except those drawn by the Postmaster-General and those by the Secretary of the Treasury upon requisition of the Secretaries of War and of the Navy. This officer also has charge of the accounts of the issue and redemption of bonds, notes, and other securities of the United States, and is custodian of the records and files pertaining to the accounts arising in the civil branches of the government. The office of Treasurer of the United States was created by the act establishing the Treasury department. The treasurer is required to give bond in the penalty of \$150,000, conditioned for the faithful discharge of his office, and for the fidelity of the persons to be employed under him. He receives and keeps the moneys of the United States, and disburses them only upon warrants drawn by the Secretary of the Treasury. He is also charged with the custody of all public moneys deposited in the various sub-treasuries and depositories throughout the country; he receives from the Bureau of engraving and printing, and counts and seals preparatory to use, United States

legal tender notes for the reserve fund kept on hand to replace worn and mutilated notes of the same character which are from time to time redeemed and retired from circulation; he acts as agent for the redemption of national bank notes; has entire charge of the payment of interest on the public debt; is custodian of bonds held in trust for various tribes of Indians, and of bonds purchased from time to time by the Secretary of the Treasury, as trustee of the sinking-fund established by law for the liquidation of the debts due the government from the Union Pacific and Central Pacific Railway Companies, and is charged generally with the safe-keeping of all public funds. The commissioner of internal revenue, under the direction of the Secretary of the Treasury, is invested with the general superintendence of the assessment and collection of internal revenue taxes, embracing the preparation and distribution of all instructions, regulations, forms, blanks, stamps, and other matters pertaining thereto.

The office of comptroller of the currency was created by the national banking act of 1864. The comptroller is charged, under the general direction of the Secretary of the Treasury, with the execution of all laws relating to the issue of a national currency secured by U. S. bonds. He is appointed by the President on the recommendation of the Secretary of the Treasury, by and with the consent of the Senate, and holds office for a term of five years, unless sooner removed by the President. He is assisted by a deputy, who has the power and performs the functions and duties of the comptroller in case of a vacancy in the office or during the absence of the comptroller. Both officers give bond for the faithful discharge of their duties, and are prohibited by law from being interested in any association issuing national currency. The comptroller is required to make an annual report to Congress upon the condition, resources, and liabilities of national banks, and upon all matters relating to banking institutions generally. The Director of the Mint is the head of a bureau of the treasury having charge of all U. S. mints and assay offices. He receives his appointment from the President and holds office for a term of five years, unless sooner removed. He is required to make an annual report at the close of each fiscal year, and from time to time such additional reports, setting forth the operations and condition of these institutions, as the Secretary of the Treasury may require. The Bureau of Engraving and Printing grew out of the necessity for the issue of paper currency to meet the demands on the government in the early part of the war of the rebellion, and has since attained such excellence that its work rivals in artistic merit all former productions of like character. The chief of the bureau is charged with the duty of the engraving and printing of all U. S. bonds, legal tender notes, national bank notes, gold, silver, and currency certificates, certificates of deposit, interest checks, disbursing officers' checks, and internal revenue stamps.

The supervising surgeon-general of the marine hospital service (see MARINE HOSPITAL) is charged with the supervision of all matters connected with the marine hospital service, and with the disbursement of the fund for the relief of sick and disabled seamen employed on the vessels of the mercantile marine of the oceans, lakes, and rivers, and of the revenue cutter service, the general superintendence of the marine hospitals, the purveying of supplies, the orders, details, and assignment of medical officers, and the examination of property returns. The supervising inspector-general of steamboats administers the laws relating to the inspection of vessels, and is aided in the work by a board of supervising inspectors and a corps of local inspectors established at the different ports of the country. Inspection is made of hulls and boilers of all vessels engaged in the transportation of goods and passengers.

The LIFE-SAVING SERVICE (q. v.) is under the

charge of a general superintendent. His duties embrace the establishment of life-saving and life-boat stations and houses of refuge at proper points along the coast, for affording aid to shipwrecked vessels thereon, and measures generally calculated to promote the humane purposes of the law; also the selection of sites for the stations and houses of refuge; the preparation of plans and specifications for buildings; the making of contracts for their construction; the testing, erection, and purchase of their apparatus, equipment, and supplies; the organization of the service, and the preparation of regulations for the government of its officers and employes; the employment of crews of experienced surfmen, and the regulation of their wages and duties; the supervision of all expenditures and accounts connected with the service, and the preparation of estimates for its support. They also embrace the award of medals for the saving of life from the perils of the sea; the collection of statistics of marine disasters; the investigation of circumstances attending shipwrecks, and the preparation of the annual report of the operations of the service.

The office of the COAST AND GEODETIC SURVEY (q. v.), like the Light-House Board, because of its close connection in its labors and purposes with the interests of commerce and navigation, has become by process of time attached to this department. The service was originally provided for by the act of Feb. 10, 1807, authorizing the President to cause a survey to be made of the coasts of the United States. The act of March 3, 1843, provided for the organization of a board to adopt a plan of reorganizing the mode of executing the survey, and authorized the employment of as many of the officers of the army and navy as might be found compatible with the successful prosecution of the work, the officers of the navy to be employed on the hydrographical parts and those of the army on the topographical parts of the work. The results of the surveys of the coasts, and of the labors and observations incident thereto, are exhibited in maps and charts prepared and engraved by skilful draughtsmen and engravers employed for this special purpose and in the annual reports to Congress. The general operations of the bureau are at present directed by a superintendent appointed from civil life.

The duties of the chief of the Bureau of Statistics are to collect, arrange, and classify statistical information showing the condition of the agriculture, manufactures, and domestic trade of the several States and Territories. He is required to report annually on the statistics of commerce and navigation of the United States with foreign countries, and publish annually, quarterly, monthly, and occasional reports embodying information relating to imports and exports, immigration, shipping, and other matters relating to the foreign and domestic trade of the country. The supervising architect of the treasury prepares plans and designs for custom-houses, court-houses, post-offices, sub-treasuries, mints, appraisers' stores, warehouses, and all other public buildings under the control of the department, and supervises their construction and repair. The Bureau of Navigation was created by the act of July 5, 1884, and placed under the immediate control of a commissioner of navigation, who is charged with the general superintendence of the commercial marine and merchant seamen of the United States, so far as vessels and seamen are not subject to the supervision of any other officer of the government. He is required to decide all questions relating to the issue of registers, enrolments, and licenses of vessels, and to the filing and preservation of those documents. He is charged with the supervision of the laws relating to the admeasurement of vessels, and the assignment of signal letters thereto, and of determining all questions growing out of the execution of the laws relating to the service and those relating to the collection of tonnage tax. He is also required to prepare and publish annually a list of the steam and

sailing vessels of the United States belonging to the commercial marine, specifying their names, rig, tonnage, home port, and place and date of building, and to investigate the operations of the navigation laws and report to the Secretary of the Treasury any needed amendments thereto.

The chief of division of special agents is charged with the supervision and enforcement of the regulations for the prevention of smuggling and frauds on the customs revenue; the supervision over customs districts and over the acts of customs officers and their books and records, with a view of securing uniformity in their methods of transacting business; the supervision of the transportation of merchandise in bond, and the investigation of cases arising from alleged irregularities in connection with such transportation, and the enforcement of the laws and regulations relating to the establishment of bonded routes and mode of transportation. The principal duties of the chief of the secret service division of the department are to detect and to bring to trial persons engaged in counterfeiting the coin, currency, and securities of the United States, and those engaged in passing or dealing in the same, as well as to detect other felonies committed against the laws of the United States relating to the pay and bounty laws.

The Light-House Board is composed of two officers of the navy of high rank, two officers of the corps of engineers of the army, and two civilians of high scientific attainments, together with an officer of the navy and an officer of engineers of the army as secretaries, all of whom are appointed by the President. Under the superintendence of the Secretary of the Treasury the board is required to discharge all administrative duties relating to the construction, illumination, inspection, and superintendence of light-houses, light-vessels, beacons, buoys, and their appendages, embracing the security of foundations of works already existing, the purchasing of illuminating and other apparatus, supplies, and materials of all kinds for building and for rebuilding, and the keeping in good repair the light-houses, light-vessels, beacons, and buoys of the United States. It is required also to take charge and custody of all the archives, books, documents, drawings, models, and other property appertaining to the light-house establishment. (See LIGHT-HOUSE.)

* The office of solicitor of the treasury was established by act of May 29, 1830. Previously there had been an agent of the treasury whose duty comprised the collection of official balances due by delinquent officers of the government and of other debts due the United States. In addition to the duties which devolved upon this agent the solicitor is required to take cognizance of all frauds or attempted frauds upon the revenue, and to exercise a general supervision over the measures for their prevention and detection, and for the prosecution of persons charged with the commission thereof. It is his duty also to establish such regulations for the observance of collectors of customs and of officers of U. S. courts respecting suits in which the United States is a party, as may be necessary for the just responsibility of those officers and the prompt collection of all revenues and debts due and accruing to the government, excepting those arising under the internal revenue laws, which are in charge of the solicitor of internal revenue. Though nominally attached to the treasury department, he is in reality an officer of the Department of Justice, and may be required by the Attorney-General to give his opinion in writing on any question of law submitted by any department for the opinion of the latter, except questions involving a construction of the Constitution of the United States, and to perform any other duty required of the Department of Justice or any officer thereof.

It will thus be seen that the details involved in the transaction of the immense and varied business of the fiscal department of the United States government are

wisely and systematically distributed among a series of responsible officers. The clerical and other forces employed in the various offices and bureaus number 15,697, of whom 2852 are in bureaus at Washington, 4450 in the customs service, 3303 in the internal revenue service, 948 in the mints and assay offices, 225 in the several sub-treasuries, and 3919 in the life-saving, marine hospital, steamboat inspection, and revenue marine bureaus, and in the various public buildings and other branches of the department located throughout the country.

The general system of accounting in force in the department—which was conceived and put in operation by Alexander Hamilton, its first secretary—has proven so admirably adapted to the purposes for which it was intended that but few modifications have since been made in its practical application.

The following statements exhibit the principal operations of the department during the fiscal year ending June 30, 1888, and the condition of the treasury at the close of the year:

Receipts and Expenditures.—The revenues of the government are mainly derived from duties on imports, and internal taxes upon distilled spirits, fermented liquors, tobacco, and banking. The expenditures are mainly on account of the war and navy departments, pensions, interest on the public debt, and the civil service. The revenues from all sources for the fiscal year 1888 aggregated \$379,266,074.76, of which \$219,091,173.63 were from duties on imports, \$21,296,871.98 from internal taxes, \$11,202,017.23 from sales of public lands, and \$24,676,011.92 from miscellaneous sources. The expenditures for the same period were \$267,924,801.13, as follows: civil and miscellaneous, \$72,952,260.80; war department, \$38,522,436.11; navy department, \$16,926,437.65; Indian service, \$6,249,307.87; pensions, \$80,288,508.77; premium on bonds purchased, \$8,270,842.46; and interest on the debt, \$44,715,007.47, leaving a surplus of \$111,341,273.63, of which \$43,732,550.00 was applied to the redemption of bonds for the sinking-fund, and \$31,081,013.05 to ordinary redemption of the debt. As compared with the previous fiscal year, there was an increase in the revenues of \$11,041,749.38 in the following items: duties on imports, \$1,804,280.50; internal taxes, \$5,473,480.76; sales of public lands, \$1,947,730.81; and from miscellaneous sources, \$1,816,257.31. There was a decrease of \$3,178,952.28 in the following: tax on circulation of national banks, \$637,284.33; sales of Indian lands, \$598,941.38; repayment of interest and sinking-fund, Pacific railroads, \$427,200.62, and from sales of old public buildings and miscellaneous sources, \$1,515,525.95, making a net increase of revenue of \$7,862,797.10. The expenditures were practically the same in the aggregate as for the fiscal year 1887.

The National Banks.—The following shows the condition of the national banks on June 30, 1888, as represented by reports from 3120 banks then in operation.

<i>Resources.</i>	
Loans and discounts.....	\$1,619,999,200.68
Overdrafts.....	8,125,364.15
U. S. bonds to secure circulation.....	177,543,900.00
U. S. bonds to secure deposits.....	55,788,000.00
U. S. bonds on hand.....	7,830,150.00
Other stocks, bonds, and mortgages.....	96,265,812.31
Due from approved reserve agents.....	158,133,598.31
Due from other national banks.....	101,689,774.90
Due from State banks and bankers.....	22,714,258.27
Real estate, furniture, and fixtures.....	61,101,833.19
Current expenses and taxes paid.....	5,685,313.21
Premiums paid.....	18,903,434.54
Checks and other cash items.....	16,855,801.15

The Coinage.—The coinage executed at the mints of the United States during the fiscal year 1888 was :

Denomination.	Pieces.	Value.
<i>Gold :</i>		
Double-eagles.....	815,087	\$16,301,740.00
Eagles.....	899,828	8,998,260.00
Half-eagles.....	599,102	2,995,510.00
Three dollars.....	11,366	34,098.00
Quarter-eagles.....	6,273	15,682.50
Dollars.....	18,880	18,880.00
	2,350,534	28,364,170.50
<i>Silver :</i>		
Standard dollars.....	32,718,673	\$32,718,673.00
Half-dollars.....	5,673	2,836.50
Quarter-dollars.....	778,673	194,668.25
Dimes.....	12,199,175	1,219,917.50
	45,702,194	34,136,095.25
<i>Minor Coin :</i>		
Five cents.....	15,207,173	\$ 760,358.65
Three cents.....	45,573	1,367.19
One cent.....	45,725,073	457,250.73
	60,977,819	1,218,976.57
Total coinage.....	\$109,030,547	\$63,719,242.32

Imports and Exports.—The value of the merchandise imported into the United States during the fiscal year 1888 was \$723,879,813 as against \$692,319,768 during the previous fiscal year. The value of the exports of the products of agriculture, manufactures, mining, forestry, and the fisheries is thus shown :

Products of	Value.	Per cent.
Agriculture.....	\$500,785,314	72.24
Manufactures.....	130,312,408	19.08
Mining.....	18,067,051	2.45
Forestry.....	23,991,092	3.50
Fisheries.....	5,539,780	1.00
Miscellaneous.....	5,166,591	.75
Total.....	\$683,662,236	100.00

The value of the exports of agricultural products fell off from \$523,077,223 in 1887, to \$500,785,314 in 1888, while the exports of all other commodities increased from \$179,945,700 to \$183,076,922.

The Public Debt.—The following table shows the total amount of the national debt on June 30, 1888 :

Character of debt.	Amount.
Bonds at 4 per cent.....	\$222,207,050.00
Bonds at 4 per cent.....	714,177,400.00

Character of debt.	Amount.
Refunding certificates at 4 per cent.....	\$ 138,050.00
Navy pension fund at 3 per cent.....	14,000,000.00
Interest accrued on the above.....	9,671,459.96
Debt on which interest has ceased.....	2,496,095.26
Interest on matured debt.....	168,267.86
Bonds issued to Pacific Railroads.....	64,623,512.00
Interest accrued thereon.....	1,952,745.32
Demand and U. S. notes.....	346,737,823.50
Certificates of deposit.....	14,415,000.00
Gold certificates.....	119,887,370.00
Silver certificates.....	200,387,376.00
Fractional currency.....	6,922,643.82
Total.....	\$1,717,784,793.72

The net debt, after deducting the cash in the treasury, was \$1,165,584,656.64, as compared with \$1,279,428,737.02 at the close of the previous fiscal year.

The State of the Treasury.—The following is a statement of the condition of the public treasury on June 30, 1888 :

Liabilities.	Amount.
Gold certificates outstanding.....	\$119,887,370.00
Silver certificates outstanding.....	200,387,376.00
Currency certificates outstanding.....	14,415,000.00
Reserve for redemption of U. S. notes.....	100,000,000.00
Funds for retirement of bank circulation.....	91,952,843.65
Funds for redemption of national bank notes.....	6,976,727.62
Disbursing officers' balances.....	23,108,989.47
Transfer checks and drafts.....	3,007,955.85
Post-office department account.....	6,022,846.10
Matured debt and interest.....	14,289,926.37
Miscellaneous items.....	4,600,208.23
Balance.....	129,384,241.48
Total.....	\$714,033,484.77

Assets.	Amount.
Gold coin.....	\$203,636,964.04
Gold bullion.....	110,116,632.85
Standard silver dollars.....	243,879,487.00
Silver bullion.....	4,142,731.54
Trade-dollar bullion.....	6,477,022.82
United States notes.....	52,398,204.07
Deposits in national banks.....	59,979,039.63
National bank notes for redemption.....	6,770,380.08
Fractional and minor coin.....	26,163,776.77
Miscellaneous items.....	469,225.97
Total.....	\$714,033,484.77

(W. F. M.)

TREATY. While the government of the United States adheres to the general doctrines as to the nature and effect of treaties prevailing among the states of Europe, it has introduced changes in the method of forming such treaties that were demanded by the nature of its political institutions. The international intercourse of the European states has been largely affected by the consideration that dynastic interests were intimately interwoven with national interests, giving to that intercourse a personal as well as national character. Having in our system eliminated this personal element it was possible that treaties should be made under the supervision of some representative body sustaining close relations to the people of the United States, and yet of such stability as to insure a high degree of uniformity and persistence in the policy of our diplomatic relations with other powers. The selection of the Senate to revise the executive action in the making of treaties, leaving the power of negotiation in the hands of the President, secured at once the advantages to be derived from executive unity with those resulting from a divided responsibility in which the representatives of the people participate.

As the Senate in the performance of this function sits as an executive body and not in its character as a branch of the legislative body, the treaty-making power as it exists with us is to be regarded as strictly

executive in its nature, and therefore of the same quality as that exercised under the governments of Europe. It follows that our engagements with foreign powers are not under the legislative control of Congress but are the products of executive action alone. It is true that as to the domestic effect of a treaty it may be entirely controlled by Congress, so that obligations imposed upon the citizens and officers of this country by treaties may be remitted by Congress, and rights secured thereby may before such treaties have passed into actual execution be denied by Congress, but where the national faith has been pledged to a foreign power by a treaty duly made and ratified by the proper executive authority Congress cannot undo the obligation thus imposed without the consent of the power with which the engagement has been made. In this respect a treaty made by the national executive stands on the same footing with one made by an absolute sovereign, and that it should have that character is essential to the maintenance of international intercourse.

The Constitution of the United States gives to the domestic operation of treaties made under its authority the quality of law, declaring that they should constitute part of the supreme law of the land, but does not place the disposition made by treaties beyond the power of Congress as it regards their domestic operation. The existence of an obligation implies the possibility that the obliged party may not conform to its requirements, in which case compensations or punitive consequences appropriately follow, and such power of conforming to or declining what is demanded under an obligation must in the nature of things reside somewhere, and under our system it resides in Congress.

If there is any instance in which Congress can control the relations of the nation with foreign powers it would be found in the instance of treaties of pacification where war has been formally declared by its authority, but the current of opinion seems to flow in the direction of allowing to the treaty-making power authority to change the status of war, although created by a legislative act, into that of peace. Where, however, the conditions of peace called for the payment of money, as in the instance of the war with Mexico, under which a large portion of the present territory of the United States was acquired, an appeal to the legislature is a practical if not a legal necessity. No case has arisen to test the ability of the treaty-making power to alienate the territory of the United States except as a mere incident of the ascertainment or perfecting of uncertain or disputed boundaries. It is a singular fact that, while the legislative power of the nation is placed under constitutional limitation to keep it in proper channels, no such care has been exhibited in the case of the diplomatic powers of the government, and the existence of limitations of that which properly falls within the nature of that power must depend on inferences from rather than direct expressions of the Constitution.

The earliest stage of our national diplomacy was occupied with the establishment of relations of amity and commercial reciprocity with the various powers of Europe. A broad and liberal policy of international relationship had been mapped out while the government was still under the Articles of Confederation that was continued under the Constitution. The political policy of the diplomacy of the country was placed in a condition in which it has remained until the present day. The geographical position of the United States rendered unnecessary the diplomatic complications that are rendered necessary in Europe by the number and proximity of the competing powers, and the avoidance of foreign alliances for political purposes was early accepted as a principle of our diplomacy. Nor have the conditions tending to allow simplicity to our relations with other powers looking to political objects materially changed. Neither the security nor the influence of the United States depend upon alliances,

but have been found to be best secured by an impartial treatment of all other powers.

The development of an impartial system of international commercial intercourse engaged the attention of the early diplomats of the country and especially interested Pres. Jefferson. It was sought to place the interests of navigation and commerce upon the security afforded by a generous scheme of reciprocity broad enough to include all the powers with which the United States desired commercial relations, conferring special favors on none and withholding from none that which impartiality would confer upon them. To accomplish this it was necessary that the practice of European diplomacy by which commercial favors were balanced against political favors should be avoided and that the interests of commerce should be entirely separated from those of a political nature. The consequence of this policy was that rights of commerce and navigation were in the United States fixed by general laws equally applicable to all nations, rather than by special treaty engagements with the several powers. For many years duties upon foreign importations of merchandise and dues to which the right of navigation was subjected were established by general laws allowing no exclusion of any power that was willing to reciprocate like advantages.

This impartial policy was to a limited degree infringed by an event that marked the second stage of the diplomatic policy of the United States. The immigration into Kentucky brought an enterprising population into contact with the problem of the free navigation of the Mississippi River, the western bank of which was within the jurisdiction of France. The purchase of the right of France to the territory west of the Mississippi and which was known as Louisiana was pressed upon Jefferson upon his accession to the Presidency. He hesitated to take a step that seemed inconsistent with the views that he entertained as to the limited powers of Congress. To acquire that territory would require that Congress should expend the public money for that purpose, and such an object was not found among the enumerated powers of Congress and could by no means be regarded as a necessity of the execution of such enumerated powers. Jefferson's hesitation was overcome by the pressure of political interests, and the purchase was consummated through a treaty made with Napoleon, then First Consul of France. By this treaty certain commercial advantages within the ceded territory were allowed to France and Spain for a limited period of time, from which other nations were to be excluded, and thus Pres. Jefferson in addition to inflicting a wound upon the doctrine of States rights contradicted to a limited extent the impartial commercial system to which he had devoted his thought and effort.

The diplomacy of the United States had now entered upon the career of territorial aggrandizement which was not likely to be ended while any portion of the continent of North America lay outside of its jurisdiction. This precedent, set in 1803, was followed in 1819 by the purchase of the Floridas from Spain, and at the conclusion of the war with Mexico by a treaty purchase that carried the jurisdiction of the United States to the Pacific Ocean. In 1867 the purchase of Alaska from Russia marked the last step taken in the direction of the diplomatic policy of the extension of the territory of the United States.

The acquisition of territory by these various treaties did not encroach upon the principle of keeping apart in international intercourse political and commercial interests, so that the acquisition of advantages in reference to one of these classes should not entail disadvantages upon the other, except in the case of the Louisiana purchase, where certain exclusive privileges were granted that were not to be common to all other powers. It is true that that exclusive advantage was given as part of the price of the territory acquired, and thus something was taken from the interests of com-

merce to enhance the political interests of the country in the extension of its territories, and that as the direct interest in commerce is individual, the public interest in it being indirect merely, it was something taken from the individual advantages incident to an unrestricted commerce, to be conferred upon the public or political interest of the nation. But notwithstanding that this incident was an encroachment upon the principle that the interests of commerce should not become the price of political advantages, the limited character of the exclusive privilege conferred can hardly entitle it to be regarded as a serious departure from the antecedent diplomatic policy.

An emphatic step of departure from that policy was taken by the treaty with the Hawaiian Islands in 1875. That treaty gave a discrimination as to customs duties on merchandise interchanged between the two countries that gave to Hawaii privileges not enjoyed by other nations with which the United States had treaties and commercial intercourse, notwithstanding many of those treaties excluded imposts that were not equally imposed upon all other countries. Although the Hawaiian treaty gave similar advantages to the United States as to certain classes of merchandise introduced into the islands, yet the history of the diplomacy and concurrent legislation shows distinctly that political rather than commercial advantages prompted the action of the United States in making that treaty, naval advantages and the desire to exclude European influence from the control of the islands forming an important part of the motive to the treaty. Whether the reactionary step taken in the instance of the Hawaiian treaty is to be the first of a series of steps to lead back to the old system of trading in the interests of commerce for political advantages, and thus to defeat the systematic organization of international commercial intercourse, cannot be determined at the present time.

Modern diplomacy has assumed important functions in the development of international law that marks an advance from the condition of early diplomatic action. The international system has been formed by a slow process from the habitudes of commercial interchange and national intercourse, in this respect having the same nature as the common or unwritten law which is the product of the judicial recognition of persistent social habit. Treaties have in the past had some influence upon this process, but treaty relations between particular states have only indirect effect upon the general habitudes of international intercourse, although particular customs in process of time often become general.

It is only of late years that the spirit of diplomacy has broadened to a policy of giving systematic development to the international law. A striking effort of this character appears in the instance of the effort that was made by the United States to secure a clear and liberal definition of the relations of belligerent and neutral states by its introduction into the treaty made with Great Britain in 1871 that had a particular relation to the settlement of the Alabama claims (*q. v.*). Such efforts on the part of the United States entitle this nation to be regarded as the patron of systematic diplomacy, and are the outgrowth of the principle of impartial international relationship, that has already been referred to as in the early diplomacy of this country applied to the interests of navigation and commerce. While diplomacy was recognized as the art of aggrandizing the condition of individual states, its functions were necessarily limited, but with the development of an international spirit it has entered a more useful and interesting sphere.

The suppression of the slave-trade is another interest of international law that has received attention from the diplomacy of the United States, and as connected with this subject effort has been addressed to a more accurate definition of the right of search at sea, a subject that once involved this country in hostilities with Great Britain. (See *SEARCH, RIGHT OF.*) The

United States fully sympathized with Great Britain in her efforts to suppress the African slave-trade, but at the same time desired to guard their maritime interests against abuses of the right of visitation and search. By the treaty, negotiated by Secretary Seward with Great Britain in 1862, the principle applied internationally to the case of piracy was extended under careful limitations to the African slave-trade.

A still more important subject as affecting the administration of justice is that of the extradition of persons charged with crime from countries to which they have fled to that country in which the crime was alleged to have been committed. Apart from treaty stipulations there was no mode by which the government or country in which crime had been committed could secure persons charged with such crimes for the purposes of justice while within the territory of another power. The United States has taken a prominent place in the effort to supply what is demanded by this important international interest. In 1843 a provision of that character was negotiated with France, and in 1846 a similar provision was concluded with Great Britain. In the treaty with the latter the crimes for which extradition could be claimed are specifically enumerated, and are murder, assault with intent to commit murder, piracy, and the utterance of forged paper. A specific enumeration of the offences for which extradition might be claimed was important principally for the purpose of excluding political crimes from the class. Crimes against governmental stability and order are intimately connected with popular efforts to reform existing institutions, and as the United States recognized the right of the people of a community to adjust its government to their needs or ideas, it was unwilling to lend its assistance to sustain oppressive governments or to prevent the people from securing good ones. The diplomacy of the United States has separated the idea of an asylum for those under political oppression from that of defeating the ends of justice by harboring criminals from other countries, and has shaped its course to subserve the ends of justice without denying an asylum to the oppressed of other nations.

The United States have contributed to modern diplomacy another important feature by efforts to improve the conditions of international judicature. As it is no part of the policy of the United States to use the right of conquest for the enlargement of its territories or the enhancement of its military or political influence, no motive exists to prevent the establishment of rational methods of determining international controversies. The treaty of 1783 with Great Britain left undefined the North-eastern part of the boundaries between the possessions of the two countries. In 1794 a commission was provided for by treaty to complete the location of that boundary-line, but this commission failed to reach a satisfactory result. In 1814 it was agreed between the two powers that the question of difference should be referred to a friendly sovereign for final settlement. The King of Netherlands was selected for that purpose, who rendered a decision that was not acceptable to the United States, and, indeed, that was not in accordance with the views of Great Britain. The leading objection to the decision of the King of Netherlands was, that instead of adjudicating the exact question submitted to him, he had propounded a compromise line as best conforming to his views of the interests of the respective countries. The United States had sought a judicial solution of the points of difference, and was dissatisfied with an arbitrary conclusion that expressed nothing beyond the personal opinion of the arbitrator. Great Britain was urged to constitute a commission that should proceed according to recognized methods of adjudication. Great Britain declined these tenders, and for many years the question remained unsettled. By the treaty of 1842 with Great Britain, known as the Ashburton treaty, the question was disposed of by diplomatic methods.

The question of the North-western boundary of the United States still remaining unsettled, it was referred by the treaty of 1871 with Great Britain to the Emperor of Germany for decision, and was afterwards decided by him and carried into effect. The treaty of 1871 also made provision for the settlement of the claims against Great Britain on account of the losses sustained through depredations committed by cruisers of the Confederate government built and fitted out in English ports. The United States desired that the claims on account of such depredations should be decided on judicial principles and Great Britain yielded to that desire. A tribunal was constituted for that purpose by the treaty and methods of procedure stipulated in conformity with recognized methods of judicial procedure. The result was a decision favorable to the United States, while the procedure is universally recognized as in a judicial spirit. (See ALABAMA CLAIMS.)

The instances referred to illustrate fully the tendency of American diplomacy to formulate methods of settling international controversies that are conformable to the principles applied in domestic acts of justice. Should a time occur when the leading nations are willing to forego the opportunities of aggrandizement afforded by war, the effort of the diplomacy of the United States so well begun will be attended with the large success to which its principles entitle it.

As the government of the United States is the sole medium of communication between the people of the various States and foreign countries, the duty devolves upon it of protection to all the people of the various States and Territories travelling, residing, or trading in foreign countries, and elaborate provisions are made in treaties with the various powers to meet the contingencies likely to occur in the course of such occupation abroad.

From the first settlement of the American continent the relations of the European settlers to the Indian tribes occupying the country were adjusted by treaties, and at the formation of the Constitution this intercourse with the Indian tribes was committed to the treaty-making power of the government. Since 1873 this method of dealing with the Indians has been discontinued, and acts of Congress have taken the place of treaties as means of adjusting such relations. The history of the exercise of the treaty-making power in its application to the Indian tribes does not exhibit the same tendency to give expression to the higher principles that should actuate societies of men that appears in the other branch relating to international intercourse. As the least favorable aspect of the policy of a country is that which concerns the means for enlarging its territories, the fact just stated may be accounted for. By this important power a continent has been purchased, and an annual disbursement to supply the simple wants of a remnant of that people represents its price. (See INDIANS.) (A. J. W.)

TREITSCHKE, HEINRICH GOTTHARD VON, German historian, was born at Dresden, Sept. 15, 1834. He studied at the Universities of Dresden and Leipsic, and at the School of Agriculture at Lutzschena. In 1863 he was made professor in the University of Freiburg, but on the outbreak of the war between Prussia and Austria in 1866 removed to Berlin, where he was made editor of the government annuals, in which he had assisted since 1858. He was soon afterwards called to Heidelberg University, and thence to Berlin in 1874. He had been already elected to the German Parliament, in which he belonged to the National Liberal party. Both in speeches and in writing he gave effective aid to Bismarck's movements for German unity and a centralized government. In early years he published two volumes of *Patriotic Poems* (1856), but he afterwards confined his literary labor to historical and political affairs. In his *Historische und Politische Aufsätze* (3 vols.), he discusses historically federal government, royalty, liberty, and kindred subjects. In

his *Der Socialismus und Seine Gönner* (1875) he attacks the professorial socialism then spreading in Germany. His *Zehn Jahre Deutscher Kämpfe* (1875) treats of the movements through which the kingdom of Prussia became the German empire. This work was but preliminary to his more important and comprehensive *Deutsche Geschichte im 19 Jahrhundert* (5 vols., 1879-86). Von Treitschke exhibits the industry and sagacity of Ranke, but he has confined his labors to a much narrower field, his own country and century.

TRENTON, the capital of New Jersey, county-seat of Mercer co., is on the Delaware River, at the head of tidewater and steamboat navigation. By the New York division of the Pennsylvania Railroad it is 56 miles from New York and 33 from Philadelphia. The Bound Brook branch of the Philadelphia and Reading Railroad also connects it with those cities, and several other railroads pass through or terminate in the city. There is also daily steamboat communication with Philadelphia. Two fine bridges here cross the Delaware. Assanpink Creek divides the city into two parts. Trenton stands chiefly on high ground, and has wide, shady, well-drained streets. Handsome residences occupy picturesque sites in the suburbs. The public buildings comprise a fine State-house, U. S. government buildings, county court-house, city-hall, State Lunatic Asylum, State Arsenal, penitentiary, State Reform School, and State Normal School. There are also a high-school and several public and private schools, a public library and other libraries, an opera-house and several halls, 2 national banks, 2 State banks, and a savings bank, several hospitals and other buildings for benevolent and charitable institutions. Four daily and 6 weekly newspapers are published here. Trenton is largely engaged in manufactures, and its potteries have a deservedly high reputation. There are also extensive rolling-mills, zinc- and iron-works, and works producing saws, tools, chains, India-rubber goods, fire-bricks, and terra-cotta. The water-power of the Delaware is largely utilized for manufacturing purposes. The city has a good fire department, ample supply of water, and has gas- and electric-lights. Its population in 1880 was 29,910.

TRENTON, BATTLE OF. When Gen. Washington, in the autumn of 1776, was compelled to retreat from the vicinity of New York city, the affairs of the American patriots had sunk to a low ebb. He sought refuge in Pennsylvania, guarded by the Delaware River. The British troops, which had been slow in pursuing him, were expecting soon to cross that river and capture Philadelphia. The term of most of the American soldiers was to expire with the year. Under these circumstances Washington decided to strike a counter-blow at the British in their winter quarters in New Jersey. His full plan included a crossing of the Delaware above and below Trenton, at Bristol, and at Philadelphia. The time selected was the night after Christmas, when the enemy would probably be demoralized. The only effective crossing was made at McConkey's Ferry, 9 miles above Trenton, where Washington commanded the left wing in person. The fierce north-east snow-storm hindered even his movements and prevented the others. After he had crossed, his men, numbering 2400 all told, were divided into two divisions, Sullivan taking the river road, while Washington, with Greene, reached Trenton by the Pennington road. At Trenton Hessian mercenaries, numbering about 1550 men, under Col. Rahl, occupied barracks. The two American divisions came upon them about 8 A. M., and placed artillery in position to command the streets and roads, and detachments sent out to cut off the retreat to Princeton and to Bordentown. The Hessians' guns were quickly captured, and, though Col. Rahl exerted himself to form his troops in position, they were unable to do so. He was killed while urging an assault, and his followers surrendered. Their loss was 40 killed and wounded.

and nearly 1000 captured. Six bronze guns, over 1000 stands of arms, and various stores were taken. The American loss was 2 killed and 3 wounded, and 2 were frozen to death in recrossing the river. Washington with his army returned to his head-quarters on the same night. The Hessians were sent to Philadelphia, and marched through its streets, that the dread of them might be dispelled.

TRINITY COLLEGE. The General Assembly of the State of Connecticut in May, 1823, granted a charter for the establishment of a second college in the State, under the name of Washington College; and in 1845, in compliance with the wishes of the alumni and the corporation, the name of the institution was changed to Trinity College. The plan of the college originated with the Episcopalians of Connecticut, who had established, in 1795, a seminary of liberal learning, but who had in vain sought to gain for it the power of conferring degrees. At length, in 1818, a remarkable combination of circumstances—social, religious, and political—led to a revolution in the State, the immediate results of which were the overthrow of the "Standing Order" of Congregationalism, and the adoption of a State constitution. In the following year the long-existing vacancy in the bishopric of Connecticut was filled by the election of the Rev. Dr. Thomas Church Brownell, who had been for ten years tutor and professor in Union College, a man of learning, prudence, and practical wisdom. Under his guidance advantage was taken of the opportunity to present a petition for a new college; and after a struggle, in the literature of which one finds political and financial questions curiously mingled with those relating to religion and education, the act of incorporation was granted. The incorporators included prominent representatives of the religious bodies who had united in opposition to the old establishment; and the charter contained a clause providing that no religious test should ever be required of officers or students.

In consequence of the generous gifts of the citizens of Hartford the trustees voted to locate the college in that city, and a beautiful site was secured for the buildings. These were of brownstone, in the Ionic order of architecture, of which two were erected at once, and a third in 1845. A faculty of learned men was gathered, and the institution began its work in 1824. Bishop Brownell was chosen president; after faithful service, he retired in 1831, and was succeeded by the Rev. Dr. N. S. Wheaton, a steadfast and liberal friend of the college, who did much to enlarge its usefulness. His successors were: in 1837, the Rev. Dr. Silas Totten, professor of mathematics; in 1848, the Rev. Dr. John Williams, who left academic duties here to discharge with no less remarkable ability those of the assistant bishopric, and afterwards the bishopric, of Connecticut; in 1854, the Rev. Dr. D. R. Goodwin, a profound metaphysician; in 1860, Dr. Samuel Eliot, a man of wide and graceful scholarship; in 1864, the Rev. Dr. J. B. Kerfoot, an experienced educator, who was soon called to the bishopric of Pittsburg; and in 1867, the Rev. Dr. Abner Jackson, formerly professor here, and then president of Hobart College, who died in April, 1874. In the course of fifty years the college had experienced many changes, though it had always held firmly to its ideal as a place of liberal education under the guidance of Christian principles. Its endowments had been increased by numerous gifts, and the course of instruction, which had from the first been practically the same as that of the other colleges of New England, with provisions for special students, had been modified from time to time to meet the demands made upon it. A graduate department had been organized for the study of theology, but it had soon (in 1854) become a separate institution, and, under the name of the Berkeley Divinity School, had been located at Middletown. In 1871 the number of undergraduates for the first time reached a hundred.

Near the end of Dr. Jackson's presidency the trus-

tees accepted an offer from the city of Hartford to purchase the campus as a site for the State capitol, and elaborate plans were prepared for buildings to be erected on a new campus of eighty acres situated on a bluff in the southern part of the city. The work was delayed by Pres. Jackson's death; but his successor, the Rev. Dr. Thomas R. Pynchon, prosecuted it with great energy. In 1878 two blocks of buildings, each 300 feet long, were finished, and the college was removed to its new home. Four years later these buildings were connected by a tower 70 feet square, thus completing the west side of the great quadrangle of the architect's plans. In 1883 the Rev. Dr. George Williamson Smith was chosen president. In the following year considerable changes were made in the course of instruction, in order to introduce elective studies into the work of the latter half of the course and to provide for four distinct schemes of study; one leading to a degree in arts and two to a degree in science. An observatory and a president's house were soon built, and the last two years have seen the erection of a gymnasium and alumni hall and of the Jarvis Hall of Science, standing outside of the space reserved for the quadrangles. The style of architecture of these quadrangles is that known as French secular Gothic, and there can be included in them great piles of buildings to provide amply for the present and prospective needs of the college. The library is furnished with 30,000 volumes, and is rapidly increasing, and the museum is well supplied with material for study.

The number of alumni has been about 900, many of whom have attained eminence in various professions and walks of life. Among the liberal benefactors of past years special mention should be made of Mr. Chester Adams, of Hartford, Col. and Mrs. C. H. Northam, of Hartford (whose name has been given to the central tower), Mr. Junius S. Morgan, of London, Mr. George A. Jarvis, of Brooklyn (the donor of the hall of science), and Mr. S. M. Buckingham, of Poughkeepsie. Of those who have served in the faculty two are specially worthy of honor on account of their long connection with the college: Prof. Duncan L. Stewart (1833-1880), and Prof. John Brocklesby (since 1842). (S. H.)

TRIST, NICHOLAS PENDLETON (1800-1874), politician, was born in Virginia, and educated at West Point, where he for a time taught French. He removed to Washington, and was a warm political friend of Pres. Jackson. He had married a granddaughter of Pres. Jefferson and carefully preserved the traditions and principles of that statesman. In 1845 he was made chief-clerk of the State Department, and during the Mexican war he was sent to Mexico as the direct representative of Pres. Polk, and endeavored to control Gen. Scott's movements, so far as they had political bearing. Trist negotiated the treaty of Guadalupe-Hidalgo in January, 1848. He was afterwards U. S. consul at Havana, and finally postmaster of Alexandria, Va. He died there Feb. 11, 1874.

TRISTRAM, HENRY BAKER, English clergyman and naturalist, was born at Eglingham, England, May 11, 1822. He was educated at Durham and at Lincoln College, Oxford, graduating in 1844. After travelling for a year on the continent he was ordained and became curate of Morchard Bishop. In 1847 he went to Bermuda as chaplain and secretary to Sir Charles Elliott. After visiting the United States in 1851 he returned to England and became rector of Castle Eden, where he established a training-school for female teachers. In 1855 he was compelled by ill health to seek a warmer climate and went to Algiers. His winter excursions to unexplored localities furnished material for his first book, *The Great Sahara* (1856). In 1860 he was made vicar of Greatham and master of Greatham Hospital, which he enlarged and improved. In 1870 he was made honorary canon of Durham, in 1874 canon, and in 1880 dean. He has held also other ecclesiastical positions, and in 1879 was

offered the bishopric of Jerusalem, but declined it. He has made five expeditions to Palestine and Syria and his explorations have been recorded in several books, which have attained wide circulation. Among them are *The Land of Israel* (1865); *Natural History of the Bible* (1867); *Daughters of Syria* (1869); *Bible Places* (1872); *The Land of Moab* (1873); *Fauna and Flora of Palestine* (1884).

TROLLOPE, THOMAS ADOLPHUS, novelist, historical and descriptive writer, was born in London, England, April 29, 1810. He is a son of Mrs. Frances Trollope, whose strictures on American manners are not yet forgotten, and brother of Anthony Trollope, for whom see the *ENCYCLOPEDIA BRITANNICA*. After completing his education at Oxford University, in 1840, he produced two volumes on Brittany, followed next year by two on Western France. He then took up his residence in Florence, and has been a most prolific writer on Italy and Italian subjects. His *Impressions of a Wanderer in Italy* appeared in 1850, followed next year by *Girlhood of Catherine de Medici*, *A Decade of Italian Women*, and *Tuscany* in 1849. In 1860 he published his *Filippo Strozzi* and *Paul the Pope and Paul the Friar*. While he did not equal his brother in rapidity of production nor in popularity, yet each succeeding year, down till 1870, saw one or more new works from his pen. His novels range freely from Italian to English subjects. Among them are *La Beata*, *Marietta*, *Giulio Malatesta*, *Beppo the Conscript*, *Lindisfarne Chase*, *Gemma*, *Artingall Castle*, *Dream Numbers*, *Lemora Carolini*, *The Garstangs of Garstang Grange*, *Durton Abbey*. His most important historical work is the *History of the Commonwealth of Florence, from the Earliest Independence of the Commune to the Fall of the Republic in 1531* (4 vols., 1865). He wrote also a *Life of Pope Pius IX.* (2 vols., 1877), and in 1888 published a volume of reminiscences under the title *What I Remember*.

TROOST, GERARD (1776–1850), scientist, was born at Bois le Duc, Holland, March 15, 1776. He graduated in medicine at the University of Leyden, and practised at Amsterdam and the Hague. He entered the army of Holland as a private, but soon was commissioned in the medical department. Louis Bonaparte, while king of Holland, showed Troost special favor, and in 1809 sent him to Java on a scientific exploring expedition. He was, however, captured on the voyage and carried to France, and thence was permitted to sail for America. King Louis having abdicated, Troost settled in Philadelphia and established a manufactory of alum in Maryland. He was first president of the Philadelphia Academy of Natural Sciences 1812–17, and first professor of chemistry in the college of pharmacy 1821–22. In 1821 he joined Owen's socialist community at New Harmony, Ind., but on its failure in 1827 went to Nashville, Tenn. Here he was soon made professor of chemistry and geology in the university and in 1831 geologist of the State of Tennessee. In 1849 this position was abolished, and on Aug. 14, 1850, Dr. Troost died at Nashville.

TROUT, the name given to the smaller, river-dwelling species of the salmon genus, and also to several larger members of the genus inhabiting the great lakes and the ocean. The number of species of North American salmon and trout was enumerated at 43 in 1873, but has been reduced to 18 in the amended list of Gill and Jordan. The old genus *Salmo* has been retained for only a portion of the species, the red-spotted trout, the lake trout, and some other species being assigned to genus *Salvelinus*. The speckled trout, *Salv. fontinalis*, the brook trout of the Eastern United States, is found between 32° 30' and 55° N. lat. in the lakes and streams of the Atlantic water-shed and near the sources of a few rivers of the Mississippi system and some southern affluents of Hudson Bay. The members of this genus are known in England as charrs, in distinction from the black-

spotted trout. In America they inhabit only clear and cold mountain streams and lakes, and seldom venture to the sea, though probably restrained from doing so only by the warmth of the lower waters of the rivers. The brook trout is one of the most beautiful of fishes, though probably the least graceful of the charrs. It has a somewhat heavy head and large mouth. The back is more or less mottled and barred with olive hues and colored with large red spots, the dorsal and caudal fins being also barred and mottled. In extreme southern range the brook trout reaches Northern Georgia, where, however, it is only a fingerling, while along the Canada border it frequently reaches a weight of 10 lbs. Ordinarily it seldom weighs over 2½ lbs. It is the favorite game-fish of American waters, being the most shy, most cunning, and mettlesome of all our fish, while in beauty and delicacy of flesh it is unsurpassed. It is found from the tiniest brooks to the largest rivers, is a bold biter, but by its wariness calls out the greatest skill of anglers in its capture. In the spring it delights in rapid-flowing waters, but in hot midsummer retires to deep and shady pools. The streams, however, are being rapidly depleted of this fine game-fish, and, in the words of an experienced angler, "This is the last generation of trout-fishers. The children will not be able to find any." Yet the hardiness of the brook trout renders it well adapted to artificial culture, and it may be preserved in this manner. It has been successfully planted in Europe.

Of other American charrs may be named *S. oquassa*, an exquisite little fish of the Rangeley chain of lakes in Maine, the allied *S. arcturus*, from extreme Arctic America, and the Greenland charr, *S. stagnalis*. The great lake trout, *S. namaycush*, has been placed in the same genus, though with some peculiarities of character. It is found in all the larger lakes from New England to Alaska. It varies from 15 to 80 lbs. weight, sometimes larger, and is of high rank as a food-fish. In color it is grayish, with paler spots. Compared with the other trout it is sluggish, heavy, and ravenous, its great size and strength alone giving it value as a game-fish. It keeps low, and seldom leaps out of the water like brook trout. It is caught principally in gill-nets, and in the winter through holes in the ice. It does not ascend rivers, but spawns in the shallower places near shore. Another fish of this group, *S. malma*, the Dolly Varden trout of the Sacramento, is a beautifully colored fish, nearly related to the brook trout. It is found in all the Pacific rivers, reaching 14 lbs. extreme weight, but averaging much less. It ranks high as a food-fish, and occurs abundantly from Puget Sound northward.

The black-spotted trout, *S. purpuratus*, a widely distributed fish of the streams of the Pacific region, is classed by Jordan in the sub-genus *Salar*, as it differs in some particulars from the typical *Salmo*. It is found only in the region west of the Mississippi, extending thence to the Pacific. This species, known also as the mountain trout, spotted trout, silver trout, etc., occurs in all the rivers west of the Rocky Mountains, varying in size from 2 inches to 2 or 3 feet in length. It descends to the ocean, where it is known as salmon trout, and attains a weight of 30 lbs.

The rainbow trout of the same region, *S. irideus*, known also as brook trout, golden trout, speckled trout, etc., is a small species, from 4 to 12 inches long, its extreme weight being 5 or 6 lbs. It is found in all the mountain streams and is a good table-fish, but lacks the gaminess and activity of the eastern brook trout. It has been somewhat extensively introduced into the waters of the Eastern United States.

S. Gairdneri, the steel-head trout, is another very common western species, being found in every stream and lake from New Mexico to Washington Territory, and northward to Kamtschatka. It is more active and gamy than the rainbow trout, larger and harder, and likely to prove a more useful acquisition to eastern

waters. It averages about 15 lbs. weight. The Rio Grande trout, *S. spilargenteus*, inhabits the head-waters of the Rio Grande, Rio Colorado, and their tributaries. It is the finest food-fish of New Mexico and Western Colorado, and probably inhabits all streams of that region to the Sierra Nevada. It is larger than the rainbow trout.

Much has been done towards the artificial propagation of the more important species of trout during recent years, eggs having been taken in considerable numbers from the brook, the lake, the rainbow, and other species and the fry distributed in various streams. A large station was recently formed at Neosho, Missouri, for the propagation of trout and other fishes indigenous to that region, and several other stations are devoted to trout propagation. What the result will be is yet to be determined. (C. M.)

TROWBRIDGE, JOHN, physicist, was born in Boston in 1843. He graduated at Lawrence Scientific School in 1866, and remained there two years as teacher. In 1868 he was appointed assistant professor of physics in Massachusetts Institute of Technology. In 1870 he accepted the same position at Harvard College, where he received in 1873 the degree of Doctor of Science, and in 1879 he accepted the chair of experimental physics. At Harvard College he established the largest laboratory of its kind in America. Having observed that the time signals of the college observatory were transmitted through the earth over a great extent of territory, he suggested to Mr. Preece, of London, the possibility of telegraphing signals across large bodies of water without a wire. Mr. Preece established the fact by transmitting telegraphic signals from Southampton to the Isle of Wight. Prof. Trowbridge is associate editor of *The Journal of Science*, and his various scientific papers are to be found therein, and in the *Popular Science Monthly* and the *Atlantic Monthly*. He invented the cosine galvanometer, and is member of a number of scientific associations.

TROWBRIDGE, JOHN TOWNSEND, novelist, was born at Ogden, N. Y., Sept. 18, 1827. He was brought up on a farm, but early displayed literary proclivities. At the age of 19 he was a journalist in New York city and at 20 he went to Boston, where he wrote popular tales under the name of "Paul Creyton," and edited a weekly newspaper. His *Father Brightshopes* (1853) was the first of a long series of stories, specially adapted to boys' reading—pure, bright, and stimulating to exertion. *Neighbor Jackwood* (1855) and *The Old Battle Ground* (1859) are excellent examples. *Cudjo's Cave* (1863) and *The Drummer Boy* are tales founded on incidents of the civil war. *The South* (1866) was a record of the author's observations in his travels after the war. Trowbridge had in the meantime obtained a higher fame by his vivid and pathetic poem, "The Vagabonds," first published in the *Atlantic Monthly* in 1863, and though he has written other poems he has never excelled this sketch. After being for some years a regular contributor to the *Atlantic Monthly* he became in 1870 the editor of *Our Young Folks*, a highly successful juvenile magazine, which was afterwards merged in *St. Nicholas*. Of his later novels may be mentioned *Coupon Bonds*, *Martin Merrivale*, and *Neighbors' Wives*.

TROY, a city of New York, county-seat of Rensselaer co., is on the east bank of the Hudson River, at the head of steamboat navigation, 6 miles above Albany. It is in N. lat. 42° 44' and W. long. 73° 38'. It is on the New York Central, the Delaware and Hudson, and the Fitchburg Railroads. Street-railroads run to Lansingburg and the suburb called Albion. During the summer there is daily steamboat communication with New York. The city is chiefly on an alluvial plain, 3 miles long and over half a mile wide, but extends also over the hills to the east. Mount Ida on the south affords an extensive view of the surrounding country. River street follows the curve of

the Hudson, but other streets branching from its northern part run directly south. The court-house is an imposing marble edifice in the Doric style, and the Troy Savings Bank has a costly structure with a fine marble hall. There are 9 hotels, 9 national banks, 48 churches—some of which have fine edifices—two hospitals, orphan-asylums, a high-school, 15 public-schools, and several academies. The Rensselaer Polytechnic Institute has a national reputation. There are 2 daily and 4 weekly newspapers published here. The industrial works of Troy include cotton-, knitting-, and paper-mills, stove- and car-wheel-factories, iron- and steel-works, and bell-foundries. An important manufacture is that of shirts and collars, about 8000 girls being employed in this industry. Troy distributes its manufactured products more widely than any other city in the United States. The city has gas and electric light and water-works, for which there is an indebtedness of \$380,000, the rest of the city debt being over \$750,000. The yearly expenses exceed \$550,000. The total valuation of property is \$47,847,230. Troy was settled by the Dutch in 1659 and incorporated in 1816. Its population in 1880 was 56,747.

TRUMBULL, HENRY CLAY, Sunday-school worker and editor, was born at Stonington, Conn., June 8, 1830. He belongs to a family noted in the history of Connecticut, some of whose members are briefly sketched in the *ENCYCLOPEDIA BRITANNICA*. He was educated at Williston Seminary, East Hampton, Mass., and removed to Hartford, Conn., in 1851. Here he became State missionary for the American Sunday-School Union, and in 1861 was ordained to the ministry, that he might become chaplain of the Tenth Connecticut Volunteers. He was taken prisoner before Fort Wagner, S. C., in 1863. On returning from army service in 1865 he was appointed S. S. missionary secretary for New England, and in 1871 was made normal secretary. He removed to Philadelphia in 1875 to take charge of the *Sunday-School Times*, which he has since edited with great skill and efficiency. In 1881 he made a visit to Palestine, the chief result of which was his successful determination of the previously disputed locality of Kadesh-Barnea. Besides his interesting work *Kadesh-Barnea* (1884), he published *The Blood-Covenant* (1885), applying to the interpretation of Scripture the wide-spread usage of covenanting by shedding and mingling blood. Dr. Trumbull has also published many works on Sunday-schools, the chief being *Yale Lectures on the Sunday-school* (1888).

His brother, **JAMES HAMMOND TRUMBULL**, has become noted for his acquaintance with native American languages. He was born at Stonington, Dec. 20, 1821, and studied at Yale College, but ill health prevented his pursuing a professional career. He was corresponding secretary of the Connecticut Historical Society from 1849 to 1863, and in the meantime edited *Connecticut Colony Records* (3 vols., 1850-59). He was afterwards president of this society. His study of the American aboriginal languages commenced in 1858, and he was active in forming the American Philological Association in 1869. He was appointed State librarian in 1854; he was made assistant secretary of state in 1858; in 1861 he became secretary of state, and held that position until 1865. He has edited many documents of colonial times and has published *Origin of McFingal* (1868); *The True Blue Laus* (1876), and has contributed to various periodicals on Indian names and historical subjects.

TRUST COMPANIES. Of the various classes of financial corporations connected with the monetary system of the country, none are of more importance than trust companies; which in a degree exercise the functions of both banks and savings banks. The charters of such corporations are obtained through the State Legislature, and as a rule contain the broadest of powers. In the State of New York, during the year 1887, provision was made for their organization under a general law, which however is not applicable to com-

panies previously chartered by special acts of the Legislature. The affairs of these corporations are managed by trustees or directors elected annually by their stockholders. Most charters prohibit trustees from borrowing the moneys or securities of the corporation, and require their capital, which varies from one hundred thousand to two millions of dollars, to be invested in bonds and mortgages or designated public securities. While such charters are not uniform, the main powers conferred are common to all. They are authorized to receive money on deposit and pay interest thereon and may receive securities and other personal property from individuals or corporations, and loan money on real estate and collateral or personal securities; or act as the fiscal agent of States, municipalities, or corporations, and in such capacity receive and disburse money, and transfer, register, and countersign certificates of stock, bonds, or other evidences of indebtedness; they also act as trustees under mortgages given by corporations, and accept and execute any other municipal or corporate trusts not inconsistent with law. They accept trusts from married women, and execute trusts for them in respect to their separate property and act as agent in the management thereof; they also take and accept by grant, assignment, devise, or bequest, and hold real or personal estate on trusts created in accordance with law. They are authorized to act, under the order or appointment of courts of record, as guardian, receiver, or trustee of the estates of minors, and as depositories of moneys paid into court for the benefit of minors; and may accept and execute such legal trusts, duties, and powers in respect to the holding, management, and disposition of estates and property, real or personal, and the rents and profits thereof, or the sale thereof, as may be granted or confided to them by courts, individuals, corporations, municipalities, or other authority. And they are accountable to parties in interest for the faithful discharge of all trusts, duties, or powers confided to and accepted by them.

The services rendered by trust companies are of great value to persons associating together as corporations for the purpose of starting new industries or enterprises, where the issue of stock or bonds becomes necessary, as they are authorized to act as transfer agent of stocks, and trustee under mortgages upon real and personal property or franchises of corporations, pledged as security for bonds issued. The payment of dividends on stocks and interest on bonds are also made through them. Married women having separate estates, and maidens possessed of fortunes, who are desirous of retaining control of their property after marriage, find the services of these corporations particularly desirable, owing to the strictly confidential character of all of their business transactions. Persons wishing to provide beyond contingencies for the support, maintenance, and education of minor children, or for the support of offspring mentally incompetent, or those addicted to dissolute habits that unfit them for the management or control of property, can do so by depositing money or securities, or conveying real estate in trust to these corporations, the income from which is applied as directed. Those desiring to provide for the support of relatives or dependents, with reversion of the fund, after death of beneficiary, to designated individuals or charities, find them peculiarly adapted to the acceptance of trusteeships under such circumstances. They are also useful where deposits of money or securities are required to be made, to abide the result of litigations, the fulfilment of contracts, or the issue of transactions in the future.

Trust companies are exempted from giving bonds or other collateral security when appointed guardian, receiver, or depository of moneys paid into court; all moneys received by them in either of such characters is at the sole risk of the corporation, and for any loss thereof, their capital stock, property, and effects are absolutely liable, and in case of dissolution by the Legislature, the supreme court, or otherwise, debts due from

them as guardian, receiver, or depository of moneys paid into court usually have preference.

Several of the earlier charters (1822 and 1830) granted by the State of New York, in addition to the numerous other powers conferred, authorized the insuring against losses by fire; the insuring of lives; the granting and purchasing of annuities and the making of any other contracts contingent on the duration of life. Such extraordinary powers were exercised by but one company and for a brief period only. At present the principal business of these corporations is the receiving of deposits and the acceptance of trusts; those engaged in the receiving of deposits in the State of New York, whether domestic or foreign, are required to transfer securities to the amount of ten per cent. of their capital to the superintendent of the banking department in trust as security for their depositors and creditors. These corporations make semi-annual reports of their condition to that officer, and are subject to annual examinations by him.

Trust companies possess the general powers of corporations. On the latitude of their investments there is little restriction other than the discretion of their trustees; they loan on all classes of stocks or bonds having a home or stock exchange market value, and buy almost any good mercantile paper, not being confined to particular branches of business in the purchase of notes. With but few exceptions these corporations are located at the large money centres. Jan. 1, 1888, the capital of the trust companies of New York city alone exceeded \$14,500,000.

In the following table, compiled from both official and unofficial sources, is given the aggregate of the several items of resources and liabilities reported by the loan and trust companies throughout the United States for the years 1886 and 1887:

<i>Resources.</i>		1886-87. 58 companies.
Loans on real estate.....		\$16,269,993
Loans on personal and collateral security.....		36,544,018
Other loans and discounts.....		143,282,819
Overdrafts.....		12,810
U. S. bonds.....		28,787,717
State, county, and municipal bonds.....		178,148
R. R. bonds and stocks.....		7,400,348
Bank stocks.....		132,651
Other stocks, bonds and mortgages.....		36,428,878
Due from other banks and bankers.....		18,795,503
Real estate, furniture, and fixtures.....		11,087,272
Current expenses and taxes paid.....		433,509
Gold coins and certificates.....	}	16,822,224
Silver coins and certificates.....		
Legal tenders and national bank notes....		
Checks and other cash items.....		
Other resources.....		2,949,767
Total.....		\$319,125,657
<i>Liabilities.</i>		
Capital stock paid in.....		\$36,355,769
Surplus fund.....		15,841,793
Other undivided profits.....		11,351,526
Dividends unpaid.....		581,255
Individual deposits.....		240,190,711
State, county, and municipal deposits.....		38,084
Due to other banks and bankers.....		5,606,897
Other liabilities.....		9,159,622
Total.....		\$319,125,657 (E. A. W.)

In the State of New York trust, loan, mortgage, security, guarantee or indemnity companies or associations and corporations or associations having the power of receiving money on deposit, incorporated under any law of the State, or corporations or associations not incorporated under the laws of the State which receive deposits of money or assume obligations in that State, other than banks, savings-banks and insurance companies, are on an equality in respect to the supervision the State exercises over them through its banking department.

(E. A. W.)

TRUSTS. The advantages to be derived from the principles of co-operation have in recent times impressed many changes on industrial methods, but none more striking than that exhibited by the great "Trusts" that have come into existence within a few years last past. That individuals may unite their property and exertions for their common benefit has always been recognized by our practice and our laws, although when they assume to act with corporate unity the authorization of the laws is a recognized necessity. Partnerships are the outgrowth of such purposes and in more advanced conditions of social integration a legal corporation makes its appearance, while it is reserved for a still more advanced state of industrial organization to exhibit co-operative groups embracing both individuals and corporations. The stages of this process present the most interesting social phenomena. (See CO-OPERATION and CORPORATION.)

Trusts in the sense of the term here used have existed in Europe for many years, but it was reserved for their transfer to the fertile American mind to produce their most striking effects. The necessity of bringing a series of railroads constituting parts of a particular system of transportation under a common management induced the formation of large "syndicates" for their control. The attempt that had been made to connect their operations by contracts imposing restrictions upon their management or combining their interests proving not to be effectual, proprietary combinations, aided by the functions of syndicates, were the result. This object was accomplished by uniting in the hands of a limited number of persons the major stock interest of each of the roads desired to be brought under a common management. Where the members of the syndicate were the owners of the stock interest that enabled them to assume management of the system the case was simply a combination among stockholders of a number of roads to exercise the rights they possess as stockholders to secure such management of such roads as might best suit their ideas of their interests. The idea, thus developed in its application to transportation, passed into the field of production.

The immense oil industry of this country attracted the attention of the large operators at first in its bearing on oil transportation, and afterwards extended to the production and refining of oil. (See PETROLEUM PIPE LINES.) So vast an enterprise demanded more than could be accomplished by the union of a limited number of capitalists having personal confidence in each other, and took a more enlarged form. The control of vast amounts of property consisting of oil wells, refineries, and means of transportation were to be centred for their management in the hands of a few men with the largest powers of control over the conduct of the business that it was possible to communicate. If the management was to embrace all the owners of the property, the vast extent of the business would demand that so large a number of managers should be included as to defeat that unity of purpose and action that is essential to the highest success. It was thus necessary that, while the ownership of the property managed should be in the hands of many persons, the control should be in the hands of a very limited number. To bring about this result the management had to be separated from the proprietary interest. Such a relation contained the essential principles of a trust according to which the title and control of property is in one while the beneficial interest is in the hands of another.

In the organization of the Standard Oil Trust in 1882 these conditions were complied with by an arrangement by which the property to be managed was transferred to certain persons termed trustees, but for the benefit of the actual owners whose interests were represented by trust certificates issued by the trustees and which were designed to be merchantable property

capable of being bought and sold in the market. The design appears to have been to place in the hands of the trustees property of partnerships, and the stock of incorporated companies engaged, in the business proposed to be carried on by the trust. The object of this arrangement was to enable the trustees to have the direct management of the property employed in the business by private companies and the indirect control of that held by corporations by having the right to choose directors for its management. This plan embraced several important features; it involved personal confidence in the trustees, who were intrusted with the largest powers of control over the property in trust capable of being communicated to persons standing in a fiduciary relation to its owners; it placed the vast industry in the hands of a limited number of persons whose skill and integrity were approved by a large number of interested persons qualified to understand the requirements of the business and the character of the men to whom it was intrusted. A more vigorous application of the principle of co-operation cannot be conceived.

The immense success of the Standard Oil Trust in embracing within its control almost the entire oil interest of the country attracted the attention of operators in other fields, and induced in 1884 the formation of the Cotton-Seed Oil Trust that has developed into a vast industry. Many other trusts have followed these examples, the most notable being the Sugar Trust.

It is supposed by many that these great trusts are in their constitution and operation out of harmony with the principle of our legal system. Others emphasize their conflict with competition, which seems to impress their minds as being the leading if not the only principle of the industrial system. A very general feeling prevails outside of the owners of the stock certificates that the powers placed in the hands of the trustees are too great for any class of men to exercise, whether they use them well or ill.

An intelligent view of trusts must distinguish among them and recognize very marked differences in structure and operation. Those trusts that deal with trade alone, independent of production and transportation, cannot in the nature of things have any other object than to stifle competition by direct action upon that principle. Such an attempt when accomplished by co-operation is condemned by our laws, in harmony with the principle of industry that the destruction of competition is not the proper function of co-operation. To aggregate capital for the purpose of trade is certainly legitimate, and to secure such aggregation of capital by uniting the means and exertions of a number of persons has always been regarded as conformable to both political and economic laws, as is apparent from the universal recognition of partnerships which are an instance of this class. While co-operation has a legitimate place in the operations of trade, it is an abuse of that function to employ it as means of stifling competition, and it is true that, whenever two or more persons unite for the purpose of trade, there is an indirect interference with competition, for had they traded separately there would have been competition between them, but if this is not the intended effect but an incidental consequence merely, the combination is not improper. An attempt to stifle competition in trade is then a wrong, whether committed by individuals trading together or by companies, whether organized on the principles of trusts or otherwise.

That trusts for such improper purposes have been created and have brought a bad name upon trusts in general is certainly true, and without doubt trusts organized for legitimate purposes have engaged in such transactions, but the question presented in such cases is not that of the legitimacy of trusts, but of the lawfulness of their conduct. The scarcity of commodities of general necessity is a social evil, and it takes no great penetration to discover that there are appropriate social means for preventing such an evil from

being intentionally created for the benefit of persons combining together to accomplish such a purpose. The legal principles that have led to the repression of such combinations are those just indicated, and their applicability to suppress such improper combinations cannot be affected by the form with which such combinations may be clothed. Where the object of a trust is an unlawful act the trust is incapable of being regarded other than as an unlawful combination, and that such trusts exist does not admit of question; many of the trusts that have brought discredit on the system are not only of this class but present most dangerous instances of such unlawful objects. Such trusts have been created to monopolize the food supplies of great cities like New York, and affecting as they do the necessities of life are deserving of the strongest condemnation.

The most interesting question as to trusts is not concerned with this class just indicated, but relates to such as tend to supply the means of production and transportation. While the trust that is merely a disguised attempt to monopolize trade must be judged according to its real rather than its pretended purpose, one that is actually intended to afford larger and better means of production and transportation must be judged by different principles. Such trusts may indirectly diminish competition, but if this is the incident or accident of their existence, their character is not to be determined by that fact.

It is the undoubted right of any number of persons, great or small, to combine their interests for purposes of controlling means for production, even although they should be able to grasp in their control the industry of the continent, and to deprive them of that liberty is to make an encroachment upon individual liberty as it is understood at this day in all free countries, while it is true that if the necessary consequences of such liberty should impair the social interests, it would be legitimate to place it under legal restraint, yet before such a step is taken its necessity should be demonstrated and not merely anticipated. If it is a right of individuals to co-operate thus, it is equally their right to repose the conduct of their interests in any person or persons in whom they may desire to place that degree of confidence. Whether they own factories or the stock of such as are incorporated, they have an equal right to unite with as many others as may choose to join with them and to commit the management of such property to persons of their own selection. The disposition that may be made by a stockholder of a corporation of his stock is no more the subject of legal control than is any other kind of property, and if he chooses to unite with others to use it as capital in productive enterprises he is at entire liberty to do so under our laws.

Whether viewed as a question of law or of economy, no limit has as yet been found to the possible aggregation of capital for industrial purposes; and if there is such a limit ascertainable, it has not been discovered by the experience of mankind; and unless such a limit is found and ascertained by laws, there can be no difference between the case of a single person trusting the management of his property to one in whom he has personal confidence and the case of such trusts on the part of any number of such persons.

The reduction of the number of persons producing a commodity has no necessary tendency to diminish the amount of that commodity produced, provided the reduced number have the means and desire of maintaining the supply, while, on the other hand, the less the number of persons producing a given amount of a certain commodity, the less should be the cost of its production. Over-production is a social evil, for although it may afford momentary gratification, yet in the end it will react against the social interests. Such a concerted management of an industry as will tend to prevent over-production must be regarded as a social advantage, and the organization of an industry as a

whole and bringing it under unity of control has a tendency in that direction. If this tendency is counteracted by other causes tending to unduly restrict production where there is concerted management of productive interests, that fact is yet to be demonstrated by actual experience. The tendency of social development seems to lie in the direction of the integration of industrial powers, and it is not yet clear where is to be the limit to such tendency, and to assume to fix an arbitrary limit before the true limit is ascertained is a step that no intelligent statesman will take.

The existing popular discussion of the question of suppressing or limiting the great trusts is of too excited a character to reach a safe conclusion. The conflict of individual interests has a conspicuous place in such discussion, and is not a proper element of the question as one of public law and policy. The concentration of capital necessarily displaces for the time being individual advantages, and causes popular opposition to new and advanced conditions. In the present instance this cause is more energetic from the influence of a widely extended opinion and feeling that the object of social arrangements should be to enhance the powers of the individual by a corresponding decrease of the influence of corporate and aggregate masses. It is not to be expected that a safe solution of either the theoretical or the practical question suggested will be reached while these elements are combined in public discussion.

If it is perceived that the principles that have been stated in relation to productive industries are sound and applicable to the case, it will readily appear that they are of equal force in their application to the conditions of transportation. Although trade and transportation are embraced in the distributive function that intervenes between production and consumption, still they are separated by distinct principles. That railway transportation demands concentrated management is generally admitted, many persons believing that that need cannot be satisfied otherwise than by placing the entire system in the hands of the government, while others regard that end as attainable by combined individual efforts.

It is equally true of transportation as of production, that the proper relation between supply and demand is a social need, and that it can be better reached by concerted management than by ordinary competition. What has been said of productive industry on this subject needs no demonstration as to its applicability to the case of transportation.

It must be conceded by every intelligent thinker that dangers attend the existence of great powers, increased with the increasing magnitude of those powers. Our experience with steam at high pressures and with electricity demonstrates this fact, and that such dangers are incapable of being separated from the conditions of material progress. When it is ascertained how far the development of material resources should be permitted to go, a limit of the measure of the productive powers can be determined, but not until that time arrives can such limitations be intelligently imposed. America has the rôle of competition with Europe under conditions that render the highest organization of its productive powers a necessity and cannot afford to weaken the sources of its strength, and should not be hasty in imposing political restraints upon the free exercise of its productive powers.

If the great trusts confine their operations within the limits of a wise administration, they may prove to be a great step in advance of the realizations of industry in the past; but if they abuse their powers and seek to inconvenience rather than to serve the community, the failure of the system will be due to their own fault, and in the meantime the policy of the country is to keep them within the line of their proper function, and not to impair or destroy their useful powers. (See CORPORATION.) (A. J. W.)

TRUXTON, THOMAS (1755–1822), naval officer, was born Feb. 17, 1755, at Jamaica, Long Island. At the age of 12 he went to sea and was impressed on board a British war-ship. In 1776 he was lieutenant of the privateer Congress, and next year was commander of the Independence and, in company with two consortships, succeeded in making many prizes. On the conclusion of the war of independence he engaged in mercantile pursuits, trading between Philadelphia and the West Indies. In 1794 he was promoted captain of the West Indies squadron and given command of the frigate Constellation, on board of which he did efficient service during the trouble with France, in Pres. Adams' administration. In especial, in January, 1799, he captured, off St. Kitts, L'Insurgente, the swiftest craft in the French fleet, for which exploit he received a service of plate from the merchants at Lloyd's. Next year he encountered the French frigate Vengeance off Guadeloupe and drove it, in a hopelessly damaged condition, into Curaçoa. But for the fall of his foremast he would have captured her. For his gallantry here Congress voted him a gold medal. In 1801 he was promoted commander of the West Indies squadron and transferred to the President. In 1802 he was named to command the expedition against Tripoli, but being denied a captain to his flagship he declined to accept and Jefferson struck his name off the navy-list. He now retired to private life in Philadelphia, where he occupied the position of high sheriff from 1816 to 1819. He died May 5, 1822. He was author of a work on *Latitude and Longitude* (1794), and compiler of a volume of extracts on *Naval Tactics* (1806).

TSCHUDI, JOHANN JAKOB VON, Swiss naturalist and traveller, was born July 25, 1818, at Glarus, Switzerland, of a family distinguished for talent in many directions. For its earlier members of note see the *ENCYCLOPÆDIA BRITANNICA*. He studied at the University of Zurich, and afterwards at those of Leyden, Paris, and Berlin, devoting himself chiefly to the natural sciences and philology. In 1838 he set out on a French ship with the view of making a journey round the world, but the captain having sold the vessel at Callao, he was compelled to restrict himself to an investigation of the natural history and ethnography of Peru, which he pursued for five years. On his return to his property at Jakobshof in Lower Austria, he devoted some years to the arrangement of his materials to supply the leading museums of Europe. In 1857 he undertook a second journey to Brazil, the Argentine States, Chili, Bolivia, and Peru, returning in 1859, when he was almost immediately sent back by the Swiss government as its minister extraordinary to Brazil. During the two years he acted in this capacity he directed his attention particularly to the capabilities of the country as a field for immigration. In 1863 he was appointed plenipotentiary to Vienna and remained there till 1883, when he returned to his property. Among his works on natural history are his *Système de Batrachier* (Neuchâtel, 1838), and *Untersuchungen über die Fauna Peruanas* (St. Gall, 1844–47). His philological works comprise *Die Kechua Sprache* (Vienna, 1853); *Ollanta*, an old Peruvian drama translated out of the Quechua tongue and annotated (Vienna, 1875), and his elaborate *Organismus der Kechuasprache* (Leipzig, 1884). His works of travel, embodying his observations in Brazil, the Argentine Republic, Chili, Bolivia, and Peru, are of great value, and have been translated into English. He has also published a number of papers on natural history, medical, geographical, and ethnographical subjects.

TUCKER, ST. GEORGE (1752–1827), jurist and founder of an influential Virginian family, was born in Bermuda, July 9, 1752. His father came to Virginia while St. George was yet a boy, and he entered William and Mary College, where he graduated in 1772. He afterwards studied law, which he administered as a

magistrate almost from his admission to the bar. On the outbreak of the war of independence, he left the courts and took up arms for his adopted country. His chief exploit was a secret and successful expedition to Bermuda, where he knew there was a large quantity of military stores in a fortification slenderly garrisoned. These stores eked out the slender supply of Washington's army in the siege of Boston. Tucker was with the army before Yorktown in the capacity of lieutenant-colonel, and received a wound in the face from the explosion of a bomb. He was soon after appointed to a seat in the General Court, and, while a judge, was professor of law in William and Mary College. In 1803 he was advanced to judge in the State Court of Appeals, holding the office for 8 years; in 1813 he became judge of the U. S. Court for the eastern district of Virginia. He took part in codifying the laws of his State, and was one of the commissioners of Virginia who met in Annapolis in 1786 and recommended the convention that formed the present Federal Constitution. In 1778 he married his first wife, Mrs. Randolph, mother of John Randolph of Roanoke, by whom he had numerous descendants, not a few of whom have risen to eminence. His second wife left no children who survived him. Judge Tucker had a ready talent for versification which he exercised through life, being particularly successful in *vers de société*. To his annotated edition of *Blackstone's Commentaries* (1803) is probably due his sobriquet of the "American Blackstone." He was also the author of *A Dissertation on Slavery, with a Proposal for its Gradual Abolition in Virginia*. He died in Nelson county, Va., in 1827.

His son, HENRY ST. GEORGE TUCKER (1781–1848), was born in Virginia, Jan. 5, 1781, studied law under his father and became like him eminent in his profession. He was professor of law in the University of Virginia, and chancellor of the fourth judicial district and president of the State Court of Appeals. From 1815 to 1819 he was a member of Congress. His works include *Lectures on Constitutional Law; Commentaries on the Laws of Virginia* (2 vols., Winchester, 1836); and *Lectures on Natural Law and Government* (Richmond, 1843). He died at Winchester, Va., Aug. 28, 1848.

Another son, NATHANIEL BEVERLEY TUCKER (1784–1851), was born at Matoax, Amelia co., Va., Sept. 6, 1784. Graduating at William and Mary College, he studied law, and commenced practice in 1809 in Charlotte co., but removed in 1815 to Missouri where he became a judge, retaining office till 1830. In 1834 he was called to the chair of law in William and Mary College, and held this position till his death, which occurred at Winchester, Aug. 26, 1851. In 1850 he had attended the Southern convention at Nashville, and in discussing the alleged wrongs of the South delivered an elaborate invective which recalled the speeches of his half-brother, John Randolph of Roanoke. His friend, W. Gilmore Simms, has well described him as "a brave old Virginian gentleman, a stern States Rights doctrinaire, intense of feeling, jealous of right, and with an eager sense of wrong and injury." Judge Tucker's legal works include a treatise on *Pleading* and *Lectures on Constitutional Law*, which are still of value as giving clearly and forcibly the States Rights view. Besides these he was the author of three novels, *George Balcombe*, *Gertrude*, and *The Partisan Leader*. The last, secretly printed in 1836, but purporting to have been written in 1850, has a special interest as in some measure foreshadowing the secession movement. It represents Van Buren as in 1849 holding a third presidential term, at the head of a strongly centralized government. The Southern States, however, except Virginia, have seceded; the Constitution having been set at naught, the Union has been dissolved, and a conflict of small republics ensues. These were depicted as the legitimate consequences of the continuance of Van Buren's ad-

ministration, and though strangely at variance with the actual facts, reveal the ideas then germinating in the leading classes of the South. The story was reprinted in New York in 1861 with the title, *A Key to the Disunion Conspiracy*.

GEORGE TUCKER (1775-1861), a nephew of St. George Tucker, came to Virginia from the Bermudas about 1787, entered in William and Mary College, and was educated in law by his uncle. He was elected to Congress in 1819, 1821, and 1823, and in 1825 became professor of ethics and political economy in the University of Virginia, which position he held till he reached his 70th year. The most important work that came from his pen was a *Life of Thomas Jefferson* (1837), which was long a standard authority. He was the author also of a novel entitled *The Valley of the Shenandoah* (1824); and *A Voyage to the Moon* (1827), a satirical romance. His *History of the United States* (4 vols., 1856-58) brought the narrative down to 1840. The most of his later life he spent in Philadelphia, but he died near Charlottesville, Va., April 10, 1864.

TUCKERMAN, HENRY THEODORE (1813-1871), man of letters, was born in Boston, April 20, 1813, and educated in the public schools there. The years from 1833 to 1839 were spent in European travel for the sake of his health, with the exception of parts of 1835-36, when he returned to resume his studies. The fruits of his tours are seen in his *Italian Sketch-Book* (1835); *Isabella of Sicily, a Pilgrimage* (1839); *Rambles and Reveries* (1841), with which may be associated his later *Month in England* (1853) and *Maga Papers about Paris* (1867). Removed from Boston to New York in 1845. He contributed there largely to magazines, reviews, and other periodicals. In 1846 the first series of his contributed papers appeared in collected form under the title, *Thoughts on the Poets*, and they were followed by *Artist Life, or Sketches of American Painters* (1847); *Characteristics of Literature* (1849-1851); *The Optimist* (1850); *Diary of a Dreamer* (1853); *Essays, Biographical and Critical, or Studies of Character* (1857). Of this last volume Washington Irving, with characteristic kindness to a brother author, says: "I do not know when I have read any work more uniformly rich, full, and well sustained." In biography proper he produced the lives of Commodore Silas Talbot, Horatio Greenough, Dr. J. W. Francis, J. P. Kennedy. Part of his essay on *The Character and Portraits of Washington* (1859) was originally appended to Irving's *Life of Washington. The Book of American Artists* (1867) is still a standard work, and, with his other writings on art, furnishes his best claim to remembrance. While steadily diligent with his pen, he was always somewhat of a dreamer, and the ideal unworldly life of the artist had especial charms for him. To Shaw's *Outlines of English Literature* Tuckerman appended a *Sketch of American Literature* (1852). His pamphlet on *The Rebellion, its Latent Causes and True Significance* (1861), was pronounced by Dr. A. P. Peabody "a very thorough and careful analysis of certain secondary causes of the Rebellion." Among his other publications are *America and her Commentators* (1864) and *The Criterion: or the Test of Talk about Familiar Things* (1866). Tuckerman also produced *The Spirit of Poetry* (1851) and *A Sheaf of Verse*, the latter a contribution to the Sanitary Fair of New York in 1864. His books are mainly collections of monographs relating to biography, literature, and art. As specimens of genial and pleasantly instructive, but not profound, criticism they served well a temporary purpose, though now less frequently read or quoted. The author deserves credit for his genuinely American spirit.

TUCSON, a city of Arizona, county-seat of Pima co., is on the Rio Santa Cruz and on the Southern Pacific Railroad, 250 miles E. of Yuma. It has a court-house, U. S. government building, a bank, a church, public and private schools, and a newspaper

office. It carries on trade in hides, stock, wool, and gold-dust. It was founded by the Jesuits in 1560, and was the capital of Arizona from 1867 to 1877. Its population in 1880 was 7007.

TUFTS COLLEGE is situated on the most beautiful and commanding eminence in the southeasterly part of Middlesex co., within the town of Medford and on the borders of Medford and Somerville, Mass. The tract of land given by Mr. Charles Tufts comprises in all 100 acres. In consequence of this gift it was determined that the college should bear his name. The original charter, granted April 21, 1852, conferred the power to give degrees of every kind "except medical degrees." This restriction was removed Feb. 2, 1867. In May, 1853, the Rev. Hosea Ballou, D. D., was chosen to the office of president. The college was first regularly opened to students in August, 1855. Dr. Ballou died in May, 1861. The Rev. A. A. Miner, D. D., was chosen to succeed him in 1862, and continued to hold the office until his resignation in February, 1875. During his presidency and largely through his instrumentality the extraordinary material development of the college was secured. Funds were obtained from Silvanus Packard, William J. Walker, Oliver Dean, and others, aggregating fully \$750,000. The Hon. Israel Washburn, Jr., the war governor of Maine, was chosen president on the resignation of Dr. Miner, but he declined to accept the office. The trustees then determined to place an alumnus at the head of the institution. The present incumbent, the Rev. Elmer Hewitt Capen, D. D., a graduate of the class of 1860, was elected to the vacant chair, March 13, 1875. The calling of an alumnus to the post has quickened the interest and secured the co-operation of the graduates.

In the matter of development few institutions in the country have made steadier progress. The selection of its present site was fortunate: first, because of its proximity to Boston, the literary centre of the New World; and, secondly, because of the closeness of its proximity to Harvard University, which has compelled it to maintain the highest standard. The result is seen in the steady growth of recent years. The attendance has increased about forty per cent. during the last decade.

The course of study adopted was that of the other leading New England colleges. The faculty in the beginning consisted of three professors besides the president; and for some years the work was done by not more than five teachers. The gifts of Dr. Walker enabled the trustees to enlarge on the side of science. A professorship of civil engineering was created in 1867. This department has been enlarged gradually, until now men receive complete courses of professional instruction in civil, mechanical, and electrical engineering. Natural history, physics, and chemistry have each been made separate departments. There are excellent laboratories of physics, and, besides college work, original investigations are conducted by Dr. Dolbeare and assistant-professor Hooper. The organic research laboratory of chemistry has been fully equipped and offers facilities unsurpassed for original investigation. Very considerable additions to chemical knowledge are made every year by Prof. Michael and his assistants.

Previous to 1875 the work of the college was mainly prescribed. At that time the scope of electives was broadened. There are now 11 full courses of electives open, and from the middle of junior year a large percentage of the work is in lines which the student chooses for himself. A system of honors has been devised to reward students eminent in special lines of work. The degree of A. M. is given only after graduate study in residence or under the direction of the faculty for at least one year. The modifications of discipline have been no less important. Formal rules relating to conduct have been abolished. Men are put upon their honor and no longer watched. Under

this policy the moral tone of the college has greatly advanced. The contentment of students has also increased. The relative percentage of those who graduate to those who enter has risen from 63 per cent. to nearly 80 per cent., placing it in this respect in the front rank of New England colleges. The whole number of graduates is now about 500.

Silvanus Packard by will provided for one theological professorship. Thomas J. Sawyer, D. D., was elected Packard professor of theology and the divinity school organized and opened in 1869. There are at present four professors in the divinity school besides Dr. Sawyer. The course of study is four years for all except college graduates.

The site of the college was originally treeless and barren. But imposing buildings have been erected, walks and driveways have been constructed, and trees have attained a thick and heavy growth. There is no more attractive spot in the neighborhood of Boston. In 1883 Mrs. Mary T. Goddard erected at her own cost a beautiful stone chapel, and on its completion built and furnished an excellent gymnasium. One of the most important additions of recent years is the Barnum Museum of Natural History, the gift of Mr. P. T. Barnum. It is a building of dignity and beauty. The first floor is devoted to laboratories and work-rooms. The main floor has a lecture-room and a grand vestibule in which the larger specimens of natural history are deposited and where the stuffed skin of Jumbo is to find its ultimate resting-place. The third floor comprises a large exhibition hall for the cabinet, together with the fine zoological collection given by Mr. Barnum. The library contains nearly 25,000 bound volumes, many of them rare and of great value, and 8000 or 9000 pamphlets.

The college has been distinguished for its liberal policy towards young men who are obliged, on account of limited means, to struggle for an education. There are thirty scholarships in the gift of the college. By means of these tuition may be cancelled. Gratuities are also given, in cases of need, so that instruction is practically free to men of promise and fidelity whose circumstances require it. On account of the isolation of the college, there being no villages in immediate contact with it on either side, it is not only extremely favorable to study, but admirably adapted to those who are obliged to practise economy. (E. H. C.)

TULIP TREE, or TULIP POPLAR, the common name given to the *Liriodendron tulipifera*, a genus of trees belonging to the order *Magnoliaceæ* which has but one species, that above named. It is a native of the United States, where it is generally known as a poplar from its resemblance to the latter, though it has no affinity to the poplars. It is known as white wood and yellow poplar, from its varying color; as canoe wood, from the use made of it by the Indians; and as saddle tree, from the shape of its leaves. It is one of the most magnificent of American deciduous trees, being only surpassed in size by the plane or butternut, and being superior to the latter in the perfect straightness and uniform diameter of its trunk, the more regular distribution of branches, and the greater richness of foliage and flowers. Its height is usually 60 to 80 feet, with a diameter of 18 inches to 3 feet, but in favorable localities it may attain a height of 120 to 140 feet, and more than 7 feet diameter. The leaves of this tree have a peculiar development. As the large buds open, the leaf group is found to be covered by two stipules cohering at their edges so as to form a sac. On opening they reveal an interior sac of the same character and a single leaf closely folded and with the petiole doubled over. As this leaf unfolds the interior sac opens, revealing similar conditions within, and this process continues until 5 or 6 leaves have appeared. The leaves are 6 or 8 inches long, on long petioles, with four lobes, the apex appearing as if abruptly cut off, leaving a very broad, shallow notch. This conformation of the leaf gives a

peculiar appearance to the tree, clearly distinguishing it from all others. The flowers are equally peculiar and striking. They have 3 deciduous sepals and 6 petals, forming a large lily or tulip shaped flower, from which resemblance both the generic and specific names have been derived. The flowers are solitary and terminal, inclosed by a sheath which is pushed off as they open. The flower bell is 2 inches or more in length, with numerous stamens and a cone-like mass of pistils. The petals are greenish-yellow in color, with an orange spot at base, the color deviating in different localities. They form large, showy flowers with an agreeable odor and much nectar, which when in bloom add greatly to the ornamental character of this handsome tree. The fruit comprises numerous thin scales attached to a common axis and forming a conical spike 2 or 3 inches long.

The range of the Tulip tree is from the Southern extremity of Lake Champlain to the Gulf States, and from the Connecticut River to the Mississippi Valley, being abundant in the Middle and Western States, and particularly so in Kentucky. It delights in deep, loamy, and extremely fertile soils, like those of rich river bottoms and swamp borders, but will grow on soil of different character. The wood, though classed with the light woods, is much heavier than the common poplar and has almost as many uses as the white pine. It is easily worked, polishes well, and the heartwood when well seasoned resists decay and is rarely attacked by insects, but is liable to shrink and warp when exposed to the weather. Its color and character are so affected by the nature of the soil that it is known in some localities as white, in others as yellow poplar. Near New York and Philadelphia it was formerly much used for joists and rafters, but has grown scarce and has been replaced by pine and spruce. It is also used for door-panels and wainscots, and particularly for carriage-panels, it taking the paint well and polishing brilliantly when perfectly dry. Large quantities are used in trunk-making, for chair-seats, and for tables and beds (stained to imitate mahogany). Of other uses may be named the making of sleigh- and wagon-bodies, bowls, brush- and broom-handles, and various other articles of turners' ware. The Indians used it to form canoes, the wood being light and strong, while from the great length and diameter of the trunk single canoes could be made capable of carrying 20 or more persons. The bark, especially of the root, is bitter and aromatic, and is considered by some as scarcely inferior to cinchona as a tonic and antiseptic. The aromatic principle resides in a resin, which acts as a gentle cathartic. The bark was used by the Indians as a remedy for intermittent fevers. Reduced to powder and given to horses it seems a pretty certain remedy for worms. (C. M.)

TUNNELS IN AMERICA. This country has several prominent examples of tunnels. See Vol. XXII. through mountains for railroad and p. 622 (p. 662 mining purposes, and has also begun to use tunnels under the beds of navigable rivers. In the first class the Hoosac tunnel is the most noted. The Hoosac Mountain is a part of the Green Mountain range that extends across the western part of Massachusetts. On account of the very circuitous routes which it compelled to be taken between Boston and Albany, and the West, the project of a shorter communication was seriously debated in the early part of the present century. At that time canals were in vogue, and in 1825 the State of Massachusetts appointed a board of commissioners to select a route for such canal to connect Boston with the Hudson River. Their report included the project of a tunnel through the Hoosac Mountain. But when soon afterward the early railroads of America proved successful, the scheme of building a canal was abandoned. The Boston and Albany Railroad was completed in 1842; it was carried over the mountains about 20 miles to the south of the proposed tunnel. The steep grades of

this road had been attempted by no road up to that time; and even yet the running expenses and freight charges are higher than they would be with lower grades. On this account the project of the tunnel was still considered seriously even after the canal had been abandoned. In 1848 the Troy and Greenfield Railroad Company was incorporated with the object of building a road through the mountain. The most eminent geological authority of that day, Prof. Edward Hitchcock, of Amherst College, examined the mountain, and stated that quartz and mica slate were the chief substances to be encountered. In 1851 the work upon the tunnel was commenced with a clumsy and expensive boring machine, which attempted to bore a hole of the full size of the tunnel. When this and similar machines had proved failures the work was abandoned until 1854. The State of Massachusetts then loaned \$2,000,000 and took a mortgage on the property of the company as security. From this source funds were obtained until 1862, when the work, again stopped, and the State foreclosed the mortgage. The State having committed itself to the work commissioners were appointed to carry it on, but on account of its slow progress the State, in 1868, made a contract for its completion. At that time the work was in the following condition: East end, 5283 feet; west end, 4055 feet; west shaft sunk to grade, 318 feet, and central shaft sunk to a depth of 583 feet. The contract required the completion of the additional 15,743 feet, the central shaft to be sunk to grade, and the sum to be paid, \$4,594,268. The work was successfully prosecuted; and on Feb. 9, 1875, the first railroad train passed through the Hoosac Mountain.

Down to 1865 the drilling and blasting had been done by old methods; after that date the State commissioners used machine-drills driven by compressed air, as had been successfully done in the Mont Cenis tunnel under the Alps. For using compressed air sufficient water-power was obtained at the east end; while the central and west end sections were carried on with steam-power. The first drills were heavy and expensive; and later a less complicated and lighter machine, with a gang of drills, was used. With this machine a hole of from 4 to 5 feet in depth could be made in an hour; and one of the drills was kept running for over 3 months without the slightest repair, during which time the total depth of holes drilled would have measured over a mile in length. The compressed air was stored in a tank and conveyed to the tunnel through 12-inch iron-pipes carrying a pressure of about 60 lbs. to the square inch. A rubber-pipe, easily disconnected when the drill-carriages were taken out of the way of a blast, connected the iron-pipes with the drills. A heading, 8 feet high by 24 feet wide, was driven by the first gang. About 500 feet in the rear of this another gang was employed in enlarging the tunnel to the full size of 22 by 24 feet. The average number of men employed was from 500 to 800, and 136 lives were lost during the construction. Work was carried on continually night and day, with the exception of Sundays. Down to 1865 the chief explosive was the ordinary black powder; but after that date nitro-glycerine was used for a short time, and it was finally decided to use trinitro-glycerine manufactured upon the spot. The central shaft, located near the centre of the tunnel, is 1028 feet deep. This was sunk not only as a ventilator, but also as a means of shortening the time of the work by allowing other gangs to work east and west from its bottom. After sinking to the tunnel-grade an advance was made to the west of 2006 feet, and to the east of 1563 feet. But so much water poured into the tunnel that it is doubtful if much time was saved in this way. After the sinking of the central shaft it was thought best to sink a shaft toward the western entrance, on account of the uncertain structure of the rock in that part of the tunnel. This also helped to shorten the time of the work. After the tunnel had been projected monu-

ments were built upon the points of the two highest summits overhead. The transit instrument threw these monuments in line and extended the line in either direction for several miles. This not only furnished the line upon which the tunnel was constructed, but also the line by which the central and western shafts were sunk. When the headings from the central shaft and from the eastern opening came together their alignments swerved from each other by only $\frac{1}{8}$ inch; whereas, the opposite arms of the Mont Cenis tunnel had a divergence of more than half a yard.

The tunnel cost the State of Massachusetts, with interest on the investment, about \$18,000,000; but the cost would not have been so great had the improved methods of machinery and blasting been used earlier in the progress of the work. The first plan for the use of the completed tunnel was to allow all railroads to have equal rights; but this was soon abandoned, and special privileges were given to one line. After several years of unsatisfactory dealing the State of Massachusetts, in January, 1887, completed the sale of the Hoosac tunnel, with the accompanying 44 miles of railroad, to the Fitchburg Railroad Company for \$5,000,000 in bonds and \$5,000,000 in stock of the railroad.

In June, 1888, a tunnel was opened through the Cascade range in Washington Territory. The work was begun in April, 1886; the material and machinery were hauled in wagons for over 90 miles through a rough country without roads; some of the heavy machinery was moved by block and tackle the whole distance, and \$125,000 had been expended before the actual work began. The tunnel is 9850 feet long and 16 feet wide by 20½ feet high in the clear. It is intended for a single-track road. The west end approach consists of an open cut through trap-rock, while the east end enters the tunnel by crossing a creek immediately under a cataract, which has a fall of 160 feet. Before crossing this creek the track is made by cutting a heavy ridge or slide of earth and loose rock. These two approaches contained in the aggregate upward of 30,000 cubic yards of material, most of which was solid rock, requiring to be blasted. The strata or formations of the mountain lie nearly flat, having but a slight inclination from east to west across the entire range. This increased the danger and difficulty of the work. The rock throughout was a gray conglomerate basalt of medium hardness, but slacking and sealing on exposure to air, rendering timbering necessary. The work was constantly prosecuted from both ends with the most approved machinery; one of the air compressors was run by water-power, and the other by steam. The tunnel was run without the use of air-shafts.

Tunnels for mining purposes are less frequent than railroad tunnels. They are used to reach deposits of gold and silver, and also to drain the mines. One of the more recent enterprises is the Big Bend tunnel of Butte co., Cal. Certain points in the valley of the Feather River having been found to be unusually productive of gold, it was considered most desirable for economy's sake to connect these points. To this end a tunnel was commenced in 1882, and completed in 1887. It practically diverts at will the whole of the river from its present channel, and carries it through a mountain. Six gates of iron and steel, each 4½ by 8 feet, at the head of the tunnel, control the passage of the water. The size of the tunnel is 12 by 16 feet, and the length is over 2 miles.

River Tunnels.—Small tunnels under navigable streams are quite frequent in the United States. In Chicago a number have been bored under the Chicago River in order to connect the several parts of the city without bridges. The project of a tunnel under the Detroit River, through which railroad traffic should be carried without interfering with navigation, has long been discussed. Various towns have, from time to time, been selected as sites for the beginning of operations.

At Port Huron, some miles above Detroit, the River St. Clair is now being tunnelled in order to avoid the carrying of cars upon railroad ferry-boats. When completed, the tunnel will shorten the distance between Buffalo and the cities of Detroit and Chicago. It will be over a mile in length, 2340 feet being under the river, 1810 feet under dry ground south of the city limits of Port Huron, and 1160 feet on the Canadian side; 1500 feet of the portion under the river will be almost level, falling eastward only enough to cause the water that leaks into the tunnel to run to the Canadian side. The total length of the ascent on the American side will be 4900 feet, and on the Canadian side 4970 feet. The length of the open cutting or approach at the Port Huron end of the tunnel will be 2820 feet, and at the Canadian end 3270 feet. The depth of the lowest part of the tunnel below the surface of the water will be 81 feet, which is 15 feet higher than had been at first expected, on account of anticipated quicksands and water-pockets. The minimum depth of the top below the bed of the river will be 15 feet. The tunnel has a clear internal diameter of 20 feet, and is intended for a single track. A double-track tunnel was at first proposed, but it was found that two single-track tunnels could be built at less expense than one double-track. Should this tunnel prove successful and profitable, the company intends to build a second one. The cost of the tunnel is estimated at \$1,500,000.

There have been various projects of tunnels around New York city. One passing under the East River is projected between Grand Street and the eastern district of Brooklyn; in another, from Long Island City, the eastern entrance of the tunnel would be nearly $\frac{1}{2}$ mile from the river, and the western terminus near Tenth avenue and Thirtieth street. The depth below the surface of the water would be about 100 feet, rising to the surface under either city at an inclination of about 60 feet to the mile. The intended width of the tunnel is 27 feet and the height 21 feet. A double-track road will be laid, each track to be a continuous rail, to prevent noise and jarring. The proposed trains are to be operated by electric motors, and the tunnel lighted by electric lights and ventilated by steam-fans. At each station elevators capable of holding 100 passengers would connect with the surface and elevated railroads.

Another tunnel is proposed under the Harlem River, at the northern end of New York city, in order to avoid the delay occasioned by the opening of the draw-bridges. The construction of this tunnel presents, from an engineering point of view, few difficulties. As the depth of water at the maximum is 30 feet, there would be but 54 feet of vertical altitude to be overcome in the gradients of the tunnel approaches, and this could be done by a grade of 200 feet to the mile which would be perfectly practicable for the use of horse-cars and teams. Ten feet is considered sufficient headroom for the tunnel, as has been ascertained in the Chicago experience. But although a grade of 200 feet to the mile is of no serious moment in the operation of horse-power, yet in the case of steam-railroads, especially those which transport heavy freight, high grades add to operating expenses in a largely increasing ratio. To lessen this grade to a more practicable one, the approaches would have to be carried back a long distance, which would greatly increase first cost and would introduce other difficulties.

The project of connecting New Jersey with New York city by a tunnel has often been discussed, because it would facilitate the passage to Philadelphia and other important points. The tunnel started under the Hudson in 1874-5 by Col. Haskins, of New York, was abandoned after the expenditure of over \$1,000,000. Although the Pennsylvania Railroad Company has control of the charter under which this tunnel was to be constructed, and which gives the owner the right to go underground to any portion of New York or Brooklyn, the old tunnel will not be utilized. By a new project

the underground work will be upon different principles, and will comprise two single-track tunnels. As the expense of this operation will be stupendous, it is proposed to make all railroad lines entering Jersey City parties to it. The plan contemplates terminals, under Washington Square, in New York city, at a depth of 15 feet below the earth's surface, which will occupy an area of over an acre of space. This will be illuminated by electricity and furnished with every convenience and comfort for travellers. There is an evident tendency toward the introduction of underground railroads in the larger American cities, and it is probable that in a few years some of the various schemes proposed for passenger and freight railroads of this character will be successfully executed. (F. G. M.)

TUPELO. See GUM TREE.

TUPPER, MARTIN FARQUHAR, author, was born in London, July 17, 1810, and educated at the Charterhouse, and at Christ Church, Oxford, graduating 1832. He was called to the bar at Lincoln's Inn, but never practised, and has lived on his estate of Alburg in Surrey. His literary career began with an anonymous volume of poems in 1832. His reputation was made by *Proverbial Philosophy* (1838), which the *Athenæum* thought not "likely to please beyond the circle of a few minds as eccentric as the author's." The critic was mistaken; of this and the second series, 1842, the hundredth thousand was issued in London, 1865, and more than half a million copies have been sold in America. The book has had the honor of several French translations. A third series appeared 1867, and was denounced by the *Athenæum* as "weak, twaddling, and insincere, not sharp or clear, but serpentine, flabby, and obscure." Mr. Tupper's other works are very numerous but less notable: they include several novels. *The Crock of Gold* (1844); *Heart* (1844); *The Twins* (1844); and *Stephen Langton, or the Days of King John* (2 vols., 1858); of miscellaneous prose, *Modern Pyramid* (1839); *An Author's Mind* (1841); *Probabilities* (1847); *Farley Heath* (1851); *Paterfamilias' Diary* (1855); *Memoirs of W. G. Tupper* (1856); and *Rides and Reveries of the late Mr. Esop Smith* (1857); and in verse *Geraldine* (1838); *A Thousand Lines* (1845); *Hactenus* (1848); *King Alfred's Poems in English Metres* (1851); *Hymns for all Nations* (translated into 30 languages, for the World's Fair, 1851); *Lyrics* (1854); 300 *Sonnets* (1860); several volumes of ballads, a few odes, etc., and two plays, *Alfred* (1865) and *Raleigh* (1866). The *Times* in 1870 accorded him the long established "position of chief butt for metropolitan critics and professional jokers;" but the *Literary Gazette* in 1848 called him "a genuine poet and an original thinker," and his admirers proposed a testimonial in 1867. Mr. Tupper's life has been uneventful; he visited America in 1851, and was at one time talked of for a baronetcy. He published *My Life as an Author* (1886). Of late his circumstances are said to have become reduced.

TURNER, SAMUEL HULBEART (1790-1861), theologian, was born at Philadelphia, Jan. 23, 1790. He graduated at the University of Pennsylvania in 1807 and was ordained to the Protestant Episcopal Church in 1811, becoming priest in 1814. He had charge of a church at Chestertown, Md., for five years, and in 1818 was elected professor of historic theology in the General Episcopal Seminary, New York. He remained in connection with this institution until his death, though he was transferred to the professorship of Biblical learning and interpretation of Scripture in 1821. He also held a professorship of Hebrew in Columbia College from 1831. He died Dec. 21, 1861. He translated Jahn's *Introduction to the Old Testament* and published notes on some books of the New Testament; *Biographical Notices of Distinguished Jewish Rabbis* (1847); *Scripture Prophecy* (1852); *Teachings of the Master* (1858); *Spiritual Things compared with Spiritual* (1850). He had also contributed to

leading theological reviews and other periodicals and left some manuscripts nearly ready for the press. His *Autobiography* was published in 1862.

TURNER, WILLIAM WADDEN (1810-1859), philologist, was born in London but emigrated to the United States in 1818, and learned the printer's trade. He became distinguished for his knowledge of ancient and modern languages. He was appointed librarian to the University of New York, and in 1842 instructor in Hebrew in Union Theological Seminary. In 1852 he removed to Washington to become librarian of the Patent Office, and died there Nov. 29, 1859. He had assisted in preparing Dr. Nordheimer's Hebrew text-books, and in translating Freund's *Latin-German Lexicon* as a basis of Prof. E. A. Andrews' *Latin Dictionary*. He devoted considerable attention to the languages of the American Indians and contributed to the linguistic publications of the Smithsonian Institution.

TYLER, WILLIAM SEYMOUR, educator, was born at Hartford, Pa., Sept. 2, 1810. He graduated at Amherst College in 1830, and studied theology at Andover and was tutor at Amherst. In 1836 he was licensed to preach by the Third Presbytery of New York, but, being made professor of Latin and Greek at Amherst, he devoted himself to teaching. In 1859 he was ordained by a Congregational council, and thereafter preached occasionally in the college chapel and in various churches. He has published several scholarly text-books—*Tacitus' Germania and Agricola*; *Tacitus' Histories*; *Plato's Apology and Crito*; *Plutarch on the Delay of the Deity*; *Demosthenes De Corona*; *Demosthenes, Philippics and Olynthiæ*; *Homer's Iliad*. He has published an essay on *Prayer for Colleges* and a *History of Amherst College* (1873), and *Theology of the Greek Poets* (1867).

TYLOR, EDWARD BURNETT, English anthropologist, was born at Camberwell, Oct. 2, 1832. He devoted himself to the study of the races of men, their history, speech, and civilization. In 1871 he was chosen a fellow of the Royal Society, and in 1883 was appointed director of the University museum in Oxford, where he also delivers lectures. He is also president of the Anthropological Society. His publications are of the highest authority in his department of research. Among them are *Anahuac, or Mexico and the Mexicans* (1861); *Researches into the History of Mankind* (1865); *Primitive Culture* (2 vols., 1871); *Anthropology, an Introduction to the Study of Man and Civilization* (1881).

TYNDALL, JOHN, British physicist, was born at Leighlin-bridge, Ireland, in 1820. Although his parents were very poor he received a good elementary English and mathematical training, and at the age of 19 became a civil assistant in the division of the Ordnance survey which included his native village. In 1844 he was employed by a firm in Manchester and took part in railway engineering operations. In 1847 he became a teacher in Queenwood College in England, which was intended to give preliminary technical training to engineers and agriculturists. Here he became associated with the chemist Dr. Frankland, and entered on a series of physical investigations which have led to momentous results. The two friends, in furtherance of their work, in 1848 went to the University of Marburg, where they studied under R. W. Bunsen (q. v.). Afterwards Tyndall went to Berlin to work in the laboratory of Magnus. His researches had especial reference to magnetism and diamagnetism. His publications caused him to be chosen a fellow of the Royal Society, and in 1853 he was chosen to succeed Faraday as professor of natural philosophy in the Royal Institution at London. In 1856 he joined with Prof. Huxley in investigating the glaciers of Switzerland, and the results were given in a joint paper. Tyndall returned to Switzerland in 1857 and subsequent years, and after heroic exposure succeeded

in determining the winter motion of the Mer de Glace. In 1859 he began to investigate radiant heat, which led to his famous essay, *Heat Considered as a Mode of Motion* (1863), and his lecture *On Radiation* (1865). He had already received the degree of LL. D. from the University of Cambridge in 1855 and from Edinburgh in 1866; and Oxford joined in acknowledging his eminent merit by giving him the degree of D. C. L. in 1873. In the year 1872 he made a very successful lecturing tour in the United States, treating especially of light, heat, and sound. After defraying his expenses he gave the remainder of the proceeds, amounting to \$13,000, to a committee in aid of students who devote themselves to original research. In August, 1874, Prof. Tyndall presided at the annual meeting of the British Association held in Belfast. His opening address excited a great sensation by its support of materialism. He declared that he saw "in matter the promise and potency of all the forms of life." The address was published "with additions and a preface" (1874). He had already greatly shocked the conservative religious portion of the community by proposing to test the efficacy of prayer in behalf of a portion of the patients of a hospital. He was scientific adviser to the British Board of Trade and to the light-house authorities, but he resigned these duties in May, 1883. Prof. Tyndall has a cottage on the Alps and has given much time to the various natural phenomena to be observed in those lofty regions. Several of his books have reference to mountains. Besides his publications already mentioned may be noted *Sound* (4th ed., 1883); *Fragments of Science* (5th ed., 1876); *Forms of Water* (1872); *Floating Matter of the Air* (1881).

TYNG, STEPHEN HIGGINSON (1800-1885), clergyman, was born at Newburyport, Mass., March 1, 1800. He graduated at Harvard College in 1817; after spending two years in business pursuits he studied theology. He became rector of an Episcopal church at Georgetown, D. C., in 1821, and afterwards had charge of a church in Maryland until 1829. He then removed to Philadelphia, where he was rector successively of St. Paul's and Epiphany Churches until 1845. From that year until his retirement in 1878 he was rector of St. George's Protestant Episcopal Church in New York city. He died at Irvington, on the Hudson, Sept. 4, 1885. Dr. Tyng was an eloquent preacher and ready speaker. As a leader of the Low Church party he cultivated friendly relations with all Evangelical denominations. He was editor of the *Episcopal Recorder* in Philadelphia and of the *Protestant Churchman* in New York. He was an active promoter of Sunday-schools. Many of his sermons were gathered into book form. Besides these he published *Memoir of G. T. Bedell* (1835); *Forty Years' Experience in Sunday-Schools* (1860); *The Spencers* (1870); *The Office and Duty of a Christian Pastor* (1874). Under the title, *A Child of Prayer* (1866), he published a memorial of his son, Rev. Dudley A. Tyng, who had succeeded to his father's charge in Philadelphia, but was accidentally killed.

TYPHOID FEVER. See FEVER.

TYPOGRAPHY. For a full account of the invention and early history of the art of printing, and a complete exposition of that art, together with accurate definitions and descriptions of the phraseology of the composing-room and press-room, the reader is referred to the *ENCYCLOPEDIA BRITANICA*. The work of the American printer and the tools and phraseology of his art are essentially similar to those of the English printer. Passing by these topics, this article will treat of the American printing-press, and especially of the rapid machines invented in recent years to meet the demands of the great daily newspapers. In all the successive achievements leading up to the marvellous results of the present time American inventors have held an honorable place. In

See Vol. XXIII.

p. 681 (p. 723

Am. Rep.).

1827 the English firm of Cowper & Applegarth made important improvements on the old Koenig press, and built for the *London Times* a four-cylinder press which turned off 4000 or 5000 single impressions an hour. But when, a few years later, the American inventor, Richard Hoe, of New York, developed his so-called "lightning press," capable of printing 20,000 impressions an hour, the *London Times* was among the first to tear out its Applegarth presses and purchase the Hoe machines. Wondering crowds gazed at the first of the new Hoe machines when it was set up in the press-room of the *Philadelphia Public Ledger*. A few years later similar machines were in daily use by the *New York Tribune*, *London Times*, and *Paris La Patrie*. The eight- and ten-cylinder press certainly looked like a finality, but was soon superseded by the web perfecting press, which prints both sides at once from stereotype plates that can be duplicated to any extent desired, thus making it possible to have

gradually. Its evolution has been well described in *The Paper World*:

"The use of the continuous web of paper was suggested by Sir Rowland Hill as long ago as 1835; and in 1849 Jacob Worms, of Paris, hit upon the idea of curved stereotype plates secured to a rotating cylinder. Worms even built a press in which the printed sheets were separated from the web by a serrated blade and tension rollers, as in some perfecting presses now used, and made stereotype plates from a papier maché matrix, the material still considered the best. The press was patented in England in 1850, but met with no success, partly because it failed to deliver the sheets as fast as printed, and partly because the process of stereotyping, as then understood, involved too much delay. It was not until 1861 that the latter difficulty was overcome by Charles Crask, a New York engraver, whose improved stereotyping process was at once adopted by the *New York Tribune*. This made the

Old Style Ten-Cylinder Hoe Machine.

any number of presses at work simultaneously upon the same edition and on a continuous roll or web of paper. A glance at the accompanying cut, illustrating the old cylinder press at work, and a comparison with the illustration of the modern perfecting press, will give a fair idea of the vast improvement over the old form. The new invention practically quadrupled the productive capacity, while it required less than half the labor for running the machine. It naturally became the ideal press wherever great speed was necessary. The old cylinder presses are still found in many newspaper offices, and they give good results in the publication of weeklies or even dailies of comparatively small circulation; but wherever time is reckoned by seconds instead of by hours, there the rotary perfecting press is found, reeling out its perfect eight-page papers at the rate of 700 or more every minute.

The making of this marvellous machine came about

use of duplicate forms possible. The first web perfecting press capable of doing the work of a large morning newspaper was built by William Bullock, of Pittsburg, for the *Cincinnati Times* in 1861, and soon after a similar press was tried by the *New York Tribune*. Neither of these, however, accomplished all that was expected of it, and Mr. Bullock worked at his invention several years longer before he finally surmounted all obstacles and produced the improved press capable of printing 10,000 perfect newspapers per hour. The Walter press, which prints the *New York Times* and the *London Times*, is similar to Bullock's, with the addition of several improvements in matters of detail, which give it greater speed. (For illustration see Fig. 14 in article TYPOGRAPHY in the *ENCYCLOPÆDIA BRITANNICA*.)

When these perfecting presses began to attain a speed of 8000 to 10,000 papers an hour, an unexpected limit was found in the impossibility of delivering be-

yond a certain rate from the fly. Richard Hoe and Stephen D. Tucker invented the contrivance that first obviated that difficulty in 1877—an accumulating cylinder on which six or eight sheets were laid one above another, and then delivered from the fly at one motion. This increased the practical working speed of the perfecting press to 18,000 per hour. Previous to that these gentlemen had designed a web perfecting press embodying all the improvements of Bullock, Walter, and other inventors, with many of their own. It was a lighter, more compact, and stronger machine, and rapidly superseded all others in the press-rooms of the great dailies. A folding attachment was then added, next a pasting and cutting attachment, and finally, in 1879, the most perfect printing machine up to that time made was first put into the press-room of the *St. Louis Republican*. Its production was 30,000 perfect eight-page papers per hour, printed, cut, pasted, and folded. That, like the ten-cylinder machine, seemed to be the end of printing press improvement; but the improvement has since continued.

The immense circulation attained in recent years by the great English and American dailies, together with the ever-present necessity of holding open their pages for "the latest news," has presented to the press-builder an intricate problem. The modern practice of expanding the four-page paper into the six- or eight-page sheet and the eight-page journal into one of ten or twelve pages on days when the pressure of the news or the demands of the advertiser warrant it has complicated that problem still further. The problem has been solved, however, by the invention of that marvel of mechanical ingenuity, the double supplement insetting press, by means of which a single or a double sheet supplement is readily turned out, cut, pasted, and folded into the body of the paper and that, too, at a rate of speed which permits the holding open of the news pages until the latest possible moment.

The development of journalistic enterprise has made ever-increasing demands upon the resources of mechanical ingenuity. The most rapid and the most reliable of the machines which have enabled it to do so are those of American make. They are found to-day in the press-rooms of the leading newspapers of England, Ireland, Scotland, and even in New Zealand and Australia, as well as in those of the greatest American dailies.

Probably the most productive printing-press ever built for making four- and six-page papers is that constructed in 1883 by Richard Hoe & Co., of New York and London, for a Philadelphia afternoon newspaper. It is claimed for this remarkable machine that it is capable of printing, pasting, counting, and folding ready for the carrier 96,000 four-page papers per hour, 48,000 six- or eight-page papers, or 24,000 ten-, twelve-, or sixteen-page papers, the four-, six-, and eight-page papers counted in lots of either 50 or 100, and the twelve- and sixteen-page papers in lots of 50, the papers being cut at the head, pasted, and folded half-page size. The ability to make the "inset" of an extra sheet, thereby making a six-page paper instead of one of four pages, whenever it seems desirable, is an advantage which every newspaper publisher appreciates. Aside from the loss of time involved in the process, the simple folding in of a single supplement sheet by hand, without pasting it, is often objectionable alike to the reader, the newsdealer, and the advertiser, and the extra sheet, if loose, is likely to be lost or discarded. It is such considerations as these, together with the considerable economy both of time and labor, that have placed the so-called perfecting, insetting, or double supplement machines far in advance of their foreign competitors in the race for speed and popular favor.

One of the best illustrations of the highest attainment in the art of press-building, up to the present time, is the Hoe quadruple web perfecting press which is now in daily use by the *New York World* and some

other metropolitan dailies. It prints four-page papers at a running speed of 90,000 per hour, folded carrier size; six- and eight-page papers at a speed of 45,000; and ten- and twelve-page papers at a speed of 24,000 per hour. As this machine is an excellent type of its class a somewhat detailed description of its mechanism is given.

A year was required for the building of this machine. It is composed of about 6500 parts and weighs about 53 tons. In each revolution of the plate cylinder it prints either four complete eight-page papers, or two complete sixteen-page papers with one eight-page sheet inserted in the other. In case of accident, either the main press or the supplement press can be run independently of the part which is crippled.

In the cut of the quadruple press the end of the press at the right is the supplement end, and the long cylinder near the top contains eight plates. The great roll of paper is near the floor to give steadiness to the machine and facility for handling. The paper roll of the main press, which prints the main sheet of the paper, is at the extreme left near the floor. The two presses are at right angles to each other, but are operated by the same power, and together, as in the case of the double presses, which are similarly arranged, but on a smaller scale. There is a passageway between the main and supplement presses, and the main shaft for the supplement press is shown crossing the aisle near the floor. About two-thirds of that part of the machine to the right of this aisle is taken up by the supplement press, the remaining third being the apparatus for folding all the sheets which both presses can deliver.

The great roll of paper for the main press is about 6 ft. wide, weighs 1700 pounds, and requires two men, with block and tackle, to handle. The width of the margin of the printed page is regulated by a screw controlled by a hand wheel, shown at the head of the paper-roll spindle. This head is also equipped with a safety-brake, governed in a second by the smaller lever of the two inclined to the right. This safety-brake is used only in case of emergency; as, by means of an automatic paper-feed and paper-brake combined, the press is supplied with paper at the exact speed and tension required. This is done by an endless rubber belt, the outer end of which rests upon the top of the paper roll. The large main lever has a quadrant and latch like the reverse lever of a locomotive. This starts or stops the press by shifting the main driving belt, being assisted in stopping by a powerful friction-brake pressing upon the driving pulley on the main shaft.

To the left of this starting-lever are seen the ends of two cylinder shafts. The upper cylinder carries eight stereotype pages, which are supplied with ink from an ink fountain at the highest point of the left-hand end of the machine, as it appears in the cut. The ink is distributed by composition rollers having both a revolving and shifting motion so as to distribute the ink that is fed to the distributing rollers by the adjustable fountain. By thumb screws placed closely together along the entire length of the ink fountain, the flow of ink to any portion of the rollers can be regulated to a nicety, thus enabling the pressman to put more or less "color" upon any column in the paper. The lower cylinder is the impression cylinder, carefully jacketed and so adjusted in position as to bring the paper, which travels between it and the inked plate cylinder, up against the latter, giving it a full and perfect impression.

The endless web is thus printed upon one side, and it then passes between the large second-impression cylinder (shown at the right of the starting-lever) and the second plate cylinder (shown in line with the first). This gives upon the other side of the web the impression of the opposite pages. The paper web runs along the line of the top of the frame and over the aisle and

MODERN DOUBLE SUPPLEMENT STEREOTYPE PERFORMING MACHINE.

turning-bar placed diagonally across the frame, from which it passes down into the supplement press at right angles to its former course. The operation of the supplement press (on the right in the engraving) is practically the same as that of the main press. In case of the quadruple press each division of the machine has the same producing power as regards size and number of sheets.

After the web from the main press is carried over the angle-bar, which changes its direction to one at right angles to its previous course, it passes around a roller, which returns it upon its course in the direct path with the sheet coming from the supplement press. Thereafter the double web passes to the head of the "formers," where a rotary knife separates the two sheets lengthwise of the web. Each part passes down over the "former," which is an inclined triangular form, placed point downwards between two rollers, which completes the operation of making a central lengthwise fold in the double half-web.

The folding triangle is inclined about 50° to the horizontal, and its shape is such that as the sheets glide smoothly but rapidly down its outer surface the outer edges of the web are curved down and inward until upon leaving the triangle they gradually meet between a pair of horizontal rollers. The width of the combined web is now only that of a single page, but it still continues a continuous web. A pair of folding- and cutting-cylinders carries a double set of knives, which separate each eight-page or ten-page sheet, as the case may be, from the moving web, while folding-blades on the opposite cylinders crease the paper across the middle of the page and thrust it between the small rolls, which give it the final fold and hurry it to the delivery.

Before a paper is completely separated from the web small pins dart out from the folding-cylinder close to the blade and catch the web, so as to hold it until after the length of a page has been completely severed. This is accomplished by the paper being grasped by a series of tapes running faster than its previous speed, which, breaking the points of attachment which were left by the cutting-blades, rush the papers to a collecting-cylinder. The pasting is done by the web running over the edge of a pasting-wheel, which revolves in a trough of paste, and leaves a track of paste down the centre of one of the webs.

The papers are dropped, folded half-page size, upon a set of leather belts, which carry them out from the folding-machine, and automatically count them in piles of 50 as they go. The folder can be run in connection with either one of the printing-machines or with both. This machine occupies but little space and requires only three men and two boys to operate it. The various supplement presses work almost exactly as the quadruple press does, only the size of the supplement sheet is smaller. The quadruple press might be called a double double-perfecting press. The other supplement presses from which the quadruple has developed are really triple presses.

By means of these compound presses, capable of running two webs of paper through them, it is possible, by varying the cutting up of the webs, and by using one-half of the press or both, to make two-, four-, six-, eight-, ten-, twelve-, or sixteen-page papers. These presses accomplish their work with much less liability to stoppage from choking or clogging of the printed sheets while passing through the folder than their predecessors did. The great power and production of these presses are due to their simplicity of construction. While a single machine accomplishes its work with a considerable detail of complicated mechanism, such as the switch, the collecting-cylinder, a perfect network of tapes, etc., the new double stereotype inseting machines dispense with nearly all these, except the tapes, which are reduced in number and extent.

As often as some new invention or some new application of an old one has eclipsed all former achieve-

ments, so often has an applauding public believed that the acme of perfection in the building of speedy presses has been reached; yet the ideal is still before us. It may well be that the machine just described will in time share the fate of its predecessors and give place to a greater one, but up to the present time it may be said to mark the highest attainment of the art.

COLOR-PRINTING.

Progress in the art of color-printing, though less remarkable than that in the manufacture of newspaper-presses, deserves mention. Probably the greatest recent advance in this branch of the art is that marked by a machine only lately introduced, the inventor and patentee of which is a Philadelphian. Though this new color-press has not yet come into general use, there can be little doubt that it has proved the possibility of printing by means of a perfecting-press one sheet of paper on both sides and in several colors simultaneously, thus enabling the printer to produce an illustrated paper, book, or pamphlet in illuminated colors. Incredible as this may seem, it is claimed that the complete set-off system contrived in this machine will enable a skilled printer to accomplish this result. A recent issue of *Paper and Press* contains the following description of this interesting and important invention:

"Colors are now known to some ink-manufacturers that will work on each other while wet and give good results. This has been a constant study of the inventor for over seventeen years, and he is said to have proved that many designs may be effectively printed at one operation or passage of a sheet through a machine, thus expediting work, and often with greater advantages than handling the sheet each time separately for each color.

"Another form of this machine will enable one to print cartoons or pictures from zincographic surfaces in outline, and then fill in the picture with rich, transparent colors from relief-plates, thereby dispensing largely with very troublesome wetting of the color parts of the picture. Thus it may be converted into a semi-lithographic machine, and produce chromo-zincotypes, for illustrations suitable for a children's pictorial or serial. The style may be also adapted to print both sides at one time, where a large edition would demand it.

"The machines can be constructed to do a great range of work—from printing a series of labels in colors to printing a plain surface on one side; or the same press can be used to print a book with great rapidity on both sides at once.

"This system is based on the principle of two cylinders of unyielding construction running in harmony with each other. The plate-cylinder is twice the diameter of the impression-cylinder, and thus three points are gained; the smallest possible line of contact in impression, giving strength and speed; the largest diameter, so that the plates will not need much curvature; and a portion of the plate-cylinder to act as a table or distribution-surface for the ink. Each color or side is isolated from the other, thereby preventing a discoloration by the ink flying while in rapid distribution.

"Every color has a separate pair of cylinders. The sheet is carried rapidly between each pair of cylinders by an elastic gear-wheel, or positive-motion metallic band, to which is attached a series of grippers, and is held fast in proper position until it has received any number of impressions on one or both sides. When the sheet is perfected it is then carried by the same grippers to a point of delivery, and may be delivered on a table or passed through any ordinary folding-machine. Thus, it would be printed, if necessary, on both sides in colors, and folded ready for delivery. The speed of a machine may be made to suit any special want, because there are no reciprocating- or eccentric-motions to give impressions. All the parts

are rotary, and there are no difficult mechanical problems to be overcome."

TYPE-CLASSIFICATION.

American Point System.—English printers still suffer from the same trouble that proved a serious annoyance in this country previous to the universal adoption by American type-founders of a uniform gauge of type measurement known as the "American Point System." Type made by different founders varied considerably in the size of its body, though designated by the same name. Printers upon reinforcing an old font of minion, for instance, with a new outfit of minion made by a different founder, sometimes discovered that the difference in size between the two fonts was so considerable that the type would not "justify," and consequently the two fonts could not be mingled. This difficulty has been obviated by the adoption of the "Point System." This system lays down the cardinal dictum that the dimension of pica body shall be 12 "points," and that 83 pica bodies—996 points—must be exactly equivalent to 35 centimetres. Here we have a unit of measurement (the point) which is based upon the French metric system—an invariable gauge. Having agreed upon this sound basis the American type-founders adopted the following uniform measurements for the bodies of type in common use:

Name under Point System.	Name under Old System.
3-point body	<i>Excelsior.</i>
3½ " "	Brilliant.
4 " "	<i>Semi-Brevier</i>
4½ " "	Diamond.
5 " "	Pearl.
5½ " "	Agate.
6 " "	<i>Nonpareil.</i>
7 " "	Minion.
8 " "	<i>Brevier.</i>
9 " "	Bourgeois.
10 " "	<i>3-line Excelsior.</i>
11 " "	Long Primer.
12 " "	Small Pica.
14 " "	<i>Pica.</i>
16 " "	2-line Minion.
18 " "	English.
20 " "	2-line <i>Brevier.</i>
22 " "	Great Primer.
24 " "	<i>3-line Nonpareil.</i>
26 " "	2-line Long Primer.
28 " "	Paragon.
30 " "	2 line Small Pica.
32 " "	2-line <i>Pica.</i>
34 " "	2-line English.
36 " "	5-line <i>Nonpareil.</i>
38 " "	3-line Small Pica.
40 " "	4-line <i>Brevier.</i>
42 " "	2-line Great Primer.
44 " "	3-line <i>Pica.</i>
46 " "	Double Paragon.
48 " "	7-line <i>Nonpareil.</i>
50 " "	4-line Small Pica.
52 " "	Canon.
54 " "	4-line <i>Pica.</i>
56 " "	5-line Small Pica.
58 " "	9-line <i>Nonpareil.</i>
60 " "	5-line <i>Pica.</i>
62 " "	6-line <i>Pica.</i>

Height to paper, 2½ centimeters.

The bodies indicated in italics in the above table are those whose dimensions, as made by the most extensive American type-founders prior to the adoption of the new system, were the same as they now are under the point system. The old excelsior, brevier, or pica, for instance, as made by the best founders before the innovation, is identical with that now adopted, and mixed fonts of the new and old would justify readily. But the new brilliant, diamond, or pearl would not work with the old bodies, each being a fraction of a point larger or smaller than was the prevailing brilliant, diamond, or pearl of the old régime.

The pica body adopted as the standard under the point system was that made by the Johnson type-foundry, of Philadelphia, the oldest of its kind in the country, being established in 1794.

MUSIC-TYPOGRAPHY.

Music-typography is the art of representing a musical composition by the combination of movable types, on which are the staff-lines and the various musical signs and characters. The art, though an old one, has only recently been developed to a high state of perfection. As early as 1482 Oct. Scotus, of Venice, printed music from type at two separate impressions, the first printing the staff only and the second the notes upon it. Erhard Oeglin, of Augsburg, in 1507 was the first to succeed in printing both the staff-lines and the music at a single impression. He may be regarded, therefore, as the pioneer of the present system, though his productions were naturally crude as compared with the work of the present time. The early form of printed notes was square: then a diamond- or lozenge-shaped note-head was substituted, and in the latter part of the seventeenth century the round-shaped note now in common use was adopted. The first American who employed movable type for the printing of music was Christopher Sower, of Germantown, Pa., who, in 1753, printed and published in the German language a *New, Enlarged, and Complete Song-Book, wherein are contained as well the Psalms of David.* Sower cast his own type, and his musical typography was legible, but still crude and far from beautiful. As the art of stereotyping did not come into general use until about the year 1810, all music-printing prior to that time was done directly from the type. The wear and tear of press-work soon battered the type so seriously as to impair or ruin it, and the process of musical typography was an expensive one. At present, however, the type itself is used only as the basis from which are cast, either electrotypes or stereotype plates. The printing is done from these plates, and the type, not coming in contact with the press at all, with careful usage on the part of the compositor and electrotyper, may be made to serve for a long time without injury.

John M. Armstrong, who was born in New York, in 1833, and died Jan. 25, 1878, probably did more than any other American to develop the art of music-typography to its present state of perfection. He made this task the study of a lifetime, and in many ways improved greatly upon the German fonts, which up to his time had been the best available. To his efforts was due the introduction of many new logotypes, brass lines, stems, and straight ties of various lengths, all of which are recognized as among the indispensable features of the present system.

A page of music-typography is made up of an indefinite number of small pieces, so united by the deft hands of the compositor as to represent continuous lines and characters. If the type is in good condition and the work is done skilfully there are no breaks visible between these many small component parts, the junctures being so perfect as to defy detection. For instance, the group of notes combined in Fig. 1 is made up of 29 pieces, as shown in Fig. 2. To make the

Fig. 1.

Fig. 2.

various and almost infinite combinations required in the representation of an intricate piece of music upwards of 500 separate typographical characters are used by the musical-compositor. Figs. 3, 4, and 5 represent the upper-, lower-, and side-cases, comprising a full font of music-type, with each character located in the box or compartment in which it belongs. In the upper-case are shown in the left-hand side the ties used for connecting the stems of the notes. These are

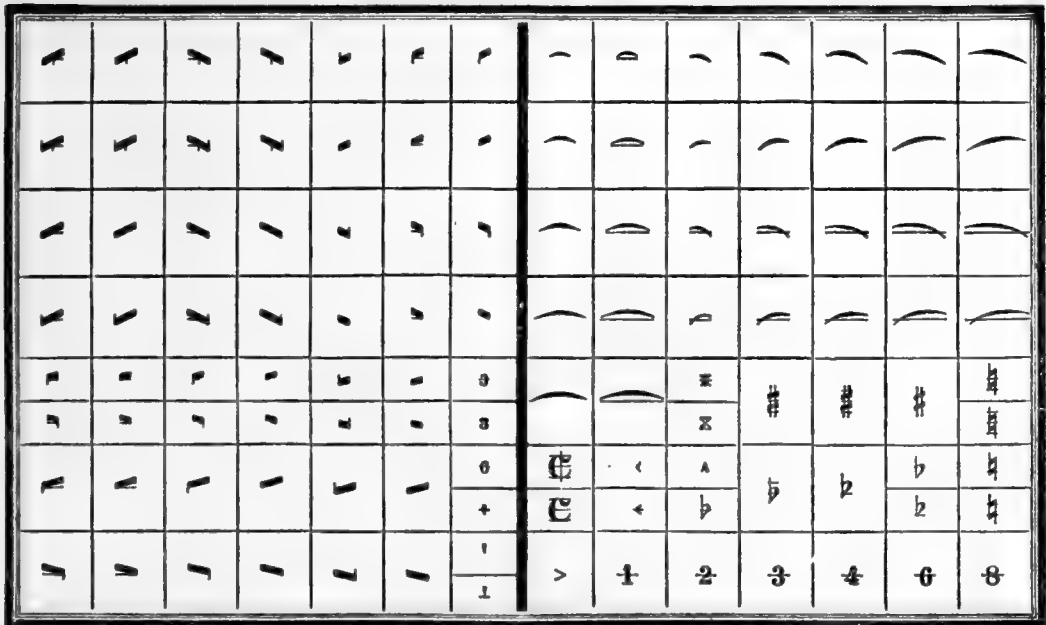

Fig. 3.

necessarily of various lengths, and produced at various angles to the staff-lines, in order to connect properly notes or different portions of the musical staff; in the right-hand section of the case is a similar assortment of slurs, also adjusted at varying angles to the staff-lines, for the same reason; there, too, are the accidentals (sharps, flats, etc.), some of them on the staff-lines and others on the spaces.

In the lower-case (Fig. 4) are the several notes and rests—some on the lines and others on the spaces—note-stems, bass and treble-clefs, pauses, the quadrates, and sections of the staff-lines in various lengths.

In the middle compartment of the side case (Fig. 5) are the characters known to the musician as grace-notes, the diminutive accidentals, etc., and the other sections of the same case contain the numerals, crescendo and diminuendo characters, and other symbols which the musician will recognize readily.

There are in common use five styles of music type, the "bodies" of which are of different sizes. There are also various fonts of the same sized "body," but printing the note-heads larger or smaller. The prevailing styles are shown in Fig. 6. The smallest type, beginning at the top of the figure, is known as "Excelsior 2," and the others, in the order in which they are shown in the plate, are "Excelsior Music," "Diamond," "Diamond 3," "Diamond 2," "Agate 3," and "Nonpareil 3."

Character Note Systems.—Various typographical devices have been introduced from time to time with the common object of simplifying the reading of musical compositions. None of these has as yet been adopted so extensively as to supersede the common system, though the device known as the Tonic Sol-Fa system is meeting with considerable favor, especially in England. The Tonic Sol-Fa system dispenses en-

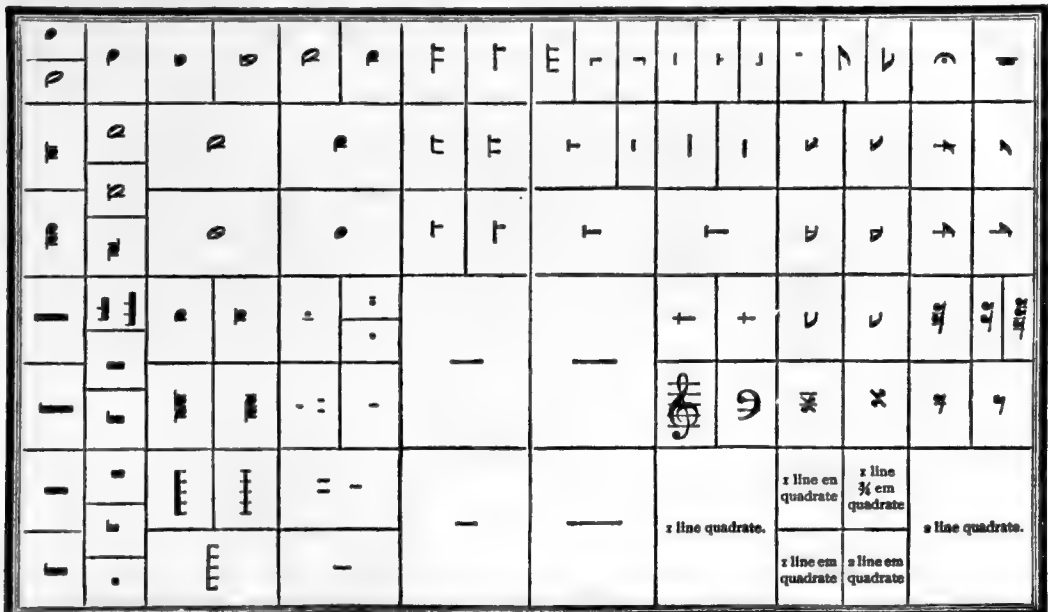

Fig. 4.

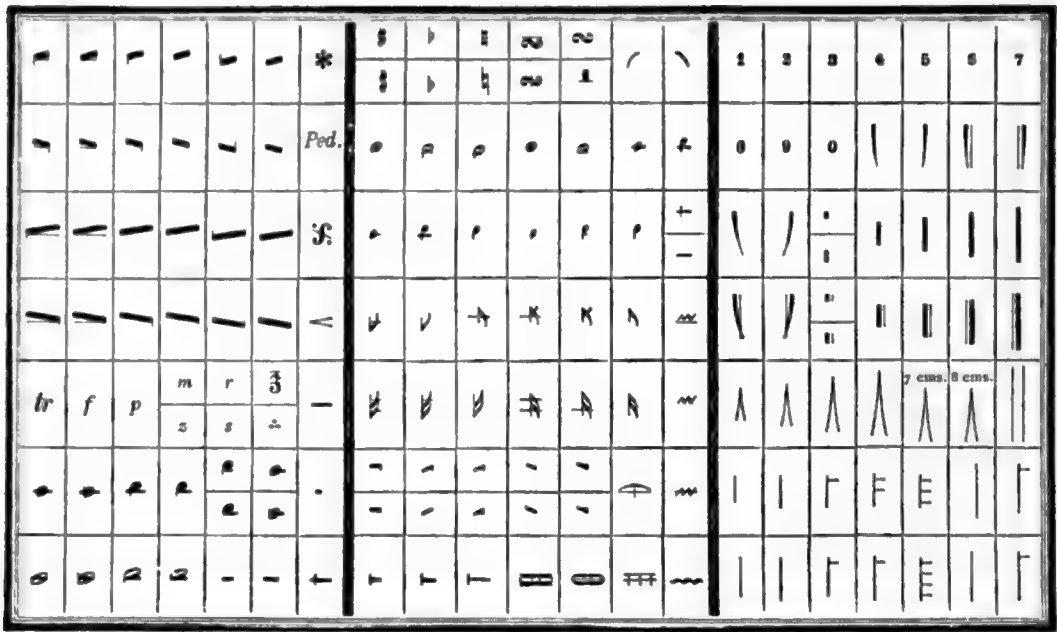

Fig. 5.

tirely with the common staff-lines of the musical scale, and also with the note characters. The seven tones (*do re mi fa sol la si*) are indicated by the initial letters, *d, r, m, f, s, l, and t*, printed in bold, plain-faced type. An upper tone is distinguished from the one an octave below it by means of an accent mark printed above the initial letter which indicates the note. By combinations of these initial letters any musical chord may be represented readily enough, while the time, the value of the several notes, the rests, pauses, slurs, etc., are represented by similar typographical expedients, which are not difficult to master.

Another idea which has been developed in various forms is that of indicating the tone by the peculiar shape of the note-head, the theory being that the shape of the note-head, together with its distinctive position on the staff, makes a double appeal to the eye of the musician and renders the note more readily identified. One of the most ingenious of these systems is that introduced by Jesse B. Aikin, an American, who contrived a different shaped note-head for each of the seven tones, round, semi-circular, rectangular, diamond-shaped, and triangular forms, all being employed in his method. In all of these devices the shape of the note-head is the main distinguishing feature, the staff lines still being retained generally (though the idea theoretically permits of their abandonment), and the values of the several notes being represented by note-stems, dots, etc., as in the prevailing system.

In Aikin's system the seven characters employed are as follows:

do re mi fa sol la si

The smallest type, beginning at the top of the figure, is known as "Excelsior 2," and the others, in the order in which they are shown in the plate, are "Excelsior Music," "Diamond 3," "Diamond 2," "Agate 3," and "Nonpareil 3."

U.

UMBRELLA TREE. The tree known under this title is one of the several American species of magnolias, its specific designation being *magnolia umbrellata*. It is a small tree, rarely more than 36 ft. high, and with a trunk less than a foot in diameter. Its range is from south-east Pennsylvania along the Alleghenies to central Alabama, and westward through Kentucky and Tennessee to north-east Mississippi, it also oc-

Umbrella Tree.

curing in central and south-west Arkansas. It is most common on the western slopes of the southern Alleghenies, where it frequents rich, shady hillsides. Like all the magnolias it is a handsome tree, bearing very large, white, highly-scented flowers, and a rose-colored fruit. It gets its name from the fact of the leaves being crowded on the summit of the flowering branch in an umbrella-like circle.

UNION COLLEGE. This institution of learning at Schenectady, N. Y., was founded in 1795 by the Regents of the University of the State of New York, in response to a petition of 127 citizens of the State. Several earlier but unsuccessful efforts had been made to accomplish the same end.

The prime movers in all later efforts were the proprietors of the Schenectady Academy, originally established in 1785 under the patronage of the Reformed Dutch Church. In 1792 and again in 1794 the request of its managers for a charter under the title "The College of Schenectady," was denied, but finally a plan was framed designed to obviate the objections made to former applications, and coupled with an offer of the immediate use of the academy building. This scheme proposed the name "Union College" and provided guarantees for the independence of the institution from all sectarian bias. The charter was granted on Feb. 25, 1795, over the signatures of George Clinton, governor and chancellor, and De Witt Clinton, secretary. The charter granted all the rights and privileges enjoyed by Columbia College, fixed the number of trustees as twenty-four, gave them power of perpetual succession, of appointing officers of instruction and government, of making ordinances for government, and of conferring such degrees "as are usually granted by any or either of the universities of England." Subsequent amendments reduced the number of trustees to twenty-one, and admitted certain officers of the State to *ex-officio* membership. In 1873, by act of the Legislature, an additional university charter was obtained by which permission was granted several existing institutions to unite with Union College in the formation of Union University.

The new institution was housed at once in the two-story brick academy building, 50 by 30 feet, and remained in these humble quarters until a new and commodious structure of stone, three stories and basement, 150 by 60 feet, costing about \$56,000, was completed in 1804. Since 1854 this building has

been the main edifice of the public school system of the city. The only evidence of its former collegiate use remains in the name of the neighboring "College street."

During the first nine years of its history, 1795 to 1804, the college had three presidents, Rev. John Blair Smith, D. D., Presbyterian, Rev. Jonathan Edwards, D. D., Presbyterian, and Rev. Jonathan Maxcy, D. D., Baptist. In 1804 began the presidency of the distinguished Eliphalet Nott, D. D., LL. D. At the time of his election to the presidency he was a Presbyterian clergyman in the city of Albany, a member of the board of trustees of Union College, and known to the general public chiefly as the author of the funeral oration over Alexander Hamilton. Dr. Nott retired from the official management of the college in 1861, after nearly sixty years of continuous service, but he really continued to direct the affairs of the institution until his death in 1866. He was succeeded by the profound metaphysician, Rev. Laurens P. Hickok, D. D., LL. D. Upon the retirement of Dr. Hickok in 1868, the nominal presidency was conferred upon the Hon. Ira Harris, LL. D., of Albany, then president of the board of trustees. The actual management of the college, however, devolved upon Prof. Isaac W. Jackson, LL. D., senior member of the faculty. Subsequent presidents were Rev. Charles A. Aiken, D. D., Ph. D., a graduate of Dartmouth, and Rev. Eliphalet Nott Potter, D. D., LL. D., a grandson of Dr. Nott and an alumnus of Union, who succeeded Dr. Aiken in 1871. During the administration of Dr. Potter, 1871 to 1884, the buildings were materially improved, their number increased, the classes enlarged, and the funds of the college strengthened. Upon the retirement of Dr. Potter in 1884 to take the presidency of Hobart College occurred an interregnum of four years, during which affairs were directed by Hon. Judson S. Landon, LL. D., as president *ad interim*.

In June, 1888, Harrison Edwin Webster, LL. D., an alumnus and former professor of the college, was called to the vacant presidency. Among eminent instructors connected with the college at various times during its history may be mentioned Rt. Rev. Alonzo Potter, D. D., LL. D., who subsequently became Bishop of Pennsylvania; Rev. Francis Wayland, D. D., LL. D., subsequently President of Brown University; Tayler Lewis, LL. D., the eminent oriental scholar and author, one of the foremost Greek scholars in the United States; William Mitchell Gillespie, LL. D., founder of the school of civil engineering at Union; Isaac W. Jackson, LL. D., author of various mathematical works; Jonathan Pearson, A. M., distinguished for antiquarian researches, and John Foster, LL. D.

The grounds of Union College comprise about 130 acres, within city limits but on the north-east verge. They are greatly diversified, and command a wide and charming view. They include also a famous garden of several acres, the memorial of Dr. Jackson, whose name it bears and to whose devotion its loveliness is a perpetual witness. The present buildings occupy a broad level terrace nearly half a mile in length. The main structures, North and South Colleges, respectively, are each in the shape of an L, and include between their long arms a campus 600 feet in breadth. The front line of buildings, 200 feet long in each college, is four stories in height, and is flanked by the residence of a professor, one at each extremity and one at each angle, making four in all. The wings, somewhat lower, and called the colonnades, extend at right angles 300 feet to the rear and include the campus between their parallel

sides. The material is brick, grouted gray, and diversified by pilasters of white. The front edifice of each college is subdivided into three sections, each containing 16 rooms and giving a total dormitory accommodation of about 200. The engineering-rooms, the chemical and physical laboratories, the armory, the natural history museum, the chapel, and the recitation-rooms of the departments of Greek, modern languages, engineering, chemistry, physics, natural history, and military science are contained in this set of buildings.

At the back of the campus, midway between the colleges, stands a sixteen-sided structure of stone, 84 feet in diameter, and surmounted by a dome rising to a height of 120 feet above the ground-floor. The exterior ornamentation is white sand-stone and Scotch granite. The interior has a mosaic pavement of Salop tile, the walls are rivetted with polished marble, the galleries are of corrugated iron, and light is admitted through stained glass. This costly structure was erected by Dr. Potter at the cost chiefly of the Hon. Clarkson N. Potter, and Mr. Howard Potter, as a memorial of Dr. Nott. At a short distance to the rear is a semi-circular structure of pressed brick. The central part, two stories in height, and fire-proof, contains the library.

The wings hold the recitation-rooms of the departments of mathematics, English, Latin, philosophy, and ethics. The central portion is styled "The Washburne Memorial Library Hall," the rest of the structure "The Thomas Henry Powers Memorial Hall." The gymnasium is a detached structure of brick in the rear of South College. In addition to the four residences already mentioned are the following: the dwelling, formerly Dr. Nott's, now occupied by the president; the house built by Dr. Potter for his use; a handsome Swiss cottage erected by Hon. Samuel T. Benedict for the use of Dr. Jackson and wife, and in virtue of this consideration held by himself under a life-lease, and two other residences. The remaining buildings are the photographic rooms, bath-houses, stables, and cottages occupied by college servants.

The departments of law, medicine, pharmacy, and the observatory which with the college constitute the university are situated in Albany.

The library contains about 30,000 volumes. Its special features are the Gillespie collection of engineering and scientific works, the Patterson collection of mathematical works, and very complete sets of the great literary reviews. Connected with it is a reading-room supplied with the leading current magazines and reviews.

Under the title of apparatus and collections may be mentioned the following: 1. In physics a costly set of apparatus for illustration and experiment in electricity, magnetism, light, heat, acoustics, pneumatics, etc. 2. In natural history, the Wheatley collection of shells and minerals, the gift of the Hon. E. C. Delavan, valued at over \$80,000. The collection of marine invertebrate faunas, made by President Webster and his assistants during his incumbency of the professorship of natural history, representing the results of fifteen years of special research along the Atlantic coast of North America and the west shore of the Gulf of Mexico, and of exchange of duplicates for specimens from nearly every part of the world. The fine collection of North American birds, gathered and mounted by James E. Benedict, A. M., some time assistant to the department of natural history. 3. In engineering, instruments of every class, representing the entire development of practical engineering. The Olivier models, 50 in number, representing the most important and complicated surfaces of descriptive geometry, invented by Prof. Theodore Olivier, of the Paris "Conservatoire des Arts et Metiers." Of the three existing sets, Union College has the fullest and the original. Bardi's (Paris) plaster models of intersections, Schroeder's (Darmstadt) models, stone-cutting

models from "L'École Polytechnique," architectural models from "L'École des Beaux Arts," bridge models, including Doyne's dynamometer bridge model, etc., and over 50,000 plates of engineering and architectural structures.

The courses of study offered at Union are four: the classical, the scientific, the Latin scientific, and the engineering. The degrees conferred in the course are A. B., B. S., and C. E. The faculty includes the president, eleven professors, a professor emeritus, a tutor, and a lecturer. There are several grades of scholarships, granting credits that range from \$50 to \$300 per year. Various commencement prizes are offered for excellency in oratory, essays, debate, and general standing.

The list of commencement prizes embraces:

Oratory,	{ Blatchford Medals,	two.	Total value \$70.
	{ Junior and Sophomore,	four.	" " 50.
Extemporaneous	{ Veeder,	one.	" " 70.
Debate,	{ Ingham,	one.	" " 50.
	{ Clarke,	two.	" " 25.
Essays,	{ Allen,	three.	" " 60.
Conduct	{ Warner Cup,	one.	" " 50.
and	{		
Standing,	{ Military,	three.	" " 75.

Honors consist of assignment to place among the ten commencement orators, the valedictory, special mention for high standing and extra work.

College Societies.—The old Adelphic and Philomathean Debating Societies still exist, but their function has in large measure been transferred to the secret societies. The students publish the *Concordensis* monthly during college year, and the *Garnet* annually.

(J. R. T.)

UNITED LABOR PARTY is a political organization which grew out of the Central Labor Union in New York city. This union was established in the winter of 1881-82, and its origin is traced to a meeting held for the purpose of expressing the sympathy of workmen in New York city with the poor of Ireland. In the autumn of 1882 the Union nominated candidates for Congress, the State Assembly, and the city board of aldermen. But the Labor vote in the election was trifling until Henry George (q. v.) had commenced an agitation for the nationalization of land. In July, 1886, the Union appointed a committee to prepare a plan of political action. After several conferences a city convention was held Sept. 23, at which 176 labor organizations were represented. The platform adopted practically affirmed George's doctrines, and the convention nominated him for mayor with little opposition. The candidate of the united Democracy was Abram S. Hewitt, and the Republican candidate, Theodore Roosevelt. Mr. George made over 100 speeches during the campaign, and by his energetic action roused both friends and foes to unwonted efforts. Before the nomination he had received the pledges of 34,000 voters. The election gave Hewitt 90,552; George, 68,110; and Roosevelt, 60,435. As the strength of the Greenback-Labor party (see GREENBACK PARTY) had been in the country districts, this result seemed to show that a similar element existed in the large cities. The problem for their leaders was how to unite these elements in an effective organization. In New Haven the Labor party obtained about 1000 votes in November, 1886, but the movement in Boston failed as an element in the campaign. In New York city those who supported George determined to call themselves the "United Labor Party," and they prepared a constitution with the following preamble: "We, the representatives of the United Labor party of the city and county of New York, believing that governmental corruptions and injustices spring from neglect of the self-evident truth that all men are created equal; that the advantages arising from social

growth and improvement belong of right to the society at large, and that the true purpose of government is the maintenance of that sacred right of property which secures to every man the fruits of his own labor; demand that in the drawing of grand-jurors there shall be no distinction of class; that the property qualification for trial jurors shall be abolished; that equal pay for equal work should in public employment be accorded without distinction of sex; that police interference with peaceful assemblages should cease; that our elective methods should be reformed; that the people of New York should have full control of their own local affairs; that the procedure of our courts should be simplified; that the laws for the safety and sanitary inspection of buildings should be enforced; that all laws which bear unjustly on labor should be abolished; that in public work all labor should be directly employed; that all taxes on buildings and improvements should be abolished; that all taxes should be levied on land values which arise from and are due solely to increase of population; that existing means of transit should no longer be left in the hands of corporations, but should by lawful process be assumed by the city and operated for the public benefit."

In Chicago a branch of the party was established which required each member to take a pledge to support its candidates.

The first regular convention of the United Labor party met in New York in January, 1887. In the New York Legislature of 1887 a law was passed, with little opposition, allowing this new-born party to have two inspectors at every polling-place in the city of New York, thus giving it the same privileges enjoyed by the older political parties. It had also the advantage of an organization well provided with workers who had become alienated from the larger Democratic organizations.

Yet from this climax of its political power the United Labor party rapidly dwindled in numbers. One of the chief supporters of George was Dr. Edward McGlynn, who was suspended from his functions as a Roman Catholic priest on account of his pronounced opinions in favor of the land-nationalization theories. Many of the sympathizers with the movement could not follow it as long as Dr. McGlynn was under a ban. At its State Convention, held in Syracuse in August, 1887, Socialists were excluded from the party. Henry George was nominated for Secretary of State, and along with him a complete ticket for State officers. The platform took more advanced ground in regard to George's theories, and also resolved in favor of many measures of particular importance to laboring men, as to the hours of work, free schools, etc. In the election of November, 1887, George secured 70,055 votes in the State of New York, his vote in New York city having fallen to 37,477; but in Kings co. (Brooklyn) he had 15,635, or nearly 1000 more than his party obtained in 1886. In October, 1888, the party nominated Mr. James J. Coogan for mayor of New York city, but in the bewildering whirl of the national Presidential election he obtained only 9809 votes. Thus within two years the United Labor party dropped from the surprising vote of 68,000 to comparative insignificance. The indications are that the party has no real bond of coherence, and cannot maintain its existence as a factor in politics. But its sudden rise and its fall no less sudden form a peculiar chapter in the history of American politics. (See SOCIALISM.) (F. G. M.)

UNITED PRESBYTERIAN CHURCH OF NORTH AMERICA. This church was formed in May, 1858, by the union of the Associate Presbyterian Church and the Associate Reformed Presbyterian Church (see these titles). The basis of union was the Westminster Confession of Faith (with a slight modification) and Catechisms, and a Testimony, containing 18 articles or declarations of doctrine. Those having direct practical bearing, pronounced slaveholding a sin, disapproved secret societies, forbade the extending of

communion in sealing ordinances to persons who refuse adherence to the church's profession, and declared that in singing God's praise the Bible Psalms should be employed to the exclusion of uninspired human compositions. These declarations, practically held in common with the Reformed Presbyterian Churches (*q. v.*), yet serve to separate this body from the main Presbyterian Church. It may further be remarked that though this denomination can historically claim community of origin with the United Presbyterian Church of Scotland, it is in regard to Calvinistic orthodoxy at the furthest remove from that body.

The first General Assembly of the newly formed denomination met in Xenia, Ohio, in May, 1859. Its statistics show that it had 42 Presbyteries, 408 ministers, 634 congregations, and 55,547 members. The three synods of the Associate Reformed Presbyterian Church, namely, that of New York and the First and Second Synods of the West, formed a framework for grouping the Presbyteries. The General Assembly appointed the following boards to conduct the beneficent operations of the church: The Board of Foreign Missions, located at Philadelphia; Board of Home Missions, at Xenia, O.; Board of Publication, at Pittsburg; Board of Church Extension, at Allegheny, Pa.; Board of Education, at Monmouth, Ill. To these was added in 1863 a Board of Freedmen's Missions, at Allegheny, Pa.; and in 1873 a Board of Ministerial Relief, at Philadelphia; the latter being an expansion of an Aged Ministers' Fund, commenced in 1862.

The progress of the church has been steady. Its numbers have been increased by emigration from the north of Ireland as well as by accessions from those born in America. Its stronghold has been in Western Pennsylvania, but it has spread throughout the West, and has some churches on the Pacific coast. In 1865 Rev. W. C. McCune, of Cincinnati, then a minister of this church, published a book on *Close Communion*, advocating a wider extension of church privileges than the denominational *Testimony* allowed. He was tried by his synod and acquitted of teaching serious error, but appeal being taken to the General Assembly in 1867, that court found him guilty of maintaining serious error in regard to church fellowship. Mr. McCune withdrew to the Presbyterian Church, and afterwards passed to the Congregationalists.

The movement which had commenced in the various Presbyterian Churches of Scotch origin for the improvement of the Psalmody was continued in the United Presbyterian Church and resulted in the adoption by the Assembly of 1871 of a better metrical version of the Psalms. This newly authorized version has in a great degree superseded the Scotch version of the Psalms, often called Rous's version. In connection with the new version commendable efforts have been made to improve the singing in the churches. To this end the Board of Publication has prepared various editions of the Psalter with appropriate music. This movement led also to a discussion of the right to use instrumental music in the worship of God. The *Directory of Worship* which had been adopted by the action of the General Assembly and the Presbyteries in 1867 forbade such use on the ground that the Scriptures did not warrant it in the New Testament Church. But an increasing party grew restive under this restriction and an open controversy arose on the publication by Rev. D. F. Bonner of a pamphlet, *Instrumental Music Divinely Authorized* (1877). Several pamphlets were issued in reply to this. A vigorous movement for the repeal of the section forbidding instrumental music was begun and the question was submitted by the General Assembly to the vote of the Presbyteries. The vote as reported to the Assembly in 1881 was doubtful, but the Assembly declared the section repealed. This action was stoutly disputed, but each successive Assembly refused to reopen the question, giving various explanations of the position taken.

The advocates of instrumental music have in many cases introduced organs into their churches, and attempts to subject them to church discipline therefor have failed. Some congregations have been divided and the general work of the church has suffered, yet the annual reports to the Assembly continued to show advance in all departments.

In the midst of this controversy came in 1883 the twenty-fifth anniversary of the denominational organization. A special and vigorous effort was made to celebrate this quarter-centennial by liberal contributions to the beneficent work of the church. The net amount raised was \$369,668.86, which was distributed to the Mission Boards of the church, to its theological seminaries, to the denominational colleges, and to some local objects.

The United Presbyterian Church has been actively engaged in foreign mission work since its formation. From the churches which combined in 1858 it received under its care missions in Egypt, India, and Syria. In 1859 it started a new mission to China, but after several years of labor in that field the General Assembly decided to leave it to other denominations and the missionary was recalled to labor among the Chinese in California. The mission in Syria was likewise transferred to the Irish Presbyterian Church, which had already been associated in the work. The United Presbyterian Church has concentrated its efforts in Egypt and India (the Punjab), and its success has challenged the attention of all visitors to those countries. In both there are theological training-schools for the natives, and several churches have native pastors.

In Egypt there are 85 mission stations, 11 ordained missionaries, 10 female missionaries, 10 native pastors, 2307 communicants, and 5601 pupils, the mission property being valued at \$207,810. In India there are 69 stations, 8 ordained missionaries, 11 female missionaries, 12 native pastors, 4571 communicants, and 4341 pupils, the mission property being valued at \$29,922.

The statistics of the United Presbyterian Church for 1888 show 10 synods, 61 presbyteries, 753 ministers, of whom 507 are pastors, 57 licentiates, 42 students of theology, 3580 ruling elders, 907 congregations, of which 614 have pastors, 150 mission stations, 159 parsonages, 98,992 communicant members, 953 Sabbath-schools, with 9815 officers and teachers, and 86,450 scholars. The total contributions for the year ending April 30, 1888, were \$1,019,937, of which \$783,120 were for congregational purposes.

The church has two theological seminaries. That of the conservative wing is at Xenia, Ohio, and is the successor of the oldest seminary in the United States (see THEOLOGICAL SEMINARIES). The other, more flourishing, is at Allegheny City, Pa. Westminster College, New Wilmington, Pa., and Monmouth College, Monmouth, Ill., are denominational colleges of many years' standing and established reputation. Lincoln College, Mo., and Cooper Memorial College, Kansas, are of recent origin, and are still struggling for existence. Muskingum College and Franklin College, older institutions in Ohio, are largely patronized by United Presbyterians. At Knoxville, Tenn., is a college for the Freedmen, conducted by United Presbyterians.

Besides Sabbath-school papers and other periodicals issued by the Board of Publication at Pittsburg there are published in the interest of this church two weekly papers, *The Christian Instructor*, at Philadelphia, and *The United Presbyterian*, at Pittsburg, and also a monthly, *The Evangelical Repository*, at Pittsburg.

See Rev. Dr. J. B. Scouller's full and accurate *Manual of the United Presbyterian Church* (2d ed., 1887), and Rev. Dr. W. J. Reid's *United Presbyterianism* (1886). (J. P. L.)

UNIVERSALISM is commonly thought to mean

belief in the final salvation of all men. The system of faith which passes under this name cannot be characterized in this way. The result here predicated is but a corollary or inference from a theological conception which regards God as a moral being working by moral methods for the accomplishment of moral ends. The principles of his nature are declared to be universal in their application and issue.

History.—This view is not modern. The apostles taught that God is love and that love sent the Saviour into the world. Their successors held to this conception and stated it with positiveness. Great leaders of the Greek Church, like Clement of Alexandria and Origen, maintained by specific arguments that love must triumph in the ultimate recovery of every soul. This view prevailed until the sceptre of authority passed from the Eastern to the Western branch of the church. Then a purely legal conception of the divine nature and government, of sin and penalty, and of redemption was substituted for the moral. Augustinianism came to prevail almost exclusively until the rise of Protestantism. The latter movement produced the modifications known as Lutheranism and Calvinism. The Reformed theology of England was for the most part that taught by Calvin. The Westminster divines sought to put Calvinism into a popular form. This was the theology which the early settlers brought to this country. The whole English-speaking race at the beginning of the eighteenth century gave almost unqualified assent to it.

But very early in the century there began to be marked symptoms of dissent. Arminianism in England, and, later on, the Arminian and Socinian tendencies in America, were the signs of a protest in the bosom of Protestantism against Calvinistic predestination and election. During this upheaval the modern Universalist movement had its birth. It began on the other side of the water, but was soon transferred to America. Dr. Eddy, in his work entitled *Universalism in America*, mentions five distinct channels by which the doctrine was brought hither: 1. Dr. George De Beneville, one of the French refugees in London, 1703, after expulsion from England because of his heretical opinions, and after barely escaping death from the same cause in France, came to America in 1741, and settled in Pennsylvania, where he practised medicine and preached in different parts of the State until his death, in 1793. 2. The German Baptists, commonly called Dunkers (*q. v.*), who settled in Pennsylvania in 1719, were from the first believers in the universal restoration. 3. The Rev. Richard Clarke, rector of St. Philip's Church, having a European reputation, was pronounced in his advocacy of the doctrine. He had strong sympathizers among leading men of his denomination in different parts of the country. 4. Among the Congregationalists, the attitude of Dr. Charles Chauncey, pastor of the First Church of Boston, and of Dr. Jonathan Mayhew, of the West Church, is well known. 5. But the Universalist denomination of to-day traces its origin to the Rev. John Murray (1741–1815), who came from England to this country and preached his first sermon in Thomas Potter's church, at Good Luck, N. J., Sept. 30, 1770. Murray at twelve years of age had come under the influence of John Wesley, who honored him with his confidence, so that he became, a few years later, an advocate in his connection. But upon hearing Whitfield he adopted Calvinistic views, and became a communicant in his Tabernacle. Here he was so marked by his zeal and ability that he was specially commissioned to reclaim a young lady of the congregation who had adopted the views of James Rely, a Universalist preacher of London. The young lady was strong in her convictions, and by questions and answers raised problems in his mind which troubled him sorely. Next he began to read Rely's *Union*, a small theological treatise, and became a regular attendant upon his preaching. Completely converted to what was then

known as "Rellyism," he was then urged to become a preacher of the new faith, but declined. After the death of his wife he emigrated, hoping that he might bury himself in the wilderness. But after resisting by every means the solicitations of Mr. Potter, he consented to preach in the house which the latter had built in the confident expectation of a preacher whose views corresponded with his own. Murray at first thought he would spend his days as a kind of private chaplain to his new-found friend and his immediate neighbors. But people flocked to hear him from miles around. He says: "Solicitations, earnest solicitations, poured in from the Jerseys, from Philadelphia and from New York; and it became impossible to withstand their repeated and imposing energy." He entered upon a series of missionary journeys which carried him as far north as Portsmouth, N. H. As early as 1773 he had made several visits to Rhode Island, preaching to large congregations in Newport, East Greenwich, and Providence. He formed life-long friendships with Gen. Nathaniel Greene and other distinguished Rhode Island patriots.

Mr. Rely held that the atonement was complete. All men had fallen in Adam, through "union" with him had actually participated in his transgression, and therefore merited damnation. But in like manner all, through "union" with Christ, the second Adam, had entered into the atonement. Their redemption, though not their salvation, was complete. Murray accepted this doctrine without qualification. Supposing himself to be entirely alone in his views on this continent, he did not make formal announcement of them, but confined his expression entirely to the language of the Scriptures. Hence his deviation from orthodoxy for some time was not suspected, and churches of the standing order were freely opened to him. But as men came to have a clearer understanding of his opinions he encountered opposition. While preaching in Boston in 1774 his life was threatened. Visiting Gloucester, Nov. 3, 1774, he found several persons who had read Rely's *Union*, and were thoroughly in accord with its teachings. Being invited to settle in Gloucester, he accepted, and barring the term of his chaplaincy in the army, resided here until his removal to Boston, in 1793, where he remained until his death. Through Murray's influence a number of societies were established in different parts of the country. Among his associates in the work of the ministry may be mentioned Adams Streeter, Caleb Rich, Edward Mitchel, George Richards, a man of lofty eloquence and literary power; Walter Ferris, Elhanan Winchester, and Hosea Ballou.

Mr. Ballou exerted a greater influence than Murray upon the Universalist denomination and theology. He was born in Richmond, N. H., April 30, 1771, of Baptist parentage, but before he was 18 years old he had become persuaded that the Scriptures taught that the grace of God is universal, and a few years later he had cast aside the commonly received notions of the Trinity, and the atonement. After being ordained to the ministry in 1794 his settlements were Dana, Mass.; Barnard, Vt.; Portsmouth, N. H.; Salem, and Boston. In the autumn of 1798 he supplied Mr. Murray's pulpit for ten weeks. "On the last day of his ministration he gave a very frank and clear explanation of his new views touching Christ and the atonement." The occasion is historic. It marks a new departure in the Universalist theology of the period. From that time every vestige of Calvinism was swept out of the Universalist faith. In 1804 Ballou published *Notes on the Parables of the New Testament*, and in 1805 his *Treatise on the Atonement*. Horace Greeley and others have called this the most remarkable book of the century. It was remarkable, if it be remembered, that a young man without formal education, unacquainted with the literature of theology, without commentaries, with nothing but the English Bible, had substituted the moral for the legal view of the atone-

ment, and produced a system of theology, with Christ as the mediatorial agent for bringing the moral universe into voluntary subjection to the power and love of God. His theology, however, has never been wholly acceptable to the Universalist body. He held an extreme view of the Divine sovereignty which gave an Antinomian tinge to his teaching. His theory that "the Scriptures begin and end the history of sin in flesh and blood, and that beyond this mortal existence the Bible teaches no other sentient state but that which is called by the blessed name of life and immortality," gave rise to the Restorationist movement, and led many to feel that the Universalist view of sin is superficial and frivolous. Yet, under his influence, the denomination had a phenomenal growth. People flocked in multitudes to hear his messages, and he drew into co-operation with him men whose intellectual gifts were only inferior to his own. Mention should be made of Walter Balfour, whose examination of the meaning of the terms Sheol, Hades, Tartarus, and Gehenna, led to interpretations which have now been accepted by the foremost scholars and Biblical critics of the Protestant world; Thomas Whittemore, an unrivalled controversialist, and Lucius R. Paige, known by his books, *Selections from Eminent Commentators*, and *Commentary of the New Testament*. The historical outline of Universalism would not be complete without reference to two other men, who, though belonging to a later generation, were contemporaries of Hosea Ballou in the formative period of the denomination. The first is Hosea Ballou, second editor of the *Universalist Quarterly Magazine*, from 1844 to 1861, and the first president of Tufts College; a scholar of the first rank. The second is Thomas J. Sawyer, the dean of Tufts Divinity School. To these two men the denomination is indebted for the shaping of its theology, and for the educational impulse which has been a conspicuous feature of its later history.

The General Convention, at its session in Winchester, N. H., in 1803, adopted the following:

I. We believe that the Holy Scriptures of the Old and New Testaments contain a revelation of the character of God, and of the duty, interest, and final destination of mankind.

II. We believe that there is one God, whose nature is love; revealed in one Lord Jesus Christ, by one Holy Spirit of grace, who will finally restore the whole family of mankind to holiness and happiness.

III. We believe that holiness and true happiness are inseparably connected, and that believers ought to be careful to maintain order and practice good works, for these things are good and profitable unto men.

This profession has remained the only test of fellowship until the present time. There is, however, a large and increasing minority who object to it on the ground, first, that the last clause of the second article seems to imply the doctrine of the fall of the race through the transgression of Adam; and secondly, that the third article is utilitarian in its philosophy. A committee has been appointed by the General Convention to consider the matter of revision.

Polity.—Universalists originally for the most part were drawn from the Congregationalists. Accordingly the polity of the church has Congregational features. In the individual churches the people have the controlling voice in settling ministers and directing parish affairs. The parishes are organized into conventions confined to the limits of the several States, the General Convention being over all. The State conventions are composed of the clergymen in fellowship, and of lay delegates chosen by the parishes. Discipline is in the hands of a committee of fellowship, appointed by each convention. The General Convention is a delegate body, meeting, after 1889, biennially. Delegates, clerical and lay, in certain definite proportions, are chosen by the State conventions. It is also a corporate body, having a board of trustees, who

are charged with matters of discipline, finance, and missionary effort. The General Convention was chartered in 1866. The present organization dates from 1870.

Statistics.—The whole number of ministers is 710. There are 926 parishes, comprising about 40,000 families. The church-membership is upwards of 37,000. There is a Sunday-school membership of nearly 53,000. The estimated value of church property is \$7,500,000. The permanent funds of the general convention aggregate nearly \$200,000. During the last thirty years particular attention has been given to the establishment and development of educational institutions. Besides such seminaries as Clinton Liberal Institute, in New York; Goddard Seminary, in Vermont; Westbrook Seminary, in Maine, and Dean Academy, in Massachusetts, all well endowed, there are four colleges and three theological schools. The colleges are Tufts College, St. Lawrence University, Lombard University, and Buchtel College. With each of the three first-named colleges a theological school is connected. The aggregate of funds permanently devoted to educational purposes is not less than \$3,000,000. Upwards of 100 teachers are employed, and instruction is given to nearly 1400 pupils annually. (E. H. C.)

UNIVERSITIES. See **COLLEGES.**

UPHAM, CHARLES WENTWORTH (1802-1875), author, was born at St. John's, N. B., May 4, 1802. His father, Joshua Upham (1741-1808), was a judge in Massachusetts, but taking the Tory side in the Revolution, removed to New Brunswick, where he became member of the governor's council. Charles returned to Boston in childhood and graduated at Harvard in 1821. Three years later he was ordained as a pastor in Salem, but after twenty years' service he was obliged to give up preaching on account of loss of his voice. Meantime he had already served in the Legislature, and was afterwards a member of the State Senate, and its president in 1857-58. He was also a member of Congress 1853-54, and took part in the original organization of the Republican party. He died at Salem, June 14, 1875. He had always been busy in writing for the press; his *Lectures on Witchcraft* (1821) was afterwards expanded into two volumes (1867); he edited the *Christian Review*, quarterly, and the *Christian Register*, weekly; and prepared several biographies: *Sir Henry Vane* (1835) for Sparks' *American Biography*; *Fremont* (1856); *Francis Peabody* (1869), and completed the *Life of Timothy Pickering* (5 vols., 1867-72), which had been left unfinished by O. Pickering. He also prepared a *Life of Washington*, made from the general's letters, but withheld it out of regard for Sparks' edition of the *Writings of Washington*. A surreptitious edition, however, appeared in England in 1852.

UPHAM, FRANCIS WILLIAM, educator and author, was born at Rochester, N. H., Sept. 10, 1817. He graduated at Bowdoin College in 1837, studied law and was admitted to the bar in 1844. He afterwards devoted himself to teaching in New York city, where he was professor of mental and moral philosophy in Rutgers Female College, 1867-70. Being greatly influenced by the views of Prof. Tayler Lewis, he has published not only a defence of these views, but also other religious works, containing peculiar and ingenious speculations. They include *The Wise Men* (1869); *The Star of Our Lord, or Christ Jesus, King of all Worlds* (1873); *Thoughts on the Holy Gospels* (1881).

UPHAM, THOMAS COGSWELL (1799-1872), author, was born at Deerfield, N. H., Jan. 30, 1799. His grandfather, Timothy, had been the pastor of the Congregational church there for many years, his father, Nathaniel, had been a member of Congress for three terms, and his uncle, Timothy, was an officer in the war of 1812. Thomas graduated at Dartmouth College in 1818 and at Andover in 1821. Here he became tutor of Hebrew, but in 1823 he was made associate-pastor at Rochester, N. H. In 1825 he was called to Bow-

doin College, and there held the chair of philosophy for forty-two years. During this time he prepared his *Elements of Mental Philosophy*, in three volumes, treating respectively of the intellect, sensibilities, and will. An abridged edition also had a large circulation as a text-book in schools. He also published *Life and Opinions of Madame Guyon* (1847); *Life of Faith* (1848); *Divine Union* (1851); *Letters from Europe, Egypt, and Palestine* (1857). He resigned his professorship in 1867, and took up his residence at Kennebunkport, Me. He died at New York city, April 2, 1872.

UPTON, EMORY (1839-1881), general, was born Aug. 27, 1839, at Batavia, N. Y. He was brought up on a farm, and spent the winter of 1854-55 at Oberlin College, Ohio, but in 1856 entered the U. S. Military Academy at West Point. He graduated on the outbreak of the war in 1861, and was assigned as 2d lieutenant to the 5th regiment of artillery. On May 27 he was selected as aide to Gen. Tyler, and as such was present at the first battle of Bull Run, where he was wounded. On his recovery he was assigned to the command of a battery in the U. S. artillery in Franklin's division, and was commended by that general and again by Gen. Slocum for skill and bravery in the Seven-days' fight. At the battles of Crampton Gap and Antietam, Upton was in command of an artillery brigade of 26 guns which he handled with marked efficiency. In October, 1862, he was appointed colonel of the 121st N. Y. Volunteers, and so distinguished himself at Salem Heights (May 3, 1863) that, at Gettysburg, he was intrusted with the command of a brigade. Holding the same position he took part in the assault on the Confederate intrenchments at Rappahannock Station (Nov. 7, 1863). He participated in Gen. Grant's Wilderness campaign in May, 1864, and distinguished himself particularly in the indecisive battle at Spottsylvania Court-House. Promoted brigadier-general of volunteers, in May, 1864, he took part in the defence of Washington in July, as well as in Sheridan's campaign against Early in the Shenandoah Valley, again distinguishing himself at the battle of Winchester (Oct. 9, 1864), where he was severely wounded. He was then promoted major-general of volunteers, and, on his recovery, was assigned to the command of the fourth division of the cavalry corps under Gen. J. H. Wilson and participated in that general's operations in Alabama and Georgia, from March to May, 1865, taking part in the capture of Selma and Columbus. On March 13, 1865, he was promoted brevet major-general U. S. A. At the close of the war he was assigned to the command of the district of Colorado with head-quarters at Denver. Devoting himself now to the study of tactics, he developed the system used in the U. S. army under his name. In 1875 he was sent out by the government as a special commissioner to investigate the military condition of the various countries in Asia and Europe, and gathered valuable material for his authoritative work on the military policy of the United States. On being mustered out of the volunteer service in April, 1866, he resumed his rank as captain in the 5th regiment of artillery, but in July he was made lieutenant-colonel of the 25th infantry; and in 1870 was appointed commander of cadets in West Point, which office he held for five years. On his return from his foreign tour in 1877, he was assigned to duty at the artillery school of practice at Fortress Monroe. He died by his own hand, March 14, 1881, at Presidio San Francisco, whither he had gone in the close of 1880 to assume command of the 4th artillery, of which he had been appointed colonel. His death is attributed to despondency caused by chronic catarrh. His publications were his standard work on *Infantry Tactics* (1867) and his *Armies of Asia and Europe* (1878). Prof. Michie has published his *Memoir* (1885).

USURY is the excess over the legal rate charged to a borrower for the use of money. The legal rate is

fixed by statute in each State; if there be no statute there can be no usury in a legal sense. See Vol. XXIV. If there be a loan in contemplation of p. 17 (p. 22 Am. Rep.). the parties, no matter how it may be disguised, the contract is usurious if it be so in other respects. The *bona-fide* sale of a note, bond, or other security at a greater discount than would amount to legal interest has been held not to be necessarily a loan, though, if the note was made with a view to evade the law against usury, the transaction would be construed a loan. Both parties must be cognizant of the facts which make the contract usurious. It has been held that a mistake in regard to the law will not protect the parties, though a miscalculation will. A mortgagor may, however, agree to pay a tax on the mortgage in addition to the full legal rate of interest. The ordinary commissions in the course of trade may be charged without making a contract usurious, though not so if they are charged as a means of evading the law. A commission charged in addition to interest for advancing money is usurious. A gratuity given to influence the making of a loan has been considered to be usurious. The reserving of interest on negotiable paper at the time of making the loan does not make the contract usurious, though the borrower is thereby made to pay more than the legal rate. The borrower must be obliged to return the principal together with more than lawful interest. Parties may contract for interest according to the place of the contract or the place of performance. In the absence of such agreement the transaction will be governed by the law of the place of the contract. When a dispute about interest is taken before a court the burden of proof is on the person pleading usury.

Usury may be set up as a defence by the person who has contracted to pay usurious interest, or by his sureties. A usurer, however, cannot take advantage of his usury to avoid his contract.

It is generally provided by the statutes of the States that the excess over the legal rate of interest is not recoverable.

The act of Congress of June 3, 1864, provided with reference to the national banks that they might take interest at the legal rate of the State, Territory, or District where the bank was located, except that in a State where the State banks were permitted to take a higher rate, the national banks might do the same. If no rate was fixed by the law of the State, Territory, or District, the banks might not exceed 7 per cent. It was further provided that the penalty for taking a greater amount of interest than that allowed by the act should be deemed a forfeiture of the entire interest carried by the note, bill, or other evidence of debt; also that where such interest had been paid, twice the amount thereof might be recovered back by the person who had paid it, provided the action was begun within two years. Under this act it has been held that as Congress is the sole judge of the necessity for national banks, and has created them, the States cannot exercise control over them or in anywise affect their operation, except so far as Congress may permit; consequently the penalty prescribed by the Act of 1864 for the exaction of usurious interest is superior to and exclusive of any State penalty. It has also been held that a national bank is not justified in charging usurious interest because the statute of the State permits specified banks to do so. (T. R.)

V.

VACCINATION. This operation consists in the See Vol. XXI. inoculation of the human subject with p. 23 (p. 28 Am. Rep.). the lymph of cow-pox or kine-pox (*vaccinia*), for the special purpose of preventing an attack of small-pox (*variola*), and it is believed to be almost as sure protection against that loathsome disease, when properly performed with pure virus, as is small-pox itself a protection against a second attack. Furthermore, it modifies the severity of small-pox and greatly reduces the death-rate from that disease in its modified form, *varioid*. To Edward Jenner, an obscure apprentice and country physician at Sodbury, near Bristol, Eng., is due the credit of discovering the prophylactic properties of *vaccinia*, his attention being first called to the immunity from small-pox of persons connected with the care or milking of cows, and whose hands became sore from coming in contact with the udders and teats of cattle suffering with a peculiar eruption about those parts. He first published to the world his great discovery in 1798, after a series of observations and experiments extending over a period of twenty years, and although bitterly opposed at first, his name has become immortal among all civilized nations as one of the greatest benefactors of the race.

The phenomena resulting from vaccination are: A slight papular elevation is observed at the point of inoculation (usually about midway between the elbow and shoulder) on the evening of the second or morning of the third day after the operation, becoming more distinct and reddened on the fourth day, and presenting a bluish-white vesicle about the fifth or sixth day, with raised, firm edges and marked central depression (umbilicated) on the seventh day. The pock attains its growth by the eighth day, and appears as a plump

round, pearl-colored vesicle, distended with clear lymph elevated two or three lines, and measuring about one-third inch in diameter. At this time a circular ring of inflammation or areola forms about the base of the pock, increasing for a day or two in redness, and measuring from one to three inches in diameter; considerable hardness and swelling may occur in the adjacent tissues, with pyrexia and some local pain and pruritus; occasionally there is inflammation and swelling of the lymphatics of the arm and glands of the axilla. About the tenth day the areola begins to fade, the pyrexia to subside, and a dark spot is seen on the centre of the vesicle, which gradually concretes and becomes opaque, forming a hard scab by the fifteenth day, and falling off about the twenty-fifth day from the date of vaccination, leaving a circular, depressed and somewhat foveated cicatrix, which usually remains visible through life.

Vaccination should be performed in early life, as the susceptibility to small-pox exists at all ages. An infant, if healthy, may be vaccinated after the second month, or even earlier, if exposed to the contagion, care being taken to use only pure vaccine, and it is better perhaps at so tender an age to use humanized lymph (not too far removed) instead of bovine. The length of time during which the protection afforded by vaccination exists has been variously stated—the "seven-year" theory having many advocates. No rule can be laid down on this point, and the safest plan is to revaccinate whenever an epidemic of small-pox occurs in the vicinity or an exposure to the disease has happened. Even if no epidemic or exposure occurs it is good practice to revaccinate those who have indistinct scars or who have not been vaccinated since infancy. Flint recommends revaccination every five years.

The procuring of *pure vaccine* is the most important practical point connected with vaccination, and upon this too much stress cannot be laid; the difficulty of obtaining it is in fact at the bottom of all present opposition to humanized virus (except, of course, the few non-believers in the whole subject of vaccination), and in this country bovine virus has nearly superseded the use of the old-time "scab" or "crust," and "vaccine tubes." Quite recently (1887) John B. Buist, M. D., F. R. S. E., in his book, *Vaccinia and Variola, a Study of Their Life History*, says: "The difficulty which is encountered in determining the cause of many infective diseases lies in the circumstance that no definite bacteric form peculiar to them can be isolated; and this is occasioned by the minute forms in which such contagia generally exists. Improved methods of histological investigation, by means of different staining materials and improved magnifying and illuminating apparatus, have now made it possible to define forms which were formerly beyond the range of human vision Experimental vaccination appears to prove that the potency of vaccine materials varies in a remarkable degree, in proportion to the quantity and quality of their active principle The form of bacterium present in clear vaccine lymph is a very minute spore, .15 μ in diameter, and if the lymph be dried immediately the further development of the spore is prevented. Its activity can be revived by moistening the dried film of lymph with water, and this material, when properly employed, produces perfect vaccination. Between this minute body and the large torula (2 μ to 5 μ) cell in opaque lymph, there is apparently no more connection than there is between an acorn and an oak, but there are certain close analogies between vaccine lymph and yeast. In Great Britain, "clear vaccine lymph, carefully taken from typical vesicles in healthy subjects (arm-to-arm vaccinations), is regarded by the authorities of the National Vaccine Establishment as the most perfect material for vaccination that can be obtained. Opaque or opalescent lymph is regarded as an inferior or imperfect material for vaccination, on the ground that complaints used to be frequent, on account of its too energetic qualities. Vaccine lymph is said to be clear when it shows no opalescence by reflected or obliquely transmitted light, and when it is free from blood or other impurities. It is said to be opaque when it appears slightly milky, or opalescent when tested in the same way. One of the great difficulties of vaccination is the propagation of a material which remains perfectly clear for a time after being stored It is found that vaccine lymph is most certain in its action when transferred directly from the arm of one child to that of another, good vesicles being easily produced by a single or a double scratch thus: . . . If this same material be stored in a tube for even half an hour, it is found that the same result cannot be produced unless the operation is done thus: . . . and the lymph well rubbed in it. This explains why many vaccinations fail with clear lymph, especially if they are in the habit of vaccinating from arm to arm. The material has changed in potency, and a more severe operation is required for its successful insertion. When a cover-glass preparation of clear lymph is examined microscopically, it shows minute isolated spherical organisms, about .15 μ in diameter. This is the true bacteric form of the perfect vaccine material, which does not contain any larger organisms. When the lymph is dried, these organisms are preserved from developmental changes, and the material undergoes no other change in quality than is common to stored lymph generally. . . . Opaque vaccine lymph, unless originally clear and carefully stored in well-filled sterilized tubes, from which the air has been expelled during the sealing process, must be regarded as an imperfect material for vaccination. . . . Experience teaches that opaque lymph is an imperfect vaccine material. It is more energetic locally than clear lymph, and in former times eruptions

were frequently produced by its use, especially when the lymph was taken too late."

Owing to the supposed deterioration of humanized lymph (i. e., vaccine obtained from previous vaccinations) and the opposition to its use by many who fear the introduction of other diseases, bovine lymph has almost entirely superseded its employment in this country. The "Beaugency stock," imported to the United States in 1870, by Dr. Henry A. Martin, of Boston, is perpetuated through successive inoculations of heifers, being first obtained from a cow at Beaugency, France, in 1866, in which a "spontaneous" appearance of cow-pox was observed. The inoculation of heifers is performed by securing the animal upon its back, in a frame made for that purpose, shaving the parts adjacent to the udder, and introducing the virus at many points over the denuded surface, which is first thoroughly cleansed. The scarifications are protected by fastening a cloth over the parts, and in due time the vesicles appear. When filled with lymph, on the seventh or eighth day, the calf is again secured as before, and ivory points or quills are "charged" with the virus as rapidly as possible, dried, and hermetically sealed, or otherwise protected from the air. It is a remarkable fact that bovine virus does not retain its potency as long as the humanized, and for this reason the ivory points or quills are not guaranteed by those furnishing them beyond two or three weeks. No lancet is required in the operation, as each point or quill is sharpened at the end sufficiently to scarify the place of inoculation, care being taken to first dip it in water to liquefy the virus. Simply removing the outer or scarf-skin with the ivory point, or making cross cuts thus . . . , with a lancet, without drawing blood, is deemed the best practice. It is claimed that better protection results if more than one, say four or five vaccinations, are made (see table below), and that the inconvenience or discomfort from inflammatory action, etc., is not thereby increased; this applies more particularly to humanized vaccine.

The following classification of 5000 patients—extending over twenty years—afflicted with small-pox, shows the percentage of deaths in each class represented (Marson):

Classes.	Percent. of deaths.
I. Unvaccinated.....	35.00
II. Stated to have been vaccinated, but showing no cicatrix.....	23.57
III. Vaccinated— <i>a</i> , one cicatrix.....	7.73
<i>b</i> , two cicatrices.....	4.70
<i>c</i> , three ".....	1.95
<i>d</i> , four or more cicatrices..	0.55
<i>a</i> , well-marked ".....	2.52
<i>b</i> , badly ".....	8.82
IV. Having previously had small-pox.....	19.00

The history of the introduction of vaccination into this country shows the same bitter opposition by both the medical profession and the people as marked its early introduction in other countries. Dr. Benjamin Waterhouse, of Cambridge (formerly of Newport), and Dr. James Smith, of Baltimore, are each given the credit of the first vaccinations in the United States. In June, 1800, Waterhouse, who was then professor of theory and practice of medicine in Harvard, and who had obtained all the information possible regarding Jenner's great discovery, succeeded after several fruitless efforts in obtaining upon a cotton thread a small quantity of pure vaccine from England, and on July 8 inoculated one of his sons, then five years of age. This he followed in a few days by vaccinating others in his family, six in all, among them an infant of one year. He then applied the crucial test by sending the children to the small-pox hospital at Brookline, within two months after their vaccination, where they were not only freely exposed to the contagion of small-pox but also inoculated with variolous matter, the only result observed being a very slight irritation at the

points of the insertion of the virus; there was no constitutional disturbance whatever. Waterhouse very truly remarks: "One fact in such cases is worth a thousand arguments" (*The Jenner of America: an address delivered before the Philadelphia Co. Medical Society by W. M. Welch, M. D., 1885*).

Notwithstanding his successful experiments with vaccination, all efforts to establish a vaccine centre in Boston failed; but Waterhouse had a firm friend in Thomas Jefferson, President of the United States, to whom he sent vaccine, and who in turn supplied physicians in the District of Columbia, Pennsylvania, Maryland, Virginia, and other States still farther south, also the Indians; studying the phenomena of the disease himself very closely, and learning by observation that the proper period for collecting the virus is "eight times 24 hours from the time of its insertion." This rule, which the President himself observed carefully and with uniform success, he was particular to communicate to all to whom he sent virus (Welch). Waterhouse made repeated efforts to establish a vaccine institution in Boston, but failed, though his perseverance finally settled the question of the value of vaccination in the following manner: The Board of Health of Boston appointed a committee of seven of the most reputable physicians of the city, who on Aug. 16, 1802, vaccinated nineteen children at the health office. On Nov. 9 these children were sent to Noddle's Island, and there inoculated two different times with variolous matter, besides being exposed for twenty days to the *contagium* of small-pox without manifesting the slightest indisposition. The report of the committee concludes with this remark: "The cow-pox prevented their taking the small-pox, and they do therefore consider the result of the experiment as satisfactory evidence that the cow-pox is a complete security against the small-pox" (Welch). A similar test at Randolph, Vt., where the question of inoculation with small-pox vs. cow-pox was to determine the efficacy of the latter; a town-meeting was held, a committee appointed, and 75 persons who had been vaccinated were then inoculated with the small-pox virus taken warm from the pustules of patients covered with them, and not one of the number was found susceptible to small-pox. The committee, however, was not satisfied, and desired to find some woman with a sucking child who would be willing to let her infant be vaccinated and herself have small-pox. Waterhouse says: "Mrs. M—heroically offered herself for the experiment. The infant was first inoculated with kine-pox, and forty-eight hours afterwards its mother was inoculated with small-pox. The kine-pox went on regularly in the child, and so did the small-pox in the mother, who suckled the child all the time. The mother had a considerable number of pustules on her body, face, and breasts; one or two of which were kept raw by the tender lips of the infant while sucking; and yet the child appeared as well throughout the whole process as if it had not been nursed by a person suffering under small-pox" (Welch).

Dr. Henry A. Martin says of the opposition to Waterhouse by the clique of Boston physicians that it "did all it could to oppose vaccination (as taught by Jenner), to hinder, vilify, and persecute the noble man, who, in the face of obstacles innumerable, struggled for the truth and won—won what? Poverty, persecution, bitter and mendacious, and a fame so great and lasting that only here and there an eccentric student knows more than his name" ("Jefferson as a Vaccinator," *N. C. Med. Journal*, January, 1881). In 1810 he petitioned the Legislature of Massachusetts to reimburse him for the work he had done, having impoverished himself by his long-continued efforts in establishing vaccination in his own and other States. The Legislature satisfied itself by permitting him to withdraw his petition! In a letter to an old friend in England he says: "For the honor of my country I

am ashamed to tell Dr. Jenner how I have been treated by our Legislature respecting remuneration. I have received nothing but abuse, nay, more, I have been intrigued out of my place as physician to the U. S. Marine Hospital, with 500 sterling a year, and given me by Jefferson as a reward for my labors in vaccination, and this merely in consequence of his going out and others coming in, so that, at 56 years of age, I have now to contrive and execute some new plan to supply this deficiency." After he was forced out of the university by his jealous associates, President Madison, knowing of his unfair treatment, gave him military supervision of the nine posts of New England.

Dr. James Smith, of Baltimore, began vaccinating in that city in the spring of 1801, contemporaneously with Waterhouse's second effort in Boston, but, unlike him, met with no opposition professionally or otherwise; "on the contrary, the profession of Baltimore, including almost the entire faculty, gave public and early expression of their approval," and vaccine virus was distributed through his efforts "over Pennsylvania, New York, New Jersey, Delaware, Maryland, Ohio, Kentucky, Virginia, North and South Carolina, and other States, and even to the West Indies and South America" (*The Introduction of Inoculation and Vaccination into Maryland Historically Considered*—Address by J. R. Quinan, M. D., Baltimore, 1883). It is stated by Dr. Quinan that the first virus received into Baltimore was by Dr. John Crawford of that city in the summer of 1800, contemporaneously with the first received by Waterhouse. Notwithstanding the assistance given Dr. James Smith, he, too, became impoverished in his enthusiastic efforts to disseminate the "new inoculation," as it was then called. The vaccine institute established by him and his associates in 1802, and his work to further its beneficial effects, rendered him almost penniless, and when in 1809 the Legislature enacted a law to establish an institution for the free distribution of matter he tried to obtain an appropriation but failed. A lottery was then tried, but as it had to compete with the Washington Monument Lottery it also failed. Subsequently he succeeded in mortgaging his private property and establishing a vaccine institution in the city; and in 1813, Congress having established a U. S. vaccine agency, Dr. James Smith was appointed without pay to fill the position of agent, which he held till 1822, when it was abolished (Quinan). Like Waterhouse he early subjected his two sons and other members of his family to small-pox inoculation as a proof of the efficacy of vaccination, and supported twenty special agents with horses and virus to gratuitously vaccinate all who would submit to it.

From the date of these two noble men to the present time the work of vaccination in this country has been going on, until now there is not a city, town, or hamlet in which it is not practised; nor is there one in which epidemics of small-pox are not always successfully met by vaccination; and in most of them there are laws or ordinances compelling vaccination of their school-children, if not of their entire population.

Revaccination.—Although the protection of a successful vaccination is absolute for the time being, accumulative evidence goes to prove that it is not permanent and that revaccination is necessary to thoroughly protect the individual and the community. To insure perfect immunity from the ravages of small-pox it is therefore necessary to revaccinate from time to time. Dr. Wm. M. Welch, physician in charge of the Municipal (small-pox) Hospital, Philadelphia, says:

"Some of the earliest and most conclusive proofs of the value of revaccination are furnished as the result of experience in the Wurtemberg, Bavarian, and especially in the Prussian armies. Among 14,284 re-

vaccinated soldiers in Wurtemberg only one case of small-pox occurred in five years, and only three among 26,964 revaccinated civilians. During three severe epidemics of small-pox in Copenhagen, between the years 1828 and 1835, not even a single instance of varioloid was observed among any who had been vaccinated. . . . It is due to Germany to say that vaccination is nowhere more carefully and thoroughly performed than in that country. It was there that revaccination was first practised and has ever since continued to be systematically performed. . . . During the Franco-Prussian war small-pox prevailed to an alarming extent, and both armies were freely exposed to the contagion; but the loss by death from that disease in the German army was only 263 men, against 23,468 in the French army, and the latter army was at no time much more than one-half the size of the former. In joining the French army vaccination was not a prerequisite, and revaccination was in nowise compulsory. Among the most conclusive proofs of the efficacy of revaccination is that furnished by statistics of small-pox hospitals. After thirty years of labor at the hospital of London, Marson asserted that but few patients were admitted who had been revaccinated with effect, and that these few had varioloid in a very mild form. During his connection with the hospital he revaccinated all the nurses and servants, who had not had small-pox, on their coming to live at the hospital, and not one of them contracted the disease. At a time, however, when a large number of workmen were employed about the hospital, most of them consented to be revaccinated, but there were a few who declined. Of the latter two took small-pox, while the former enjoyed perfect protection.

"The medical superintendents of the several small-pox hospitals of London report that during the period from 1876 to 1879, when 11,412 cases of the disease occurred among vaccinated persons, not one case was known to occur in any person who had been successfully revaccinated. Of the nurses and servants employed at the various hospitals, numbering in all about 1000, some half dozen only contracted the disease, and these for some cause or other had escaped revaccination before entering the wards."

Dr. Welch concludes by saying that his twelve years' service entirely agrees with the above, and that no employé or attendant who had been revaccinated before entering on duty had suffered with the disease.

The question of the identity of small-pox and cow-pox virus, while still discussed, is now pretty generally decided in the negative, and the efficacy of horse-pox vaccine as a protection against small-pox has also been decided the same way. Retro-vaccination (from man to cow) is uncertain and not to be encouraged, the only pure source being the "spontaneous" vaccinia of the cow, which is continued and kept pure through the vaccination of healthy heifers. (P. H. B.)

VALENTINE, EDWARD VIRGINIUS, sculptor, was born at Richmond, Va., Nov. 12, 1828, his father being a merchant in that city. He went to Europe in 1859 and studied first with Couture at Paris, then at Florence with Bonaruti; and after a tour in the art galleries of Italy, at Berlin, with Kiss, with whom he remained for four years. On returning to Richmond Valentine produced portrait busts of Beauregard, J. E. B. Stuart, "Stonewall" Jackson, and other Confederate celebrities. His *Lee Recumbent* (see *SCULPTURE*) was executed for the mausoleum attached to the chapel of Washington and Lee University. Valentine had already spent some time at Lexington, Va., modelling a bust of Gen. Lee, and was thus well fitted for the later task. He has also produced several ideal figures and groups, the most noted being *Andromache* and *Astyanax*. His bronze heroic statue of John C. Breckinridge, ordered by the State of Kentucky, was erected at Lexington, Ky., in November, 1887. His latest work is a statue of "Stonewall Jackson" for the Jackson Memorial Association.

VALLANDIGHAM, CLEMENT LAIRD (1820-1871), politician, was born at New Lisbon, Ohio, July 29, 1820, of a Dutch family long settled in Virginia. The name was originally Van Landeghem. His mother's Scotch-Irish blood also entered into his tenacious combativeness. After teaching school two years in Maryland and acquiring the art of stump-speaking, he became a lawyer at Columbus, Ohio, 1842, was sent to the Legislature 1845-47, edited the *Western Empire* at Dayton 1848-50, and was an unsuccessful candidate for several offices. Of unblemished private character and untiring industry and energy, his extreme Southern opinions long excluded him from public life; but after repeated efforts he in 1857 secured a seat in Congress. He always professed to be for the Union, but he was the most resolute, persistent, and annoying opponent of war measures in the North—the model and leader of such as were called Copperheads. The House heard a resolution to inquire concerning his loyalty, Feb. 19, 1862, and received seven petitions for his expulsion. He was in constant anticipation of public punishment or private violence, but nothing short of imprisonment or death could silence him. The same zeal and courage, exerted on behalf of the North, would have won him a high place in national history. When his last term in Congress had ended he kept up his agitation by frequent speeches in Ohio. Anywhere but in the United States he would have been suppressed at once. For a speech at Mt. Vernon, May 1, 1863, he was arrested May 5, by order of Gen. Burnside, commanding the department of the Ohio, tried by court-martial, and sentenced to be confined in Fort Warren, Boston harbor. Pres. Lincoln, who, perhaps, preferred to make his foe ridiculous, commuted this to deportation beyond the lines. Vallandigham was escorted to the Confederate troops in Kentucky. His friends protested, and Lincoln justified the banishment of one who was striving "to prevent the raising of troops, to encourage desertions from the army, and to leave the rebellion without an adequate military force to suppress it." The exile made his way to Canada, was nominated for governor of Ohio in his absence by the Democrats, and defeated by an enormous majority. He returned home in June, 1864, and was not further disturbed, for the tide of war had turned and he was no longer dangerous. His death at Lebanon, O., June 17, 1871, was highly sensational. He was arguing a murder case in court, and in attempting to illustrate the tragedy another was produced by the explosion of a pistol in his hand. His *Speeches, Arguments, Addresses, and Letters*, with a sketch of his life, was published in 1864 as an extended campaign document.

VAMBERY, ARMINIUS, a Hungarian explorer of Central Asia, was born at Duna-Szerdahely, on an island in the Danube, 1832. He was educated March 19, at Presburg and Vienna, and was a private teacher at Pesth when the revolution of 1848 broke out, and naturally joined in the movement. At the siege of Comorn his leg was broken, but this fact probably saved his life when the Austrians became masters of the place. He was, however, exiled and took refuge at Constantinople. Here he improved his opportunities to become acquainted with the Asiatic languages, and finally he determined to visit the native land of the Huns. First he spent nearly two years in the Ottoman embassy at Teheran, then adopting the disguise of a dervish he joined a band of pilgrims on their way to Turkestan. He visited Khiva, Bokhara, and Samarcand without detection, and on his return to Europe brought with him a genuine dervish whom he had deceived by a pretence of visiting Mecca. His contributions to ethnographic and geographical science were warmly welcomed by the learned societies of Europe. His book, *Travels and Adventures in Central Asia* (London, 1864), was issued in several languages. His later books have regard to the same general theme. They include

Wanderings and Adventures in Persia (1867); *Sketches of Central Asia* (1868); *History of Bokhara* (1873); *Mohammedanism in the Nineteenth Century* (1875); *Manners and Customs in Oriental Countries* (1876); *Primitive Civilization of the Turco-Tartar Peoples* (1879). He has published a *Dictionary of the Turco-Tartar Languages* (1878) and an autobiography, *Life and Adventures* (1883). His recent works are *The Origin of the Magyars* (1882); *The Turkish Tribes* (1885); *The Coming Struggle for India* (1886). He has also translated *The Scheibaniade*, an epic poem of the Usbeks (1885).

VANDERBILT, CORNELIUS (1794-1877), capitalist, was born near the site of Stapleton, Staten Island, N. Y., May 27, 1794. His condition was humble, and education he neither possessed nor valued; but his financial talent has never been surpassed. At sixteen he bought a boat to carry farm products to New York; at twenty-three he had amassed \$10,000. Then he became captain of a steamboat plying between New York and New Brunswick, where his wife aided him by keeping a hotel. He remained in the service of Thomas Gibbons till 1829 on a salary of \$1000, and raised the business to \$40,000 a year; then, refusing his employer's offers, he embarked in the building of steamboats to run on the Hudson, Long Island Sound, and elsewhere; hence his title of "Commodore." His enterprise, daring, and persistence were rewarded by uniform success. He was unmerciful to competitors, but he was true to his word and had a rough sense of honor. About 1848 he began to extend his maritime operations. In 1851 he started a line of vessels to San Francisco by way of the Isthmus, with a branch to New Orleans in 1852. The next year he took his family abroad in one of his ships, and in his absence was dropped from the management of the California routes. For this, as in other cases, his vengeance was prompt and effective. He built a rival line, which compelled the other to come to terms. He also established a line to Havre, which was given up at the outbreak of the civil war. His first and chief act of generosity was in presenting to the government the "Vanderbilt," which had cost \$800,000. At seventy his gains amounted to forty millions, much of which was invested in railroads. On these he now concentrated his activities, acquiring control of the Harlem. His only mistake (which he ascribed to bad advice of others) lay in attempting to gain command of the Erie, of which Fisk and Gould were ready to issue as many shares as he chose to buy. He established the New York Central system, and by means of its additions was the originator of trunk lines in the United States. After 1873 he managed 2000 miles of track. His statue, with emblematic surroundings, was erected over the Hudson River Railroad station in New York, 1869. Fast horses and whist were his recreations, money-making his business and delight; but he helped those whom he liked, and in his later years gave \$700,000 to Vanderbilt University at Nashville and presented a church to Dr. C. F. Deems. He died at New York, Jan. 4, 1877, worth nearly a hundred millions. See *The Vanderbilts: the Story of their Fortune*, by W. A. Croffut (1886).

His son, WILLIAM HENRY VANDERBILT (1821-1885), was born at New Brunswick, N. J., May 8, 1821. His father, who had little faith in his abilities, left him to make his own way and gave him no assistance till satisfied that he could do it. This he proved as a bank clerk, and then on a farm in Staten Island, where also he was for a time receiver of a railroad. He was never permitted to take any part in the "Commodore's" vast enterprises till 1864, when he was associated in the management of the Harlem Railroad. He soon won the paternal confidence and showed himself entirely able to carry on what his father had begun, as well as to hold what he had acquired. He became vice-president of the Hudson River Railroad in 1872, and five years later was his father's chief heir and sole

successor in the railway management. Better educated and a less striking and original personality, he filled scarcely less space in the public eye by reason of his roads and his millions. He inherited the taste for horses and added one for collecting pictures. His only notable benefaction was the gift of \$500,000 to the New York College of Physicians and Surgeons in 1884. He died suddenly at home, Dec. 8, 1885, having doubled his father's huge accumulations. The stocks passed into the control and chiefly into the possession of his sons, Cornelius and William Kissam. The former, who had the early discipline of self-help, is the chief manager, and noted not only for business habits and capacity but for blameless life and active interest in religious and charitable work. He erected, 1887, in New York a fine building for the benefit and convenience of his railway employés. (F. M. B.)

VAN DYCK, CORNELIUS VAN ALEN, missionary, was born at Kinderhook, N. Y., Aug. 13, 1818. He graduated at Jefferson Medical College, Philadelphia, and was sent by the American Board of Foreign Missions to Syria in 1840. He was ordained by the members of the Syrian mission in 1846, and in 1848 was made principal of the missionary seminary. In 1857, on the death of Rev. Dr. Eli Smith, Dr. Van Dyck took charge of the mission press and also of the translation of the Bible into Arabic. On his visit to New York to superintend the printing of this work by the American Bible Society in 1866-67, Dr. Van Dyck taught Hebrew in the Union Theological Seminary. After his return to Beirut he resumed his duties in connection with the mission press and was also physician to St. John's Hospital and professor of pathology in the Syrian Protestant College until 1882. He has since been physician to St. George's hospital. He has edited in Arabic several mathematical and physical textbooks, and also translated the *Westminster Shorter Catechism*, *Schönberg-Cotta Family*, and treatises of various kinds.

VAN RENSSELAER, STEPHEN (1764-1839), the "Patroon," was born in New York, Nov. 1, 1764. He was fifth in descent from Kiliaen Van Rensselaer, a jewel merchant of Amsterdam, who under authority of the Dutch West India Company acquired in 1630-7 an estate of more than 700,000 acres on the Hudson: this was occupied by the family and by their numerous tenants under a peculiar feudal tenure, and confirmed by various orders during the Dutch possession, and by a grant of Gov. Dongan in 1685. Stephen inherited seigniorial rights over some 3060 farms in Albany and Rensselaer counties, including some 436,000 acres; these lands he did much to improve and settle, but would never sell. His mother was a Livingston; and after graduating at Harvard in 1782 he married a daughter of Gen. Philip Schuyler. Throughout life he was active in the service of the State, and held many offices, being in the Assembly 1789, in the New York Senate 1790-5, lieutenant-governor 1795-1801, president of the Constitutional Convention, regent of the State University from 1819, and for a time its chancellor, in Congress 1823-9. In the war of 1812 he commanded the State militia and directed the attack on Queenstown. He took an early and active interest in the Erie Canal, was one of the commissioners from 1816, and for several years president of the board. He directed Eaton's geological surveys, 1821-3, and bore the cost. He will be long remembered as the founder (1824) of the Rensselaer Polytechnic Institute at Troy. To have exercised equal public spirit concerning the disputed and undetermined rights of the tenants on his huge property would have saved the State much trouble and some bloodshed.

The "patroon" system, under which extensive portions of New York had been settled, in which his family had the largest interest, had been advantageous at first, but its evils had been pointed out in 1732, and it was ill adapted to the nineteenth century and to

republican institutions. The tenants through long occupancy had come to regard themselves as practically owners of the soil, and the antique though slight annual payments were felt as burdensome. In case of transfer, one-fourth of the price was claimed by the patroon; special objection was made to these "quarter sales," and their legality questioned. The last possessor of these feudal rights had been careless or lenient in collecting his rents, often allowing them to run on from year to year, till a sum of about \$400,000 was due him. The tenants expected these amounts to be remitted, but he died at Albany, Jan. 26, 1839, without making any such provision. Then the trouble began. Mass-meetings were held in the country, and an accommodation sought in vain; the heirs resorted to writs of ejectment, which were resisted. The sheriff with a large posse was confronted at Reidsville, Dec. 2, 1839, by a throng estimated at 1500. Gov. Seward in a message of Jan. 7, 1840, denounced the tenures as "odious," and in May a bill was passed to settle the difficulties, but without result. The agitation continued; anti-rent associations were formed, and outrages committed by bands of pretended "Indians." The trouble spread to other parts of the State, where the same system existed. Several lives were lost, disorder prevailed, and Delaware county was declared to be in insurrection; many persons were arrested and 22 sentenced to terms of imprisonment. The anti-renters became a strong political party, and contributed to the election of Gov. Young, after making Silas Wright's term a period of embarrassment and alarm. The disturbance lasted for seven years, and constitutional conventions, legislatures, and courts had much to do before the lease-hold system was finally abolished. Van Rensselaer's heirs modified their claims, and parted with much of their land. These events supplied a motive to three of Cooper's novels, *Satanstoe*, *The Chain-bearer*, and *The Redskins*, and to a satiric poem, *Hildenburger* (1855); all these take the side of conservatism and privilege. See F. P. Cheyney's *Anti-rent Agitation* (1887), in the publications of the University of Pennsylvania. Several of the patroon's uncles and cousins rendered service and won military distinction in or since the Revolution; one of his sons attained note as a Presbyterian clergyman, and another as an officer in the civil war.

VASSAR COLLEGE, the first well-equipped institution for the higher education of women, is located 2 miles east of Poughkeepsie, N. Y. It was founded by Matthew Vassar, an Englishman, who came to America in 1796. Mr. Vassar's earnest desire to use his wealth for the public good led him to consider favorably the suggestion of his niece, Miss Booth, that a model school for young women should be established, and the bolder proposition of his friend, Milo P. Jewett, that he should found and endow a college for young women which should rank with the leading colleges for men. After about two years of preliminary work the college was incorporated Jan. 18, 1861, under the name of "Vassar Female College," which title was, in 1867, changed by the Legislature, in accordance with the request of the founder, to "Vassar College." The charter empowered the 29 trustees to have control of the property, to appoint the members of the faculty, and to confer degrees. At the first meeting of the board of trustees, Feb. 26, 1861, Mr. Vassar transferred to that body property valued at \$400,000, including a farm of 200 acres, on which the college was to be built. This gift was afterwards increased by large sums for various purposes during Mr. Vassar's lifetime. At his death he bequeathed more than \$250,000 for the establishing of four funds, viz.: auxiliary, library, art and cabinet, and general repair. At his first interview with the board Mr. Vassar showed keen foresight and great breadth of view in the remarkable speech in which he set forth his hopes concerning the college and his ideas in regard to the education of women. He also stamped the religious

character of the college in saying that all sectarian influences should be carefully excluded, but the "training of our students should never be intrusted to the skeptical, the irreligious, or the immoral."

In 1861 Milo P. Jewett was chosen as the first president. After his resignation in 1864 John H. Raymond was elected. He retained the position until his death in August, 1878. Samuel L. Caldwell, who succeeded him, resigned in 1885. After one year, during which James Ryland Kendrick served as acting president, James M. Taylor accepted the position, which he still holds (1889).

The main building and observatory were completed in June, and it was decided to open the college on Sept. 20, 1865. More than three hundred students presented themselves for admission, some of whom, in anticipation of this opening, had been carefully prepared for college work. The first faculty consisted of the president, lady principal, 8 professors, and 20 assistant teachers. In accordance with the wish of the founder, that men and women should co-operate in the instruction and discipline of the college, three of the professors and all of the assistants were women. In the present faculty six professors and all of the assistant teachers are women.

The college buildings are as follows: Main building (erected 1865), observatory (1865), museum (1866), laboratory (1880), conservatory (1886), gate-lodge, gas-works, boiler- and pump-houses, and farm-buildings. The main edifice was originally 500 feet long and 164 feet broad at the centre, but in 1872 this breadth was increased to 200 feet. The building is constructed of red brick with trimmings of blue free-stone. The central part and the wings are five stories in height (94 feet), while the connecting portions are four. This building contains apartments for the president and other resident officers and for 300 students, rooms for lectures and recitations, a chapel, library, reading-room, offices, parlors, dining-hall, and kitchen. There is a steam-elevator in the centre of the building. As protection against fire the partition walls are all made of brick and extend from the ground to the top of the house, and the long corridors may be quickly divided into five separate parts by means of sliding iron doors connected with fire-proof walls. Ample protection is further afforded by means of a steam-fire-engine and similar appliances.

The library contains about 16,000 volumes. It is a large, well-lighted room, which is open to the students during ten hours of each day. The library fund provides for an annual increase in the number of books. The observatory is located on a slight elevation, a short distance from the college building, and consists of a basement, principal story, and dome. The equatorial telescope has an object-glass 12½ inches in diameter. The observatory contains also a meridian circle with collimating telescopes, clock, and chronograph, portable telescopes, and apparatus for making solar photographs. The gymnasium contained originally rooms for calisthenics, the riding-school, and a bowling-alley; also a society hall and music rooms. In 1872 the riding-school was discontinued, and the gymnasium was remodelled so as to afford suitable accommodation for the departments of natural history and of art. The valuable collections belonging to these departments were then transferred from the main building to the larger rooms in the building now known as the museum. The gymnasium is well equipped with the apparatus used in the Sargent system, and the alumni have raised a fund for the immediate erection of a new building. The Vassar Brothers' Laboratory of Chemistry and Physics was the gift of Matthew Vassar, Jr., and John Guy Vassar, nephews of the founder. It was erected in 1880 and supplied with all modern appliances for the study of physics and chemistry. In 1886 the Eleanor Conservatory, a memorial gift, was added to the college buildings for the use of the botanical department.

The grounds embrace about 210 acres and form a beautiful park in which the students may indulge in various forms of recreation. A lake affords facilities for boating and skating.

A preparatory department, maintained from the opening of the college until 1888, was then discontinued by vote of the trustees. The departments of painting and music were in 1878 changed into schools of painting and music, which have their respective courses of study leading to diplomas. Resident pupils in music or painting are members of the college family and are required to give a portion of their time to collegiate study. Each school has a director, who, together with the president of the college, has entire control of his department.

In the regular course for the degree of A. B. the studies are all prescribed to the middle of the sophomore year and languages to the close of the same year. During the junior and senior years each student submits for the approval of the faculty an election of from 13 to 15 recitation hours per week. Special courses designed chiefly for teachers may be pursued. For admission to these courses the requirements are in general the same as for admission to the regular course, viz., examinations similar to those required for entrance to the leading colleges of the country. To obtain the degree of A. M. or of Ph. D. the candidate must pursue a course of non-professional study approved by the faculty, and must present a satisfactory thesis upon some topic of the work. Seven hundred and sixty-nine young women have received the degree of A. B. and 29 that of A. M. The first honorary degree, LL. D., was given in 1887.

The charge for one year, including tuition, board, and laundry work, is \$400. In addition to the \$100,000 given as an auxiliary fund, there are eight scholarships, yielding \$300 or \$400 annually. These funds are for students in the regular course.

(J. M. T.)

VAUGHAN, CHARLES JOHN, English clergyman, was born at Leicester, Aug. 6, 1816. He was educated at Trinity College, Cambridge, and graduated B. A. in 1838, and M. A. in 1841, and was fellow of his college from 1839 to 1842. Having taken orders he became vicar at Leicester in 1841, and in 1844 was made head master of Harrow School, which position he held fifteen years. In 1860 he was made vicar of Doncaster and rural dean and chancellor of York Cathedral. In 1869 he was made master of the Temple, London, and in 1879 dean of Llandaff. He was a member of the Cambridge University Commission 1858-62, and of the English New Testament Revision Company until the close of its labors in 1881. He has been noted as a preacher, and several volumes of his sermons have been published. Among these are *Memorials of Harrow Sundays* (1859); *Revelation of St. John* (1863); *Church of the First Days* (3 vols., 1863-65); *Authorized or Revised?* (1882); *Philippians* (1885).

VEDDER, ELIHU, artist, was born in New York, Feb. 26, 1836, and had his first art instruction in his native city. Later on he studied also with T. H. Matteson, and under Picot in Paris. For a time he had a studio in New York, but he subsequently removed to Italy, where he has since resided. His works are characterized by fertility of imagination, and broad and vigorous handling. Ideal in motive, they show the desire of the artist to give expression to his emotions and thoughts, and have given rise to much discussion as to their intent and meaning. His more important paintings include *The Lair of the Sea-Serpent*; *Arab Listening to the Great Sphinx*; *The Crucifixion*; *The Lost Mind*; *Roc's Egg*; *Young Marsyas*; and *Cumean Sibyl*. He has also designed a series of strong and original illustrations for Omar Khayyam's *Rubaiyat*. He was elected an associate of the National Academy, N. Y., in 1863, and an academican two years later.

(T. L. W.)

VENTILATION AND WARMING.

VENTILATION consists in changing the air anywhere, whether it be in an enclosed space or an open field, but is generally understood to mean the substitution of pure air for foul air in dwellings, public buildings, hospitals, factories, ships, cars, mines, etc.; in short, wherever man or beast is liable to reinhale his own or others' breath. Formerly the openings of doors, windows, crevices, and chimneys were deemed sufficient (if the subject was thought of, which is doubtful), and it was also supposed that a cold room was a healthy one. In modern times mechanical ventilation by means of fan-wheels was first introduced in cotton-factories, and the improved health of the operatives drew attention to the necessity of pure air in the habitation of man. Although scientists and doctors had long believed and asserted that deleterious gases vitiated the air and made it injurious to human life, and fires were built in the public streets in those days for the purpose of destroying these gases, it is only within recent years that the scientific study of ventilation and its practical application have been deemed of sufficient importance to be incorporated in the plans and specifications of architects and builders. Without entering into the discussion of the chemical constituents of the atmosphere (see **ATMOSPHERE** in the **ENCYCLOPEDIA BRITANNICA**) it may be stated that one cubic foot of pure air per second is what should be allowed every individual, though half that amount is all that is absolutely necessary, and in order that he may not reinhale it a change of air is indispensable, and must be maintained without giving the sensation of an unpleasant draught—say at the rate of one and not to exceed three feet per second.

Warming is the twin problem with **Ventilation**, and the two will be considered together, as they are almost inseparable. In order to properly ventilate and warm a room in winter or keep it fresh or cool in summer, it is of course necessary to remove the vitiated or foul air in the same quantity as the pure air is introduced—they should be simultaneous and interdependent, otherwise there is imperfect ventilation. The problem is how to accomplish this double or reciprocal movement of air without creating unpleasant draughts, and at the same time securing an equable temperature (say, 70° more or less) throughout the room. It is a well-known fact that heated air rises to the ceiling, while cold air, the emanations from the breath and body, the products of combustion, bad odors, etc., are found near the floor; this being the case, it would seem the most natural thing in the world to withdraw the impure air at the point where it is found, the floor, and let the pure air in at or near the ceiling, as the vacuum created by withdrawing the foul air would cause the warm air to descend gradually to the floor.

Ventilation may be either *natural* or *artificial*; the former is divided into (1) Diffusion, (2) Action of the winds or perflation, and (3) Movements made by unequal weights of air. Every gas diffuses inversely as the square root of its density, and rooms are partially ventilated on this principle through crevices and imperfect carpentry, and even through brick and stone walls (Parke). The action of the winds or perflation is uncertain and difficult to regulate—opening windows at top and bottom, inserting slanting boards to direct the wind upward, or special openings made at various points, ventilating tubes with cowls, etc., have all been tried with indifferent success. Movements made by unequal weights of air are more satisfactory—the fire-place and chimney afford a good illustration of this kind of natural ventilation; also the furnace with registers and outlet tubes properly placed; but this partakes of *artificial ventilation*, which will now be considered. This may be divided into plenum or forced ventilation (propulsion) and vacuum or aspiration (extraction). There is much diversity of opinion as to the relative merits of these two kinds of

ventilation, and in some instances they are combined, hot (or cold) pure air being forced in and foul air extracted at the same time. Scientifically considered, one would think that the great elasticity of the air would be an objection to propulsion for the reason that a room could be surcharged with air without necessarily changing it as rapidly as it entered; while on the other hand, by aspiration, it would change at the same rate as it was extracted, on the principle that "nature abhors a vacuum." Theories in ventilation and warming are as numerous as trees in a forest, and it is only by practical tests and experiments that the question can be settled.

The question of "up-draft," or "down-draft," is equally discussed by engineers and sanitarians, and opinion is divided as to which of the two systems is the best. In the first, the extraction of foul air is made from the top of the room, and in the other from the bottom of the room. The former is the system that has been employed in the Halls of Congress for over a quarter of a century, while the latter is coming into more general use in public buildings in recent years.

The change of air necessary to constitute perfect ventilation and warming depends upon the size of the room and number of its occupants. As has already been stated, each individual should be supplied with fresh air at the rate of one cubic foot per second, and to prevent the unpleasant sensation of a draught the movement of air should not exceed 3 feet per second; better if but 1 or $1\frac{1}{2}$ per second. It will be observed that the inlets and exits to the room must bear a certain proportion to its size and the velocity of the air's movements; it then becomes a mere matter of mathematics to determine the question of how much air is needed and how frequently it must be changed. Parke says "it may be fairly assumed that the quantity of air supplied to every inhabited room should be great enough to remove all sensible impurity, so that a person coming in from the external air should perceive no trace of odor or difference between the room and the outside air in point of freshness. Taking the carbonic acid as the index of impurity it appears from experiments made by Dr. De Chaumont and myself that the organic impurity of the air is not perceptible to the senses until the carbonic acid (*i. e.*, the initial and respiratory carbonic acid) rises to the ratio of .6 per 1000 volumes, or .0006 to each cubic foot. Occasionally air may seem pure to the senses when the carbonic acid is .7 or even .8 per 1000 volumes, but the usual rule seems to be when it exceeds .6 the air commences to become perceptibly impure. When the carbonic acid reaches .9 or 1 per 1000 volumes, the air is what is called close and fusty; above this it becomes disagreeable."

How to warm as well as ventilate a room is a question of importance to a large section of our diversified country. Heating without ventilation is no longer deemed prudent, and the best means to accomplish this double purpose is one that is still *sub judice*. The fire-place or grate, the stove of many patterns, the furnaces without number, the steam-pipes or coils, hot-water pipes, radiators, and what not, are to be found everywhere, while the manner of introducing heated air into large rooms and public buildings, even after the kind of apparatus for heating them has been fixed upon, is no easy question to decide. Shall the heat be admitted at the floor and the foul air extracted at the ceiling, or *vice versa*? shall it be forced in (plenum), or shall it be drawn in (vacuum)?—if propulsion is used, a fan-wheel is necessary; if suction is preferred, a heated ventilating shaft, or a fan-wheel (perhaps both), will be required; while a combination of plenum and vacuum will certainly necessitate fan-wheels for each. Then the condition of the outside air has to be considered, whether cold or warm, moist or dry, high wind or moderate, and the point of the compass from which it comes; the

location of the building itself may influence the heating and ventilating of its rooms, while the light employed (candle, gas, or electric) must also receive attention, so that no system can be said to be perfect, however satisfactory it may be under favorable conditions.

The *open fire*, which most closely resembles the sun's heat by direct radiation (and is doubtless the most healthful), may answer for warming and ventilating small rooms, the demands for combustion preventing the air from becoming stagnant and keeping it in constant motion towards the fire-place; but this very movement of air creates a sensation of discomfort, as a draught from the colder portions of the room or from the cracks and crevices around the doors and windows chills the feet and backs of those sitting in front of the fire, for it must be remembered that the air itself is not warmed by the fire. By supplementing the open fire with warmed air from other sources (small furnaces, etc.), or admitting the cold air back of the fire-place, where it is warmed and delivered into the room (radiating grates), the discomfort spoken of may be in great measure obviated.

The *stove* is probably the most economical and most generally used means for warming small dwellings and, when properly made, and set with a view to ventilation, is, next to the fire-place, the most healthful. There are thousands of different patterns of stoves—from the "thermometer stove" of Dr. Arnott, invented in 1838, and the original "Franklin stove" of earlier date, to the styles of the present day. Whatever pattern is used the following points must be considered: The stove should have a large heating surface, and be encased, except at the top, to prevent direct radiation—the object being to heat the air coming into the room and not the persons immediately around it. A fresh air duct from the external atmosphere delivering the pure air inside the casing surrounding the stove will give an equal temperature throughout the room, while the under-draft to the stove will ordinarily remove the foul air by suction, though it is better to have an opening on a level with the floor, connecting with a heated ventilating shaft. An urn or other vessel filled with water should be kept on top of the stove. When the gas is lighted or the room becomes too warm another opening (fitted with a register) near the ceiling and connecting with the heated shaft may be opened occasionally. It must be remembered that the temperature of a room is no index to the purity of the air.

Steam heating is now largely used in public buildings, hotels, offices, and in not a few private residences, and if proper ventilation and indirect radiation is combined with it, no serious objection can be urged against it, or against *hot water heating* (meaning thereby the heat radiated by pipes or coils in the rooms and halls of buildings, and not heating from such pipes placed in basements and conducted through flues to the rooms above). In such cases fresh air from the outside may be delivered among the coils, thus securing indirect with direct radiation, or admitted at the top of the room, care being taken that foul air ducts from openings level with the floor be connected with a warm ventilating shaft. The disagreeable noises resulting from turning the steam into partially heated or cold coils is said to be now obviated by the use of but one set of pipes, the condensed steam (water) returning alongside the steam from the boiler; of course this also does away with the extra valve and drip-cock at the distal end of the set of coils.

Heated air supplied by either furnaces, steam-coils, or hot water pipes located in the basement, is a very common plan for heating fashionable dwellings, large buildings, churches, school-houses, theatres, etc., the heated air being conveyed through ducts built for that purpose, and delivered where wanted. The general plan of such furnaces, coils, and pipes may be briefly stated as follows: The object being to obtain as large

heating surface as possible in order that the cold air introduced may become sufficiently warmed before passing into the various parts of the building, a furnace should be built upon the same principle as a tubular boiler and enclosed to prevent the escape of the air which is being warmed and collected in the dome, sufficient space being allowed between the enclosing walls and the furnace to permit the warming of a certain amount of air introduced from without. Steam-coils and hot water pipes are also arranged to secure the greatest amount of heating surface possible, and similarly enclosed. Small portable furnaces, such as are found in ordinary dwelling-houses, are enclosed by sheet-iron instead of brick, the cold air entering from the bottom and becoming warmed as it passes upward into the drum.

The hot air is now ready to be conducted into the room or hall: the question is, where shall it enter? The consensus of opinion now is, that it should be admitted at or near the floor, for reasons already given. Shall it be drawn in by vacuum, or forced in by propulsion, or shall both aspiration and plenum be employed? If by vacuum, where shall that be applied, near the ceiling or at the floor? As before stated, the Halls of Congress are heated and ventilated by plenum, the heated air in winter and the fresh air in summer being forced in by means of a large fan-wheel, through numerous openings in the floors, carrying with it the dust and other impurities which naturally gather there, while louvers or ridge ventilators are placed at or near the roof. It is claimed, too, that the floor registers are used as cuspidors, and that the general sanitary conditions of the halls is detrimental to health on account of the system of heating and ventilation employed. The more recent and scientific application of the forces of nature as developed by the *vacuum* or *down-draft system* may be here explained: A vacuum is created in a heated shaft outside the building; the rooms or halls to be ventilated are connected with this shaft by numerous ducts opening upon the floor, the number and size of the openings depending on the air space to be ventilated; at or near the ceiling fresh air is admitted through numerous openings and in the same proportion as it is withdrawn below; this in summer or moderate weather. In winter the heated air is admitted near the floor, naturally ascends, and (the openings in the ceilings being closed) distributes itself equally throughout the room and finds its exit at last through the foul air duct openings at the floor. Objection is made that heated air will remain at the top of the room: theoretically it will; but experiments have proved that it does not, when a vacuum is created below; on the contrary it is discharged as rapidly as it enters, but not till after it has become equally diffused throughout the room, the thermometer marking but two or three degrees difference between the top and the bottom of the room. In fact, the expansion of air by heat is only $\frac{1}{273}$ of its volume for every degree (F.) of additional temperature; if it is zero outside and 70° inside, the air in the room will be only one-seventh lighter than the outside air. By placing the ventilating shaft and chimney side by side (carrying them both well up above the building) the former will be sufficiently heated for ventilating purposes in ordinary weather, but on damp mucky days, or in summer, when the chimney is not heated by fire, a small furnace is necessary to create a vacuum in the shaft. An exhaust-fan is substituted for the ventilating shaft, when desired, and acts on the same principle, by creating a vacuum upon the floor of the room which the warm air above at once fills. Both propulsion and vacuum are employed in mines, aboard ships, and for inaccessible spaces.

Pure Air.—The question of obtaining pure air for heating and ventilating purposes is much discussed, many believing that it cannot be had at the level of the lot or street upon which the house is built, and pure air shafts of various heights have been suggested.

Others claim that smoke, cinders, and the products of combustion in a large city would be drawn into shafts and that the air circulating upon the surface of the earth is best. All agree, however, that air from cellars, damp basements, newly made earth, foul streets, or marshy grounds is not fit to use. This question must be settled by the circumstances involved in each case.

The system of ventilating and warming introduced by Gouge of New York, based on the increased force air gains by being gathered into different sized tubes, partially inserted one into the other, and started by means of a gas jet or lamp, is novel and said to be very satisfactory, particularly in large buildings and railroad cars, where it has been pretty extensively adopted.

The Ruttan-Smead system is fast becoming very popular, many school-houses and public buildings being heated and ventilated by it. The principle is the down-draft or vacuum system, with the additional advantage of utilizing the heated air after it has left the rooms or halls by its passing through numerous openings under the floors, thus keeping them warm, and being again collected in a "gathering-room," where it is further used for ventilating the privies and urinals located in the basement, it thence passes into the heated ventilating shaft. The furnace is tubular, and so constructed as to not only secure a large heating surface but also obtain much heat from the gases and smoke before they escape into the chimney. The ventilating shaft and chimney are carried well above the building and are separated by a thin partition which keeps the shaft heated when the furnace is in use, and a small furnace supplies heat when it is not in use or on damp or rainy days. Each room is supplied with a separate fresh air duct entering near the floor, which is so arranged as to let in either warmed air or cold air, or a mixture of both, as may be desired. An examination by the writer of the "gathering-room" and the privies of a twelve-room school-house with 480 scholars demonstrated the practicability of thoroughly deodorizing and drying the deposits, an accumulation of two years from this number of pupils giving off no odor and appearing like a few barrows of dark dry earth, the urine and all moisture having evaporated. The down draft through the privy holes was very strong and constant, and no odors were perceptible.

No other new systems of ventilation and warming have been introduced in late years; perhaps there are none that do not embrace one or more of those already described. (P. H. B.)

VERDI, GIUSEPPE, the foremost of modern Italian composers, was born at Roncole, near Parma, Italy, Oct. 9, 1814, his father being a poor inn-keeper. From his earliest years he manifested a talent for music, and at the age of eight began to receive lessons from the village organist, while also attending a day-school at Busseto. At his eleventh year a liberal amateur of that town received him into his house and put him under the organist of that place, where he already began to write little orchestra-pieces. In 1833, through the bounty of his patron, he was able to go to Milan, and received for three years instruction from Lavigna, maestro in the great theatre, La Scala. Thence he returned to Busseto, and in 1839 married the daughter of his benefactor. Then taking up his residence in Milan, he brought out his first opera, *Conte di San Bonifazio*, at La Scala. Such was its success that he forthwith received a commission from the director for three other operas, to be produced in two years. The first he presented was a comic opera, *Un giorno di regno*, which met with but a cool reception, and this, coupled with the death of his dearly loved wife, determined him to renounce comic opera forever. His next work, *Nabucodonosor*, was performed at La Scala with triumphant success during the carnival of 1842. From that hour the young master took rank among the first composers of the age. His *I Lombardi* appeared at the same theatre in 1843, and his *Ernani* at Venice,

1844. In the succeeding years he produced a series of operas in the same style: *Idue Foscari*, *Giovanni d'Arco*, *Alzira*, *Attila*, *Macbeth*, *I Masnadieri*, *Jerusalem*, *Il Corsaro*, *La battaglia di Legnano* (interdicted at Rome after its first representation in 1848), *Luisa Miller*, *Stiffolia*. The *Macbeth* on its representation at Florence in 1847 was received with such enthusiasm that it led to his being called to London, where he presented his *Masnadieri*, of which the principal role was written for Jenny Lind. This year also his *Jerusalem* was performed with great success at Paris. Deeper yet in impressiveness and showing greater power in characterization are his *Rigoletto* (1851), *Il Trovatore*, his *chef d'œuvre* (1852), *La Traviata* (1853), *I Vespri Siciliani*, (1855) *Simone Bocca-negro* (1857). His other works of this class are *Alfondo* (1857), *Un ballo in Maschera* (similar to Auber's *Masked Ball*), *La forza del Destino* (brought out at St. Petersburg in 1863 and held by some to be his highest achievement), *Don Carlos* (1866), *Aida* (1871), and *Montezuma* (1878). His last work, *Otello*, founded on Shakespeare's tragedy, was produced at La Scala, Milan, in February, 1887, with great enthusiasm. Besides operas Verdi wrote a series of church and chamber pieces, the best known of which probably are *Romanzi*, a hymn for the second London Exhibition in 1862, and a *Requiem Mass* for the funeral of Alessandro Manzoni in 1874. In place of the amorous, sentimental, and brilliant music of Bellini, Rossini, and others, Verdi has sought to substitute work of a manner type, characterized by energy and grandeur. During the Austrian rule in Italy he responded to the aspirations of his compatriots after liberty and gave musical expression to them, so that his name ("Viva Verdi") became their rallying-cry. In his later years he has lived with his second wife, Giuseppina Strepponi, a noted singer, in Genoa, and at his villa near Busseto, where he occupies himself with agriculture. In 1859 he was elected a member of the national assembly of Parma; in 1861 he became a member of the Italian chamber of deputies; in 1874 he was named by Victor Emmanuel a member of the senate. In 1859 he was chosen a corresponding member of the Paris Academy of Fine Arts, and in 1864 succeeded Meyerbeer as associate.

VERE, AUBREY DE. See DE VERE.

VERGENNES, CHARLES GRAVIER, COMTE DE (1717-1787), a French statesman, born at Dijon, Dec. 28, 1717, being son of the president of the parliament of Dijon. He early entered the French diplomatic service, and in 1740 accompanied the diplomat, M. de Chavigny, as a member of his staff to the court of Lisbon. In 1750 he was appointed minister at the court of the Elector of Treves, and, from 1755 to 1768, was ambassador to the court of the Sublime Porte. In 1771 he was sent to Sweden and had no small share in the revolution that occurred under Gustavus III. When Louis XVI. came to the French throne in 1774, he immediately recalled Vergennes from service abroad and made him his minister of foreign affairs, which office he filled with all the tact and ability of a skilled diplomatist, having ever before his eyes as his supreme object the interests of his king and country. Among the leading acts of his ministry were the treaty of Soleure, concluded with the Swiss in 1777, the treaty of Teschen with the Emperor Joseph II. in 1779, and the treaty of commerce negotiated with England in 1783. But still more important to Americans was the steady and efficient support lent by him to the United States in their struggle for independence. When disasters befell their arms in 1776 and commissioners were sent to various countries in Europe to seek foreign recognition and aid, he granted, in December, a courteous audience to Franklin, Deane, and Lee, and counselled the king to grant them money from the royal exchequer and permit them to purchase military supplies. In December, 1777, he encouraged Louis to recognize the independence of the States and to enter into a

treaty with them (signed February, 1778), through which they secured the co-operation of French land-forces and war-ships, as well as aid in money and munitions. Later he openly and in defiance of England presented Franklin and his associates at the court of Versailles, shortly after which M. Gerard was sent as minister plenipotentiary to the United States, while Dr. Franklin was received in the same character at the French court. When John Adams arrived in Europe in July, 1781, asking a seat in the congress of ministers about to be held at Vienna to treat of peace between Great Britain and all her enemies, Vergennes insisted on this being conceded him, and on the British refusal to recognize Adams he was instrumental in having the congress abandoned. Finally Comte de Vergennes was a party to the treaty of peace signed at Paris, Sept. 3, 1783, by which American independence was definitively recognized, though in arranging the terms he showed himself fully as favorable to Spain as to the United States. He died at Versailles, Feb. 13, 1787.

VERNE, JULES, French author, was born at Nantes, Feb. 8, 1814. He received his literary education in his native city, had some experience as a sailor, and afterwards studied law in Paris. In 1858 he made his debut in literature with a versified comedy, *Les Pailles Rompues*, and followed it up with a comedy in three acts, *Onze Jours de Siège*, and several comic operas. In 1863 appeared his *Cinq Semaines en Ballon*, a romance in which he weaves the results of modern scientific research into a fantastically imaginative narrative, indulging, at the same time, in adventurous flights of fancy into the region of the possible future of science, especially as relating to geography and astronomy. The immediate success of this production encouraged its author to work this vein and he gave forth an astonishing number of works in which plausible science and romantic exploits were grotesquely blended. Among them are *Les Aventures du Capitaine Haller*; *Le Voyage au Centre de la Terre*; *De la Terre à la Lune*; *Les Enfants du Capitaine Grant*; *Vingt Mille Lieux sous les Mers*; *Une Ville Flottante*; *Le Tour du Monde en quatre-vingt Jours*; *Le Pays des Fourrures*; *Le Docteur Ox*; *Michel Strogoff*; *Hector Servadac*; *Les Indes Noires*; *Un Capitaine de Quinze Ans*; *Les Cinq Cent Millions de la Begum*; *Les Tribulations d'un Chinois en Chine*. Most of these have been translated into English and widely popularized in dramatic versions, to which they readily lend themselves. But Verne has not confined himself to romantic fiction. He has compiled and edited *Géographie Illustrée de la France*, and *Histoire générale des grands Voyages et des grand Voyageurs*, the latter being also translated into English.

VERPLANCK, GULIAN CROMMELIN (1786-1870), scholar and statesman, was born in New York, Aug. 6, 1786, of mingled Dutch and Connecticut stock. His father, Daniel C. Verplanck (1761-1834), was a member of Congress, 1803-9; his mother's father was Dr. W. S. Johnson, President of Columbia College. Graduating there in 1801, he studied law and travelled in Europe for several years. Returning, he engaged in State politics, was a candidate of the Malcontents for the Legislature, and entered that body in 1820. His anniversary discourse before the New York Historical Society in 1818 on *Early European Friends of America* attracted much attention. Some satires on DeWitt Clinton were credited to Verplanck. Though a layman he was professor of Christian evidences in the Episcopal General Seminary, and in 1824 published *Essays on the Various Evidences of Revealed Religion*, in which he laid chief stress on internal or moral evidence, rather than the external or historic. His *Doctrine of Contracts* (1825) was praised by Wheaton. From 1825 to 1833 Verplanck was in Congress, where he worked for the extension of copyright, and Poe says that "While in Congress he was noted as the most industrious man in that assembly, and acted as a

walking register or volume of reference, ever at the service of his colleagues." In 1834 he was Whig candidate for mayor and was narrowly defeated. After that he sat for some time in the State Senate, and was active in its judicial functions. In 1833 appeared his *Discourses and Addresses*, and three volumes of *Miscellanies* reprinted from *The Talisman*, which he had conducted with Bryant and R. C. Sands. His reputation was enhanced by college addresses on *The Right Moral Influence and Use of Liberal Studies* at Geneva, 1833, on *The Influence of Moral Causes on Opinion, Science, and Literature*, at Amherst, 1834, and on *The Advantages and Disadvantages of the American Scholar*, at Union, 1836. He issued an annotated edition of Shakespeare (3 vols., 1844-47), but the plates were destroyed in the fire at Harper's, 1851. Verplanck's position in New York may be compared to that of Ticknor in Boston. (See TICKNOR in the *ENCYCLOPEDIA BRITANNICA*.) From 1829 he was vice-chancellor of the University of New York, and from 1846 president of the commissioners of emigration, and writing most of their reports. Much of his later years was spent in his ancestral home at Fishkill. He died in New York March 18, 1870, and Bryant delivered a memorial address before the Historical Society in May following.

VERRAZANO, GIOVANNI (c. 1480-1527), Italian navigator and explorer, is supposed to have been born shortly after 1480 in Florence, Italy, where members of his family had attained high office. He is said to have travelled extensively, particularly in Egypt and Asia, and is even doubtfully reported to have commanded one of Aubert's ships in that mariner's expedition from Dieppe to America in 1508. In 1521 Verrazano appears in history as a French corsair under the name of Juan Florin or Florentin, preying on the commerce of Spain with her new possessions. In particular he is said to have captured in 1522 the rich treasure-ship in which Cortez was sending to Charles V. of Spain the spoils of Mexico, valued at \$1,500,000. While following this occupation he seems to have attracted the notice of Francis I., King of France, under whose auspices he started in 1523 with 4 ships, professedly to reach Cathay by a westward voyage, "expecting to penetrate any intervening land," although it may be questioned whether his real object was not piracy as well as a desire to reach the new regions discovered by Cabot and Cortereal—that is, North America. His little fleet encountered violent storms and he was obliged to put back to some port in Brittany with only two vessels, in one of which, the *Dauphine*, he made a fresh start Jan. 17, 1524, from the Island of Madeira, with 50 men. In 50 days he made the land in N. lat. 34°, not far from Cape Fear in North Carolina, and began his search for a harbor by coasting 50 leagues to the south. Failing in this object, he turned along the shore northward, and while at anchor (perhaps near Raleigh Bay) sent a boat ashore for water and found the natives (whom he describes as black, of moderate stature and good proportions, and naked save for a breech-cloth) friendly and hospitable. Still following the shore, in fifty leagues he reached a pleasant place where he anchored, and found the natives fairer than those first seen and the country as fertile but colder. Hence his crew carried off a boy and brought him with them to France. After coursing a hundred leagues farther to the north-east, he arrived at a spot between small steep hills where a great stream poured its waters into the sea. Anchoring in the river, Verrazano sent his boat in, and this, after going half a league, found that the entrance widened into a lake of three leagues circuit, upon which at least 30 native boats were passing from shore to shore. A sudden squall frightened the boatmen and they returned to their ship without further exploring this pleasant harbor, which seems to have been that of New York. Sailing thence east, they then discovered about 10 leagues from the

mainland an island of triangular shape and "about the size of Rhodes," to which they gave the name of Louisa, mother of Francis I. From this island (supposed to be Block Island) Verrazano steered landward and in fifteen leagues came to a most beautiful harbor which he places in the parallel of Rome, 41° 40' N., when the natives in their boats crowded around the ship and showed themselves curious and friendly, being easily persuaded to come aboard. They are described as fine-looking, the handsomest seen on the voyage, of taller stature than Europeans, of light color, sharp faces with long black hair and black eyes, but with a mild expression. In this agreeable harbor, which has been identified as Newport, Verrazano tarried 15 days, and then, through the kindness of the inhabitants having supplied himself with all necessaries, he sailed for 150 leagues farther along the coast, the next landing being made in a country colder, full of thick woods, and where the natives were rude, shy of strangers, and clothed in skins. This landing has been placed not far from Portsmouth, N. H. Continuing the voyage hence, in a north-easterly direction, 52 islands were discovered, all near the shore, but without stopping to examine these Verrazano held on another 150 leagues, when he attained about latitude 50° N. Here, having reached the country already discovered by the adventurous fishermen of Brittany, and finding his stores almost exhausted, he decided to return to France, having, as he says, discovered more than 700 leagues of unknown territory. His arrival at Dieppe is placed early in July, 1524, for his letter to the king giving an account of his discoveries is dated from that port, July 8, 1524. We lose trace of Verrazano after his return from this voyage. It has been suggested that he went to England and offered his services to Henry VIII., and contemporary allusions give color to the suggestion. Biddle, in his *Memoirs of Sebastian Cabot*, suggests he was the Piedmontese pilot who was killed and eaten by the savages in Rut's expedition of 1527, which would harmonize Ramusio's statement that Verrazano made a second voyage to America and lost his life there. But Spanish official documents show that Juan Florin, with other French pirates, was captured at sea in 1527, and in November hanged at Colmenar, between Salamanca and Toledo. A letter is said to have been found, bearing date Paris, Nov. 14, 1527, which speaks of Verrazano as preparing an expedition of five ships for America. It is not possible, indeed, to reconcile the statements regarding him after his return from America. (J. H.)

VETO. During the colonial period in the history of this country, all legislative authority being ultimately in the crown and parliament of Great Britain, the veto power as now recognized had no existence; as all colonial legislation took effect under the assent of the British power, that specific limitation known as the veto power was merged in that which had a more universal nature. The people of the colonies naturally regarded with disfavor that which appeared to them to be an arbitrary interference with the right of popular government. With the assertion of the right of self-government by the colonies, the effect of this sentiment was not dissipated, and hence we find that the necessity for an executive veto was not readily recognized by them.

Massachusetts in her constitution of 1780 adopted the provisions that, with hardly any change of substance or form, have passed into the Constitution of the United States and of the States generally. These provisions required that the acts of legislation should be signed by the governor or that he should return them to the legislature with his objections, whereupon they could only take effect when passed by a two-thirds vote. Until the charter of 1726 the governor had an absolute veto upon the legislation.

Under the frame of government for Pennsylvania in

1682 and that of 1683 the governor had the initiation of measures of legislation, which was equivalent to an absolute veto, while under the charter of 1701 he had an absolute veto given in terms, of acts tending to change that organic law. By the constitution of 1790 the provision as to the veto was adopted in the form in which it had been adopted by Massachusetts in 1780, and this provision was continued in the constitution of 1838.

The Massachusetts clause was adopted in the constitution of New York in 1821, and was continued in the constitution of 1846. Connecticut adopted the provision in the same general form, but allowed a mere majority to overcome the veto in the constitution of 1818. Virginia did not embody such a clause in her constitution until 1870.

The executive veto of legislation may be regarded as a fixed part of our system of government, but reduced from an absolute negative of legislation to a check that may be overcome by the vote of a majority or a larger proportion of the legislative body. In most of the States two-thirds of the quorum is necessary, but in some a mere majority is sufficient.

At the present day the executive veto is recognized by the United States and all of the States except North Carolina, Ohio, Delaware, and Rhode Island. In every instance where the veto exists it may be overcome by a competent proportion of the legislative body. A vote of three-fifths is necessary for the purpose in Maryland and Nebraska. Two-thirds of the whole number elected is required for that purpose in Missouri. Two-thirds of a quorum is necessary in California, Colorado, Florida, Georgia, Illinois, Iowa, Kansas, Louisiana, Maine, Minnesota, Mississippi, Massachusetts, Nevada, New Hampshire, New York, Oregon, Pennsylvania, South Carolina, Texas, Virginia, and Wisconsin. A majority of all persons elected is required in Tennessee, West Virginia, Alabama, Arkansas, Indiana, Kentucky, and New Jersey. A majority of a quorum is required in Connecticut. In Vermont the vote is a merely suspensory act, subject to the action of the next session, and proceeds from the governor and council.

The Constitution of the United States provides that a bill presented to the President for his signature shall become a law unless returned in ten days, unless Congress by its adjournment prevents such return, and the States generally that have veto provisions have a similar clause varying as to the time within which the bill must be returned.

The Articles of Confederation did not provide for a veto, for that form of government did not admit of its application as an executive act, the States being represented in the system as sovereign communities. The Constitution of the United States followed the form originally adopted by Massachusetts requiring two-thirds to overcome the veto of the President. The discussion in the convention that framed the national Constitution exhibits differences of opinion on this subject, three plans being suggested—one for an absolute veto by the President, another proposed revision by the President and judiciary, and the third that which was finally adopted. The preponderating influence was in favor of a two-thirds vote. An attempt was made to confer a veto over laws of the States upon the Federal Government, but in its place power was conferred upon the federal judiciary to declare laws of States that were not in conformity with the Constitution of the United States of no effect. The question of vesting the veto power was discussed upon propositions to place the whole in the executive or partly in that officer and partly in the judiciary, but the final result was its being placed in the executive alone, qualified by the authority conferred on two-thirds of Congress to destroy its effect.

According to existing practice, the two-thirds of Congress competent to enact a law notwithstanding the President's veto is two-thirds of the number act-

ing as a quorum of the respective houses of Congress, and not two-thirds of the persons qualified to sit in those houses.

During the first half century under the Constitution the veto power was used for enforcing the executive views of the limitations of the Constitution upon the authority of Congress. The establishment of the Bank of the United States at the commencement of the government divided opinion on the question of its constitutionality, which culminated in the exercise of the veto power by Pres. Jackson to prevent the re-charter of that institution. Another subject of grave differences was the constitutionality of any attempt on the part of Congress to create and maintain internal improvements within the territory of the States. Both Madison and Jackson applied the veto to prevent the exercise by Congress of such power, which they regarded as infringing upon the sovereignties of the States, neither, as they regarded the matter, expressly conferred upon Congress nor necessary for the exercise of such as had been expressly conferred.

The frequent use by Pres. Jackson of the veto power produced a political reaction against its employment in the manner that was by many regarded as tending to suppress efforts for the development of the material resources of the country. The creation of internal improvements to connect together the great water-ways of the country, the magnitude and interstate relationships of which were regarded as rendering the action of the general government essential to their institution, gave prominence to the discussion of the question of the veto power.

Another interest that gave animation to the discussion was the growing opinion that the revenues of the country should to the largest extent be obtained from imposts, duties upon imported goods, as means of developing the material resources of the country. The rigid construction of the powers of Congress that was insisted upon by those who adhered to the school of strict construction of the Federal Constitution had found expression in the exercise of the veto power professedly for the vindication of the limitations imposed by the Constitution upon the powers of Congress.

Another subject that has induced the active exercise of the veto power was the interests connected with the institution of slavery, that culminated in the rebellion of 1861. The period of reconstruction that followed the close of this rebellion brought into conflict local and general interests, and the veto power was used by Pres. Johnson to enforce his views of the constitutional relations of the States to the Federal Government. Prior to the close of the period of reconstruction the absorbing political topic in the United States was the balance of power between the general government and the States, and the form in which the veto power was placed by the Constitution, and the mode of its subsequent exercise may be regarded as largely influenced by the pendency of that fundamental question. To reach a balance between national and local sovereignties that should give efficacy and unity to the national government without suppressing or impairing the efficiency of the States in the exercise and development of their internal powers and resources, was a problem that had neither upon theoretical or practical grounds been solved in the experience of mankind, and if, while engaging the profound thought of statesmen, it should happen to excite jealousy among those favoring the one or the other source of public authority, it ought not to be regarded with surprise.

While the question of the balance of power between the States and the national government must remain indefinitely subject at any time to produce animated discussion and contrarieties of opinion in the United States, still the occasion that gave the greatest interest to this discussion has passed with the abolition of slavery, which by dividing the country upon lines that expressed fundamental differences in their social and economic structure gave direct interest to every sug-

gestion that tended to weaken the national government as against the States.

The prominence of questions of constitutional authority in the vetoes that occurred in the early history of the country tended to associate that power specifically with questions of that character, and to create an opinion that it was improperly used where the occasion of its use was a difference between the executive and Congress as to the policy of public measures. The Constitution drew no such distinction, while it provided ample means for subjecting the action of Congress to the limitations imposed upon it by the Constitution, by conferring authority to uphold those limitations upon the national judiciary. The circumstance that the proper effect of the veto under the Constitution was to require Congress to act by a larger number than a mere majority in certain cases, points the conclusion that the object of the veto was to secure mature consideration in such cases, and that object would embrace questions of policy as well as those that involve constitutional powers. Viewed in this light, the constitutional veto may be regarded as a power placed in the hands of the executive, by which a more mature consideration may be required on the part of Congress than what is implied by its acting by a mere majority. Such executive authority does not contradict the principle of representative legislation, but only exacts a more full expression of the legislative mind in cases where differences exist between the opinions of the executive and the legislative departments of the government. The fact that the termination of a session of Congress before the expiration of the time allowed by the Constitution for the action of the President upon bills presented to him for his approval may, and often does, defeat legislative action, may be regarded as an accident of the system that is unavoidable, and not as impugning the principle that under no circumstances should the executive will prevail over that of the legislative body; although advantage may be taken of that fact to defeat legislative action, yet the result can only be ascribed to the abuse of a proper power which may not be dispensed with, although possible to be abused.

It is plainly inferrible from the nature of the executive office that the veto was not intended to interfere with matters of detail in legislation, for a minute inquiry on the part of the executive into the details of legislation would be inconsistent with the proper discharge of the executive duty that demands a general oversight of the interests of the government. As means of protecting the great interests of the country, its nature can be readily understood, for legislative bodies are likely, notwithstanding the checks and guards afforded by parliamentary organization, to act at times hastily and improvidently, especially under the influence of excitement arising from popular apprehensions of public evils, and for the vindication of the principles that sustain the administration of justice and a wise public policy, such means of securing deliberation can readily be understood. As parliamentary bodies are liable, notwithstanding the means of securing deliberation afforded by the experience of government, to act without due deliberation, it would seem necessary that some means should be devised for the protection of the important public interests in such an event, and the executive veto is the only means for that purpose that has been proved by the experience of government. (A. J. W.)

VICKSBURG, SIEGE OF. After the battle of Corinth, Oct. 3-4, 1862 (see CORINTH), Gen. Grant, in command of the department of the Tennessee, proposed to Gen. H. W. Halleck, then general-in-chief of all the national armies, a movement having as its objective the capture of Vicksburg. His views being approved, he, on Dec. 8, ordered Gen. Sherman to move down the Mississippi from Memphis with this ulterior object, while Grant himself should co-operate with him by land. The cap-

ture of his secondary base of supplies at Holly Springs, Dec. 20, and the difficulty of protecting the long line of communications, induced him to abandon the land expedition and take command in person of the movement down the Mississippi. On arriving at Milliken's Bend, 20 miles above Vicksburg, on the west side of the river, he found Sherman there, and directed him to attempt the capture of the strongly fortified position of Haines' Bluff, on the Yazoo River. Sherman crossed the Mississippi at the head of 32,000 troops, and ascended the Yazoo, landing immediately below the bluff. His assault was repulsed with severe loss, and Grant, establishing his head-quarters at Memphis, commenced preparations for co-operation with Sherman in a concentrated movement against Vicksburg. On Dec. 29, 1862, he arrived at the head of 50,000 men at Young's Point, nearly opposite the mouth of the Yazoo River, 3 miles above Vicksburg, Admiral Porter co-operating with a fleet of gun-boats carrying 280 guns and 800 men. Various modes presented themselves for reaching the high ground behind Vicksburg, whence only it could be assaulted. Three received especial consideration: (1) By crossing the river below Vicksburg and co-operating with Gen. Banks, who was ascending the river in command of an expedition from New Orleans; (2) By constructing a canal across the peninsula opposite Vicksburg for the passage of gun-boats and transports, and which would be kept open as a line of communication for supplies; (3) By turning the Mississippi out of its course and crossing its bed. Each of these plans, specious in theory, was found impracticable, mainly on account of the weather, the swollen condition of the river, and the state of the country. After spending about three months at Young's Point "trying," Gen. Grant says, "to get on high land and waiting for the river to recede," he determined to attempt a plan more hazardous than any of the others. This was to run the batteries of Vicksburg with his gun-boats and transports, march his troops down the west bank of the Mississippi from Milliken's Bend to a point in the neighborhood of New Carthage, and ferry them thence over to the east bank. The movement was begun March 29, when the troops set out on their march to New Carthage and Hard Times. On the night of April 16 the fleet ran the batteries of Vicksburg under a hot fire. On April 29 Gen. Grant reconnoitred Grand Gulf, and finding it too strong to promise success to an assault, ran its batteries with his gun-boats, etc., as he had done those of Vicksburg, to a point farther down the river. On the 30th the advance of his army was ferried across to the east bank at Brownsburg, 30 miles south of Vicksburg, and forthwith marched out in the direction of Port Gibson, near which, on May 1, it encountered Gen. Bowen at the head of some 7000 men, defeated him, and chased him for some miles. On May 3 the Big Black River was reached and also the Mississippi at Grand Gulf, at which place he made his head-quarters for a few days.

Grant now found himself between two hostile armies—one with head-quarters at Jackson, 45 miles east of Vicksburg (of which Gen. Joseph E. Johnston, sent as Confederate general-in-chief of the Vicksburg campaign, took the command on May 13), the other under Gen. J. C. Pemberton, with head-quarters at Vicksburg. With the view of relieving his front, Grant had ordered Sherman to make a feigned attack on Haines' Bluff, which compelled the Confederates to despatch troops to its relief. This feint had been successfully executed on April 30, whereupon Sherman marched to join the main army. Three days were spent in Grand Gulf in ferrying over Sherman's army and reconnoitring towards Vicksburg. By the evening of May 6 Sherman's corps had joined the main army in Grand Gulf, and it became Grant's policy to cut himself adrift from his base, and, by a rapid movement, to strike first the one and then the other of the hostile

armies ere they had time to unite. On May 7 the movement commenced, with the assault of Vicksburg from the rear as its ultimate object. On the 12th McPherson leading Grant's advance met at Raymond a force under Gen. Gregg from Jackson. This was defeated and driven back on that city. The next move was direct on Jackson, where Johnston now was at the head of 12,000 men, and on the 14th this place was taken, the supplies collected there destroyed, and the railroad bridge broken down. Johnston lost 845 men and 17 guns. Grant instantly faced to the west against Pemberton, met him on the 16th at Champion's Hill, and, after the hardest fought battle of the campaign, defeated him with a loss of 1400 put *hors de combat*, 2500 prisoners, and 24 guns. On the 17th the enemy was again encountered intrenched at Big Black River bridge, and, after a hard fight, driven across the river, with a heavy loss in killed and wounded, and of 1751 men captured as well as 18 guns. On May 18 the outworks of Vicksburg were reached, and the Confederates driven within the fortifications. The city was forthwith invested, and from this date the siege is to be reckoned.

Grant, believing Pemberton's troops demoralized by their defeats at Champion's Hill and Big Black, ordered a heavy assault on the 19th and another on the 22d. Both resulted in discomfiture, although some of the enemy's advanced positions were captured. On the 23d the siege was begun in regular form, and the troops set to work in fortifying the position and pushing it forward towards the enemy's parapets.

Vicksburg is situated on the east bank of the Mississippi, a mile below the junction of the Yazoo, and stands on an uneven bluff, much broken up on the land side with ravines, having an average height of from 200 to 250 feet above the river. Its defences commenced 3 miles below the town and followed the highest ridge in an east and north-east direction till they reached the Jackson Road, where they turned due north and then west for 2 miles till they reached the river at Fort Hill. The total length was about 7 miles. The line had been selected in the autumn of 1862, and most thoroughly fortified during the winter and spring. At an average distance of 200 yards batteries had been constructed, the parapets 25 feet thick, 10 feet high, and ditch 7 feet deep. The works were defended by 128 guns. In addition to land-defences, the circuit was made complete by a series of water-batteries stretching along the Mississippi from Fort Hill on the north to where they met the land-batteries on the south. These mounted 30 pieces siege artillery of the heaviest calibre and 13 pieces field artillery. The troops for the defence numbered over 20,000 effectives, in four divisions, under Gens. Stevenson, Forney, Smith, and Bowen, with the addition of Waul's legion. Stevenson held the right, Forney the centre, Smith the left. Bowen's division and Waul's legion were in reserve.

Grant had 71,000 troops to conduct the siege and defend his rear against Johnston, who had now been reinforced to over 30,000. By June 30 he had 220 military guns in position, all light field-pieces except 6 32-pounders, supplemented by a battery of heavy guns from the navy—in all 248 pieces. Sherman held the right of the besieging force, starting from the river; McPherson came next; McClelland stood left of him, holding the road south to Warrenton. Lauman's division, which arrived at this time, held the extreme left. Grant's head-quarters were at the north-east angle, where Sherman's and McPherson's corps touched. His whole line measured about 15 miles. A sap which had been run up to the enemy's parapet was exploded on the 25th June without any definite effect, and an attempt to charge after the explosion resulted in failure. On July 1 another mine was exploded, and destroyed a redan, killing and wounding a number of its occupants, but no attempt was made

to charge. From this time the work of mining and pushing the position nearer the enemy went on with renewed vigor. Already the approaches had reached the enemy's ditch, and orders were given to prepare for the assault on July 6. Meantime the garrison had begun to suffer from failure of supplies. An intercepted despatch had informed Grant that Johnston had planned an attack to relieve it, while Pemberton was to cut his way out. The line of defence which his reinforcements enabled Grant to make towards Jackson foiled this scheme, as the means taken by him in connection with Admiral Porter had on the 21st equally foiled a scheme of Pemberton's to leave the city for the Louisiana side by boats. When Pemberton saw that all hope of relief or escape had vanished, he, on July 1, addressed his four division commanders, asking whether they would counsel evacuation. Two directly counselled surrender; the other two did practically the same, saying that an attempt to evacuate would fail. Already Pemberton had received a message from Johnston suggesting he should negotiate for the release of the garrison with their arms.

On July 3 a white flag appeared on a portion of the works and hostilities along that line ceased. Shortly thereafter Gen. Bowen, and Pemberton's aide-de-camp, Col. Montgomery, appeared with a white flag and bearing a letter asking an armistice "for — hours" to allow commissioners to meet to arrange terms of capitulation. This Grant declined to accede to, but wrote, saying he would meet Pemberton to arrange for unconditional surrender of city and garrison, promising that the latter would be treated with all the respect due prisoners of war. At 3 P. M. Pemberton appeared with some of his officers and met Grant with some Union generals. Grant would accede to nothing but unconditional surrender, but agreed to send a letter embodying his final terms at 10 P. M. These terms—the surrender of the city and of the whole force, with their arms and munitions, as prisoners of war, not to serve again till properly exchanged—were accepted by Pemberton, and at 10 A. M., July 4, the Confederate troops marched out, each division taking position in front of its works, where it stacked arms, laying its colors upon them, and then marched back to the city. Logan's division marched in and took possession. Paroles were made out and signed as quickly as possible, the prisoners being meanwhile fed from the Union stores. On July 11 they marched out unarmed, and proceeded to the neighborhood of Enterprise, Miss., and Demopolis, Ala., where they remained till they were exchanged in the following September. The number of men actually paroled was 29,591, namely, 2166 officers and 27,425 men. There were also 790 who refused parole and were sent north as prisoners of war, so that the total force surrendered was, in round numbers, 30,400. The artillery found in the place numbered 172 pieces, 67 of which were siege-guns. Grant's total loss in the campaign (including expedition against Jackson) was a little under 10,000. Pemberton's loss, including men surrendered, has been estimated at 46,000. The total length of the siege, from May 18 to July 3, 1863, was 47 days.

The events of July 4, 1863, at Vicksburg and Gettysburg, sounded the death-knell of the Confederacy. The struggle was prolonged indeed, and maintained with the desperate resolution of brave men, but of men conscious that defeat awaited them in the end. Grant, for his brilliant services, was promoted to major-general in the regular army, and Congress, on its meeting, passed a vote of thanks to him and his army and voted him a gold medal. (J. H.)

VICTORIA, Queen of Great Britain and Ireland, and Empress of India, daughter and only child of Edward, Duke of Kent, was born at Kensington Palace, London, May 24, 1819, her mother being Victoria Mary Louisa, daughter of Francis, Duke of Saxe-Coburg-Saalfeld, and widow of Prince Charles of Leiningen. The Duke of Kent died when his daughter, Alexandrina

Victoria, was only eight months old, but her mother fulfilled the important duties devolved on her with admirable care and judgment. On Victoria's accession to the throne, on the demise of her uncle, King William IV., June 20, 1837, she was accomplished not only in the continental languages, drawing, music, and some of the sciences, but she was thoroughly instructed in the principles of the British Constitution. Retaining the late king's ministers, her first public act was to dissolve Parliament in person on July 17, reading her speech from the throne. Next year her coronation was celebrated, June 28, amid general rejoicing. Although but eighteen years of age at her accession, the dignity with which she bore herself, her strict propriety of conduct, and amiability of character won the hearts of her subjects, and she has retained their love and respect to the present day. On Feb. 10, 1840, she married her cousin, Prince Albert of Saxe-Coburg-Gotha, who proved not only a husband devoted to herself, but able and ready to further the welfare of her people. By him she has had nine children—four sons and five daughters—of whom seven still live. Her offspring are, the Princess Royal, Victoria, now Empress-Dowager of Germany, born Nov. 21, 1840, married Jan. 25, 1858, to Frederick William, then Crown Prince of Prussia, and later Emperor of Germany; Albert Edward, Prince of Wales, heir-apparent to the throne, born Nov. 9, 1841, who married March 10, 1863, Princess Alexandra of Denmark; Princess Alice, born April 25, 1843, married in 1862 to Prince Frederick of Hesse, died Dec. 14, 1878; Prince Alfred, Duke of Edinburgh, born in 1844, married, 1874, Marie Alexandrovna, only daughter of the Czar of Russia; Princess Helena, born 1846, married, 1866, Prince Christian of Schleswig-Holstein; Princess Louise, born 1848, married, 1871, the Marquis of Lorne, eldest son of the Duke of Argyll (the only child of the Queen who married a subject); Prince Arthur, Duke of Connaught, born 1850, married, 1879, Princess Louise of Prussia, daughter of Frederick Charles, the "Red Prince;" Leopold, Duke of Albany, born 1853, married, 1882, Princess Helen of Waldeck, died 1884; Princess Beatrice, born 1857, married, 1885, Prince Henry of Battenberg.

The leading events of Victoria's reign are here briefly noted. The year 1839 was marked by the turbulent proceedings of the Chartists. Their principles, which were embodied in "the five points of the charter," have since been largely recognized in legislation. In 1840 Sir Rowland Hill's penny-postage scheme was put in operation. The war against China, 1840-42, was closed by a peace, by which England secured a large war-indemnity, the island of Hong-Kong, and the opening of four ports in addition to Canton. In 1841 Sir Robert Peel came into power, and after great popular agitation, his administration repealed the corn-laws in 1846. Serious wars occurred in Afghanistan in 1842, and in the Scinde in 1843. In 1845 the great Sikh rising took place in India, which was not quelled till 1849. It resulted in the annexation of the Punjab. The famine in Ireland through the failure of the potato-crop in 1846 drove multitudes of its people from their homes to find an asylum in America. The widespread distress led to a revision of the poor-laws for the whole empire. In 1848, the year of European revolutions, the throne of Victoria alone stood secure, though there was an uprising in Ireland, and the Chartists gave some trouble in London. In 1849 Queen Victoria for the first time visited Ireland, and was received with demonstrations of loyal respect, while the name of the Cove of Cork, where she landed, was changed to Queenstown. On May 1, 1851, the World's Fair in Hyde Park, London, was opened by the Queen and Prince Albert, who had energetically promoted this industrial exhibition. In this year the first submarine telegraph cable was laid across the Straits of Dover. The close of 1852 was marked by the death of the Duke of Wellington, who had been the sponsor to

Ten years of peace were succeeded by new wars. In 1854 war with Russia led to the Crimean campaign by the united forces of England, France, Italy, and Turkey, and was closed by the capture of Sebastopol, Sept. 9, 1855. The formidable Indian mutiny burst forth in 1857 and was suppressed only after a long and desperate struggle. The great East India Company was abolished and its vast empire transferred to the crown of Britain. In this year the title of Prince Consort was conferred on the Queen's husband. A volunteer movement for the defence of England was inaugurated in 1859. The civil war in America caused much distress in England owing to the cotton famine. To Victoria the close of 1861 was darkened through the death of her devoted husband. Her grief was testified by many years of seclusion from the public. Besides architectural tributes to his memory, she caused the publication of his *Speeches and Addresses* (1862). Lieut.-Gen. Charles Grey prepared under her direction *The Early Years of H. R. H., the Prince Consort* (1867), and Sir Theodore Martin *The Life of H. R. H., the Prince Consort* (3 vols., 1875).

To resume our chronology: in 1866 telegraphic communication was established between Europe and America by the laying of the cable between Valentia, Ireland, and the coast of Newfoundland. Fenian troubles marked the year 1867. The same year was signalized by the passing of Disraeli's reform act, establishing household suffrage in boroughs and occupation franchise in counties, and by the formation of Canada into a dominion and the transference of the seat of government to Ottawa. In 1869 the Established Church of Ireland was disestablished and disendowed. This was followed, in 1870, by the passage of a land-act for Ireland, establishing courts for fixing reasonable rents. This has been the precursor of several kindred measures, down to the Ashbourne act of 1888, the general object being to restore peace to that unfortunate country. The purchase of commissions in the army was abolished in 1870. In this same year the elementary education act was passed for England and, in 1872, a kindred measure was passed for Scotland, education being now compulsory in both these countries.

At the close of 1871 the life of the Prince of Wales was for a time in imminent danger through typhoid fever. In 1871 the Emperor Napoleon III. found asylum with his wife and son at Chislehurst, Kent, where he died in 1873. In 1876 Parliament, at the instance of Disraeli, passed a royal title-bill, by which Victoria was made Empress of India. In 1877 that favorite minister of state was raised to the peerage with the title of Earl of Beaconsfield. In 1878, at the end of the war between Russia and Turkey, the island of Cyprus was ceded by the latter country to England. A war with the Zulus in South Africa, which broke out in 1879, was noted for the slaughter of the young Prince Napoleon, a volunteer with the British troops. Victoria erected a monument to his memory in Zululand.

Troubles in Ireland continued, and on May 6, 1882, Lord Frederick Cavendish and Mr. Burke were assassinated in the Phoenix Park, Dublin. Parliament then passed an Irish coercion bill of the most stringent nature, which still remains in force. For the war in Egypt in that year see ARABI PACHA. Lower Egypt was occupied by British troops and this led to complications with the fanatical Arab tribes of the Soudan, who, under the Mahdi, threatened Lower Egypt, slew Gen. Gordon, who had gone to Khartoum to pacify the region, and came in collision with the force which had been despatched too late for his relief. A bitter and undecisive "little war" was the result. One of its most prominent events was the battle of Suakim, in December, 1888, which resulted in the decisive repulse of the Arabs from that town.

In the early spring of 1884 died the Duke of Albany, who of all the Queen's children was said, in point of

tastes and culture, most to resemble his father. In December of this year Parliament passed an act by which practically the whole adult male population of Britain is enfranchised. Since then Parliament has been mainly occupied with Irish questions, the central one being that of Home-Rule.

In the spring of 1888 Queen Victoria visited Italy for the sake of her health and on her return journey spent three days in the month of April at the Schloss Charlottenburg, near Berlin, where her son-in-law, the Emperor Frederick, was to die on June 15. In the fall the Dowager-Empress came to her mother at Windsor.

A marked peculiarity of Queen Victoria has been her predilection for Scotland and its people, her favorite personal attendants, notably John Brown, being mainly of this nation. In 1847 she took up her first residence in the Highlands at the old castle of Ardenkie, Invernesshire, and since then her visits here have been, at least, annually. In 1852 Prince Albert acquired the fee-simple of the castle of Balmoral on the Dee, Aberdeenshire, with a property of 40,000 acres, largely deer-forest, and built a new castle on the site of the old one. Here, more than elsewhere, the Queen has ever since made her home proper, spending generally two months in autumn. In its neighborhood some private family monuments have been erected, and her dearest associations seem to cluster. Her majesty's literary productions are all associated with her Highland life, and tell of excursions amid the mountains and glens, of Highland sports, of her own home life, and of Highland life and usages.

Finally, her reign has been one of great activity, scientific, literary, and artistic, and books have multiplied in an unprecedented degree. The great names in these departments will be found under their separate entries. Victoria's name, like those of her predecessors, Elizabeth and Anne, marks an illustrious era in literature. (J. H.)

VINCENT, JOHN HEYL, bishop in the Methodist Episcopal Church, was born at Tuscaloosa, Ala., Feb. 23, 1832. He received an academical training, and entered the Methodist ministry. He has had charge of churches in New Jersey, at Newark, Franklin, and Irvington, 1852 to 1856; in Illinois, at Joliet, Mt. Morris, Galena, Rockford, and Chicago, from 1857 to 1865. He was made Sunday-school agent in 1866, and corresponding secretary of the Methodist Sunday-school Union in 1868. While engaged in active promotion of the cause of Sunday-schools he became convinced of the need of popularizing higher instruction in this country. Young men and women eager to be taught lacked opportunities to procure the training to which they aspired. The problem then was to diffuse liberal culture above the range of the common schools. By the generous aid of Mr. Lewis Miller Dr. Vincent was enabled in 1874 to put in practice at Chautauqua certain ideas which had been developed in his mind. The result has been partly described under CHAUTAUQUA, but the work has advanced to greater perfection since that article was published. Dr. Vincent was the superintendent of instruction there until 1884, and has since been chancellor of Chautauqua University. In 1888 he was chosen bishop by the General Conference. He has published *The Chautauqua Movement* (1886), *The Home Book* (1886), and manuals relating to Sunday-schools.

VINTON, ALEXANDER HAMILTON (1807-1881), clergyman, was born at Providence, R. I., May 2, 1807. His father, David Vinton (1774-1830), was a prominent merchant. Alexander, after spending three years at Brown University, studied medicine, and practised at Pomfret, Conn., but in 1833 abandoned medicine for theology. After studying at the Episcopal General Seminary in New York, he was ordained deacon in 1835 and priest in 1836. He was successively rector of Grace Church, Providence, 1836-42, St. Paul's, Boston, 1842-58, Holy Trinity, Philadelphia,

1858-61, St. Mark's, New York, 1861-70, Emmanuel, Boston, 1870-77. He then retired to Pomfret, but afterwards was professor of systematic divinity in the theological school at Cambridge. He declined the bishopric of Texas in 1857, and was candidate in other dioceses, but was not elected. With a noble voice and presence, he was impressive alike as preacher and pastor, and has been pronounced one of the greatest men of the Episcopal Church. He died at Philadelphia, April 26, 1881. His only publications were *Sermons* (1855).

His brother, FRANCIS VINTON (1809-1872), was born Aug. 29, 1809, graduated at West Point in 1830, and published *Arthur Tremaine, or Cadet Life* (1830). He served on topographical and engineer duty till 1836, when he resigned, having managed to study law at Harvard and be admitted to the bar at Portsmouth, N. H. But like his brother he turned to theology, entered the same seminary, and was ordained deacon in 1838, and priest in 1839. He became rector of St. Stephen's, Providence; of Trinity, Newport, 1840; of Emmanuel, Brooklyn, 1844; of Grace, Brooklyn, 1847. He declined the bishopric of Indiana in 1849, and in 1855 became an assistant minister of Trinity, New York, with charge of St. Paul's. In 1869 he was made professor of ecclesiastical law and polity in the General Seminary. He published *Lectures on the Evidences of Christianity* (1865), and *Commentary on the Canon Laws* (1870). He was a leader of the High Church party, as his brother Alexander of the conservative evangelicals. He died in Brooklyn, Sept. 29, 1872.

VIOLET, the common name of the genus *Viola*, the type of the botanical order *Vio-*
See Vol. XXIV. laceæ. The genus is a large one, p. 241 (p. 250 comprising about 200 recorded Am. Rep.). species of herbaceous, perennial (rarely annual) plants, the most of which are favorites of flower lovers. They possess short rhizomes or underground stems, alternate leaves, and solitary flowers, nodding or declined. The flowers have nearly equal sepals, produced at the base into a free appendage; the petals are unequal, the lower one produced into a sac or spur at the base.

Of the American species, *V. cucullata*, the common blue violet, is much the best known, and is found throughout the country. Other common species are *V. palmata*, the hand-leaf violet; and *V. pedata*, the birds-foot violet, a species with large and handsome flowers of blue or purple color; the two upper petals sometimes deep violet and velvety like the pansy. In addition to the blue, there are several species of white and yellow violets. Of the latter may be named *V. rotundifolia* and *V. pubescens*, the latter a fine, tall species, with an aerial stem 6 to 12 inches high. It bears yellow flowers, with striated petals, and thrives well under culture. Of the white species may be named *V. blanda*, the small scented violet, its flowers being white, small, and with a faint sweet perfume. It grows in wet meadows in company with another white-flowered species, *V. lanceolata*, the lance-leaved violet.

There are representatives of a second genus in the Northern United States, *Solea*, the green violet. *S. concolor* occurs from New York to Illinois and southward. It is a homely little plant, with small, greenish-white flowers, and has the power, in common with many other violets, of projecting its seeds to a considerable distance from the plant.

Europe possesses many beautiful species of violets, the favorite among them all being *V. odorata*, the sweet-scented violet. This is a low, creeping plant, the flower generally blue, but occasionally of other colors, and with a very delicate fragrance, much superior to that of any American violet. It has been naturalized here to some small extent. *V. tricolor*, a pretty little plant, is the source of all our cultivated varieties of pansies, heartsense, etc. Most of the cultivated vio-

lets are of Old World species, the American violets generally being not showy in culture, though *V. pedata* responds well to cultivation, and is becoming common in gardens. (C. M.)

VIOLET LE DUC, EUGENE EMANUEL (1814-1878), a French architect and author, was born at Paris, Jan. 27, 1814. He studied architecture, at first under Leclerc, occupying himself specially with the Gothic architecture of the middle ages, and thereafter by observation in the course of tours of investigation in Italy, Sicily, and Southern France, wherein he paid attention chiefly to Greek and Roman remains. In 1840 he was made inspector of the restoration of the Sainte Chapelle, Paris, and was successively intrusted with the restoration of the ancient churches of Verzeilay, of Saint Père, Montreale (Yonne), Poissy, Carcasone, and Semur; and of the Hôtels de Ville of Saint Antoine and Narbonne; and in 1845 with the restoration of the Church of Notre Dame, Paris. His success here led to his appointment as architect of the Abbey of St. Denis. In 1849 he restored the fortifications of Carcasone and superintended the embellishment of the Cathedral of Amiens. In 1853 he was appointed one of the three government inspectors-generals of religious edifices, in which capacity he conducted the restoration, among others, of the Church of Notre Dame, Chalons sur Marne; of the Cathedral of Laon, and of the Chateau Pierrefonds. In 1863 he was named professor of art, history, and aesthetics in the reorganized School of Fine Arts, but soon resigned. During the siege of Paris, 1870-71, he aided as an architectural engineer in the defence of his native city, and was lieutenant-colonel. Meanwhile his republican and free-thinking views, expounded through the press, raised a clamor against him. He was, however, charged with the construction of the Protestant Cathedral of Lausanne, Switzerland, and the restoration, for the Comte de Paris, of the Chateau d'Eu. But, owing to clerical opposition in 1874, he resigned his position as inspector of diocesan edifices and ceased to be architect of the Cathedrals of Rheims, Amiens, Clermont, and Paris, though retaining the office of architect of St. Denis. In 1874 he was elected to the Chamber of Deputies as republican candidate for Montmartre. It was on his report as a member of the Commission on International Expositions that the project of the palace of the Champs de Mars and the Trocadero united by a gallery was adopted for the Paris exposition of 1878. He latterly occupied himself with questions of the fine arts, and, among other things, proposed to multiply the statues of great men in Paris, and advocated the use of the Phrygian bonnet for the statues of Liberty. He died suddenly at his country-house, near Lausanne, Sept. 17, 1879. Among his publications are *Dictionnaire raisonné de l'architecture française de XI.-XVI. Siècle* (Paris, 1854-1868, 10 vols.; a twice-crowned *chef d'œuvre*); *Dictionnaire raisonné du mobilier Français de l'Époque carlovingienne à la Renaissance* (1854-1875); *Lettres sur la Sicile* (1860); *Entretiens sur l'Architecture* (1858-1872); *Cités et ruines Américaines* (1862-63); *Chapelles de Notre Dame de Paris* (1869); *Habitations modernes* (1874-75); *Histoire de l'habitation humaine* (1875); *L'Art russe* (1877).

VIRCHOW, RUDOLF, German pathologist and publicist, was born Oct. 13, 1821, at Schivelbein, Pomerania. In 1843 he graduated in medicine from the University of Berlin, and began to lecture on anatomy, being also prosecutor of the Charité hospital. In 1847 he established in Berlin, in conjunction with Reinhardt, the *Archiv für pathologische Anatomie und Physiologie und für Klinische Medizin* (from vol. xxi. by Virchow alone). This periodical, now having over 80 volumes, is recognized as one of the most authoritative in the world. In 1847 Virchow, in connection with Leubuscher, founded also the *Medical Reform*. In 1848 he was deputed by the government to investigate the nature of the typhoid epidemic in upper

Silesia, and his report took high rank in sanitary science. Aroused by the Revolution of 1848 he entered the political arena as a liberal leader, and was elected to the Prussian House of Deputies, but was declared ineligible on account of his age. His liberal politics also served to deprive him in 1849 of his lectureship, whereupon he accepted a call to the chair of pathological anatomy in the University of Würzburg, where he obtained fame by his lectures on cellular pathology. In 1852 he investigated, by request of the Bavarian government, the famine in Spessart; and in 1859, at request of the Swedish government, he investigated in Sweden and Norway the causes of leprosy. In 1856 he was recalled by the University of Berlin to assume the chair of pathological anatomy and to become director of the Pathological Institute, which he soon raised to the first rank among such establishments. Since 1859 he has, as a member of the city council of Berlin, devoted great attention to matters of sanitary science. Since 1862, as member of the Prussian House of Deputies, he has consistently opposed Bismarck's arbitrary policy, the governmental centralization, and the military domination. Though he had objected to the constitutionality of the creation of the German Empire in 1880 he entered the Reichstag, where he soon became famous by his coinage of the watchword "*Kulturkampf*." In the wars of 1866 and 1870 Prof. Virchow was director of the German hospital service. In 1869 he helped to organize the German Archæological Society at Innsbruck, and became a leader in the Berlin Anthropological Society. In 1873 he was chosen a member of the Academy of Sciences. As one of the instructors to the Berlin Workingmen's Union he actively engaged in popularizing science. In 1872, a German society having requested his withdrawal from the French scientific societies, he declined, saying a rupture of the scientific relations between the two countries would be contrary to the interests of civilization, of science, and of humanity. In 1879 he rendered some assistance to Dr. Schliemann, in the Troad, and he contributed the *Preface* and some appendices to his *Ilios* (1881), and two appendices to his *Troja* (1884). The cancerous disease that carried off Frederick III. in 1888 brought Virchow prominently before the world as the ultimate authority on the pathological problem. It has become evident also that he exerted a great political influence (in conjunction with Geffcken and others) upon the liberal-minded but unfortunate emperor.

In Germany, until the time of Virchow (1847), the basic principles of medicine were *a priori* assumptions. He claimed that facts and experiments were the only admissible foundations for that science, no matter how long it would take to collect them or establish them. "Observations and experimentation only have permanent value; they will prove the fortress of scientific medicine, the outworks of which are pathological anatomy and clinical research." Schleiden had discovered the cell to be the fundamental basis of the vegetable tissues, and Schwann had found it to be the basis also of the animal tissues. A few geniuses, from Vesalius and Paracelsus down to Virchow, had slowly and gradually shaped the theory of diseases as local anomalies. It remained for him, after a series of observations and experiments, to proclaim his cellular pathology as a consistent carrying out of the theory. He announced the necessity of localizing disease in the smallest composing element, or the cell. Therapeutics, under the guidance of experimental methods, have undergone important changes in the light of this theory, and have become vastly more efficient and local in application. Thus far every new discovery of pathological facts has found a ready explanation by the cellular theory and its methods, and the largest proportion of recent progress in pathology has been owing, directly or indirectly, to the adoption of his doctrine of cell-growth. Important in its influ-

ence on biology generally, it has little less than revolutionized pathological study. Under this view diseases of the different organs which, until their essential elements were demonstrated, appeared to have nothing in common, are now seen to be results of the same process. Thus a strong tendency may be observed at work toward the classification and unification of disease and the resolution of complex forms into the simplest elements. In other words, all the elementary processes of pathology may be seen in the different tissues and organs producing the same effects, though the effects are manifested in a manner peculiar to each part. With the same fundamental lesion the disease is the same essentially, although wholly distinct in appearance. Since the great bulk of disease can be resolved into these fundamental processes, a scientific and durable foundation for pathology is established which is of the highest value and significance for philosophic medicine. "The search," says Prof. Huxley, "for the explanation of diseased states in modified cell life; the discovery of the part played by parasitic organisms in the etiology of disease; the elucidation of the action of medicaments by the methods and the data of experimental physiology appear to be the greatest steps which have ever been made toward the establishment of medicine on a scientific basis." (See PATHOLOGY in the *ENCYCLOPÆDIA BRITANNICA*.)

In the course (1854-56) of his researches on vegetable parasites as among the causes of disease, Virchow invented the term *mycosis*, which has since been generally adopted. In the "Movement in Favor of Unity in Scientific Medicine" (in *Collection of Contributions to Scientific Medicine*, 1849) he spoke of the origin of life as a mechanical necessity, and in his three orations on *Life and Disease* (1862) he pointed to the transmutability of species as a necessary basis for the mechanical theory of life. He opposed the idea of Haeckel, that theories of natural selection should be taught in the public elementary schools, on the ground that facts only, and not theories, should have place there. The burden of his lecture at Munich, Sept. 22, 1877, is throughout a caution against evading the distinction between the problematical and the proven; "they are not on the same evidential level." He would teach, he said, "evolution, if it were only proved; it is, as yet, in the hypothetical stage; the audience ought to be warned that the speculative is only possible, not actual truth; that it belongs to the region of belief, and not to that of demonstration. As long as a problem continues in the speculative stage it would be mischievous to teach it in our schools. We ought not to represent our conjecture as a certainty nor our hypothesis as a doctrine." His principal works are: *Cellular Pathology* (4th ed., 1871); *Handbuch der Specieellen Pathologie und Therapie* (3 vols., Erlangen, 1854-62); *Pathology of Tumors* (3 vols., 1863-67), the most exhaustive and comprehensive work on that subject; *Die Entwicklung der Schädel-grundes* (Berlin, 1857); *Darstellung von der Lehre der Trichinen* (1866); *Treatises connected with State Medicine* (2 vols., 1879). He has also published: *Popular Lectures: Archaeological, Ethnological, etc.* (1866, sqq.); *Goethe as a Naturalist* (1861); *Aufgabe der deutschen Turnerer* (1864); *National Development and the Importance of the Natural Sciences* (1865); *Education of Women for their Vocation* (1865); *Hunger Typhus* (1868); *Severage and Drainage* (1869); *Problems of the Natural Sciences in the New National Life of Germany* (1871); *Die altnordischen Schädel zu Kopenhagen* (1871); *Ueber die Chlorose, etc.* (1872); *Technique of Dissection* (1876); *Liberty of Science in the Modern State* (1877); *Ueber die Weddas von Ceylon* (1881). Those whose titles are given in English have been translated into that language. (J. W. W.)

VIRGINIA CREEPER, the common name of a favorite American climbing plant, of the *Vitaceæ* or vine family, genus *Ampeloxis*, species *A. quinquefolia*, which occurs abundantly throughout the Atlantic

States, and extends as far west as Colorado. It is distinguished by a slightly 5-toothed calyx; the petals concave, thick, and expanding before they fall; the flowers in cymose clusters; the leaves digitate, with 5 oblong, lanceolate leaflets; the climbing tendrils digitate at end, and fixing themselves by dilated sucker-like disks at the tips. This is a common vine, growing in low or rich grounds, and climbing extensively, similar in habit and locality to the poison ivy or sumach, but easily distinguishable by its five leaflets, the poison ivy having but three. It blossoms in July, and ripens its small, dark blue berries in October, these forming an open grape-like cluster. At all periods it is an attractive feature of our woodland scenery, but particularly so in the autumn, when the leaves turn a bright crimson, and it stands out in rich contrast to the darker foliage of the trees to whose summits it has climbed.

(C. M.)

VITICULTURE. The culture of the vine, or grape plant *Vitis*, is one of the oldest of field industries, and may be traced back to a very remote period in the history of mankind. The use of wine as a beverage is mentioned in the earliest literature of China and India, Egypt and Palestine, and was very prevalent in the great kingdoms of later antiquity. It was eventually prohibited by law in China and the vines ordered to be torn up, while the precepts of Mohammed put an end to wine-drinking among the vast multitudes of his followers, but in Europe it has continued without intermission, and the culture of the vine is one of the most important agricultural industries of Southern Europe at the present day. All the varieties of the European vine are supposed to belong to a single species, *Vitis vinifera*. In American vine culture, on the contrary, this species is only generally grown in California, native species being the basis of the culture in the Eastern States.

The vine was early discovered to be a native of America, the Norse discoverers calling the country Vinland, from the abundance of grapes which they found. It was not, however, until recent years that any definite effort to cultivate the native grape was made. Wine is said to have been made from the European grape in Florida as early as 1564, while in 1602 it is stated that there were about 2,000,000 vines in Paraguay. Vines were planted in Virginia about 1620, at a later date in Delaware, and in 1683 by William Penn. in Pennsylvania. Many subsequent efforts to introduce the European vine were made, but were all unsuccessful, either the severity of the climate or the great susceptibility of this species to the attacks of insect enemies preventing its growth. Experiments with native species were not made until somewhat late in the present century. In 1835 Major Adlum, of Georgetown, D. C., brought the Catawba variety to notice. Its culture was ardently taken up by Nicholas Longworth, of Cincinnati, and with such success that by 1867 there were 2000 acres planted near that city. The lack of hardiness of the Catawba caused the development of other varieties—the Concord, Norton's Virginia, and others—and the total American acreage in vines in 1867 was about 2,000,000. (For the native species of American vines, and the principal varieties, see GRAPE.)

On the Pacific *Vitis vinifera* was introduced by Spanish Franciscans about 1771. After California became part of the United States and the gold fever had subsided, agriculturists began the culture of the mission grape, the vines which they found about the old mission stations, encouraged by the fact that these would grow without irrigation. But the wine made from their fruit proved of poor quality, and other varieties of the European grape, and recently of the American grape, were introduced, with much improvement to the wine product.

In Europe the cultivation of the vine, except under glass, has its extreme northern limit near Berlin, 52° 30' N. lat.; its southern limit at 26° S. Palatable wines,

however, can be made only in a much narrower district, the chief wine-producing countries being France, Spain, Portugal, Germany (valley of the Rhine), Austria, and Italy. In North America the hardy native vines thrive as far north as Massachusetts, but wine cannot be profitably made above Southern New York, Pennsylvania, and Northern Ohio. The culture of the vine has hitherto not been extensively prosecuted in the Southern States, though it is probable that good wines could be produced throughout that region.

In viticulture soil and location have a great influence on the quality of the product, often from causes that are not apparent. A southern slope is important for the profitable growth of the vine, and light soils are best, even sandy loams, but mineral food, especially potash, is necessary, and the best European soil seems to be that arising from the disintegration of felspathic and volcanic rocks. American vines, on the contrary, seem to prefer calcareous soils. The soil needs to be deep and well drained, "wet feet" being generally thought injurious to the vine. There are several methods of propagation, as cutting, layering, and grafting, and seed planting to produce new varieties. Grapes vary readily from seed growth. Seeds from black varieties like the Concord, for instance, will occasionally yield pure white or greenish varieties without cross fertilization, though the latter is considered the most advantageous process. The seeds need to be obtained from fully ripe fruit, mixed with sand and kept moist until spring, when they are sown in boxes under glass or in the open ground, being covered with a half inch of soil. The seeds of hardy varieties do best if kept where they will freeze during the winter. The seedlings are set out when a year old and trained to a single stake until they produce fruit. After the grapes appear the inferior vines are destroyed, and those worthy of preservation propagated in the usual methods. It is very rarely that an improved variety appears, the chance of success not being one in a thousand, though there is still much room for improvement in our native grapes.

The most common method of grape culture is by cuttings. These are taken from the previous year's growth, 3 buds being usually left, though single bud-cuttings with 1 or 2 inches of cane are used in propagating rare varieties. The latter need to be grown with great care, and are usually started under glass during the winter. Another common method is by layering. The layer is but a cutting left attached to the parent vine and fed by it until it has developed roots of its own. The principal advantage of this method is that certain varieties which are not readily propagated by cuttings may be made to produce roots on layers, the vitality of the planted canes being longer preserved. Grafting is a very ancient method. It was much practised in Roman times, and is frequently described in Latin treatises on agriculture. Its principal advantage is in giving hardy root stocks to delicate varieties. The most usual method is to insert the scion in the crown of the plant below the surface of the ground. It needs to be tied in and the earth banked around it, this serving instead of the wax employed in aerial grafting. It is necessary, however, to prevent the scion from sending out roots of its own, and its rootlets need to be removed several times during the season.

There are various ideas about the best methods of growing the grape. The open trellis and frame training is most common in the United States. In Europe, where wood is less abundant, single stakes are often used, the vine being pruned more severely than the American species will bear. The several diseases and insect enemies to which the vine is subject are described under GRAPE and PHYLLOXERA. The products of the vine are six in number: the fruit, which is largely used in the fresh state as an article of food; the dried fruit, or raisin, for which the sweeter grapes are used; the currant, which is the dried product of a

small seedless grape cultivated in the Levant; wine, the fermented juice of the grape; brandy, the alcoholic spirit distilled from wine; and tartar (the acid tartrate of potassium), which is deposited as a solid incrustation on the interior of casks in which wine is stored, and which, in its purified state, forms the cream of tartar of commerce.

Of these several products the American industry is confined to three only: the fruit, wine, and raisins. Grapes are grown very largely for table use, and the methods by which they can be kept in a fresh state until far into the winter add considerably to their consumption. Of recent years raisins, which were formerly produced only in Calabria, Sicily, and Turkey, have been successfully dried in California. (See WINES.) (C. M.)

VOGÜÉ, CHARLES JEAN MELCHIOR, MARQUIS DE, French archaeologist and diplomatist, was born at Paris in 1829. His father, Léonore, Marquis de Vogüé (1805-1877), was in early life a lieutenant of cavalry, but after the revolution of 1830 devoted himself to agriculture and iron-works until 1848, when he took part in forming the republic and supported the presidency of Louis Napoleon. But when the latter declared himself emperor Marquis de Vogüé again withdrew from public life, until 1871, when he was elected to the National Assembly and supported the monarchists. In 1853 his son, then Comte de Vogüé, set out for the east, where he devoted two years to exploring in Syria and Palestine. After returning to Paris he published several works of so high value that he was named a free member of the Academy of Inscriptions and Belles Lettres to fill the place left vacant by the Duc de Luynes. In 1871 M. Thiers named him ambassador to Constantinople, which office he held till 1875, when he was called to the embassy at Vienna. These positions, however, he owed rather to his fame as a scholar than to diplomatic ability, and on the accession of Pres. Grévy, in 1879, De Vogüé returned to France. He is author of the following valuable and handsomely illustrated works: *Les Églises de la Terre Sainte*, with 59 engravings (1859); *Inscriptions hébraïques de Jerusalem* (1864); a monograph on *Le Temple de Jerusalem*, with 50 plates, followed by an *Essai sur la Topographie de la Ville Sainte* (1865); *L'Architecture civile et religieuse du 1er au VIIe Siècle dans la Syrie Centrale*, with plates (1865-77); *Mélanges d'Archéologie Orientale* (1869); *Inscriptions Sémitiques*, 43 plates (1869-77). De Vogüé also edited the Duc de Luynes' posthumous work on the exploration of the Dead Sea.

VOLAPÜK, the "world language," invented by Johann Martin Schleyer, a Catholic priest, who was born at Oberland, Baden, in 1831, and at present resides in Switzerland. He became an ardent student of philology, and gained some knowledge of about 50 languages and dialects. His studies in this direction were largely devoted to the formation of a language which would be suitable as a medium of international intercourse, and in 1878 he published an outline of such a language, of which he issued a grammar and dictionary in 1880. He has since published numerous works on the subject; his system has been warmly welcomed in Germany and has attracted so much attention elsewhere as to call for a descriptive mention.

The idea of a world language is not new. Efforts have been made from time to time in this direction, the earliest being that of John Wilkins, Bishop of Chester, in 1668. There have been many later schemes proposed, recent ones being the "Ideography" of Sinibaldo de Mos in 1863, and the "Alevato" of Stephen Pearl Andrews in 1877. All these, however, were based on metaphysical or other impractical conceptions, and have no value other than as literary curiosities. Schleyer's scheme was the first of a practical character. Recognizing that all existing languages have irregularities of grammar, orthography,

etc., which render them troublesome even to natives and occasionally unlearnable to foreigners, it was his object to produce a language prepared solely with a view to its practical utility, in which the irregularities and complexities of existing languages should be avoided and complete simplicity and regularity be gained. Unfortunately his native language was German, and he has retained Germanisms of grammar and orthography which make his method difficult to other modern nations. Before giving the criticisms of linguists, however, we shall briefly describe the leading features of Volapük, this title signifying "world language" in the new method of speech.

Volapük possesses in all 37 letters. To the 5 pure vowels are added the German ä, ö, ü, sounds which very few persons of English, Spanish, or Italian birth are capable of properly making. The consonants, as he arranges them, are b, p; d, t; v, f; h, y, g, k; l, r, m, n; s, j, c, x, z. To these are added 10 new signs, invented or borrowed from existing alphabets, to supply deficient sounds. There are no diphthongs, the vowels have the Continental sounds, and certain of the consonants have arbitrary sounds, c being like j in joy, j like English sh. Thus *jip* is pronounced "sheep."

In forming the vocabulary a basic series of radicals or roots was chosen, these being mostly monosyllabic, with an internal vowel, and one, sometimes two, preliminary and final consonants. Dissyllabic roots are formed on the same principle. The root word is always a noun, concrete or abstract. English being recognized as the most important and widespread language of modern civilization, the roots are taken from it, wherever a suitable one can be found, other languages being used more sparingly. Thus English "man" forms an unobjectionable root. But English "house" is not in accordance with the rule of root formations. So Latin "dom" is chosen instead. "Sheep" is *jip*. Here the pronunciation is preserved, the spelling changed. It is necessary that all roots should begin and end with a consonant, in order that prefixes and suffixes can be readily added as grammatical inflections. The prefixes used are frequently ordinary or abbreviated prepositions. Some are adjectives or shortened nouns of quality. For suffixes *el*, *ik*, *am* are very commonly used. *El* forms nouns which indicate the doer. *Ik* is the termination of all adjectives but the numerals. *Am* corresponds to the English termination "ing" or "tion." *O*, *ü*, and *ö* are used as inflectional terminations. *O* forms adverbs; *ü*, prepositions; *ö*, interjections.

The grammar of Volapük has the modifications of Aryan grammar generally, and forms all these modifications by inflectional expedients. The plural is invariably formed by the addition of *s*, and tenses are formed from units in the same manner. The personal pronoun forms its genders in the third person by the addition of *om*, *of*, and *os*. *Os*, however, is not neuter; all things are masculine; *os* is used only impersonally and abstractly, as *totos*, "it thunders." In nouns denoting person the suffix *ji* makes the noun feminine. In animals *om* denotes the male, *ji* the female. The nominative case is the simple word form. To form the genitive, dative, and accusative *a*, *e*, and *i* are added; in the plural *as*, *es*, and *is*. The preposition governs the nominative except when it denotes motion, then the accusative. Adjectives and participles may be declined when separated from the nouns which they qualify, so that the relation can be shown. The personal pronouns are *ob*, "I"; *ol*, "thou"; *om*, *of*, *os*, "he, she, it"; *on*, "one," or "they," as in "they say." These are attached to the roots to form the person endings of verbs in the indicative, as *penob*, "I write"; *penol*, "thou writest"; *penon*, "one writes"; *penobis*, "we write," etc. The signs for the tenses are prefixed vowels, *a* for the present; *ä*, imperfect; *e*, perfect; *i*, pluperfect; *o*, future; *u*, future perfect. Example: *äpenob*, "I wrote"; *epenol*, "thou hast

written." The prefix *p* before the tense vowel makes the verb passive, as *patibof*, "I am loved." The conditional and subjunctive moods are indicated by the addition of a syllable, *öv* and *lu* respectively, after the person ending, thus: *äbinoböo lubik*, if *abinobla liegik*, signifies "I would be happy if I were rich." The imperative adds *öd* to the person ending, as *golölöd*, "go thou." The infinitive ends in *ön*, the participle in *öl*, while other prefixes, suffixes, and infixes are employed to cover other exigencies of grammatical inflection.

In forming sentences the words are arranged in the following order: First, the subject; second, the predicate; third, the object. Each principal word is followed by its modifiers, except that adverbs, when modifying adjectives or other adverbs, precede. The negative *no* also precedes the negated verb. This arrangement is a radical departure from the German method, in which the verb is placed at the end of the sentence.

Volapük has grown with some rapidity into favor. It made some progress in Germany and Austria previous to 1884, in which year it was taken up in Holland and Belgium, and in France in 1885. It was introduced into the latter country by Dr. Kerekhoffs, who made several changes; the most of which were decided improvements. Other European nations became interested in it during 1885 and 1886, but little interest was shown in England and in the United States until 1887, since which time much has been written on the subject, text-books published, and classes formed in several cities, though principally among persons of German birth. A convention was held in Munich in August, 1887, the delegates being mostly Germans. At this several simplifications were adopted, a general society of Volapük clubs formed, and an academy established, which began its functions in 1888. Father Schleyer is at the head of both these organizations. Over 100 books on the subject were published in Europe up to July, 1887, and many more have been issued since. Several periodicals in Volapük are now published, and the number of persons who have studied it is given at 100,000. It has been brought into considerable use in commercial intercourse, and has in fact made a remarkable progress, indicating the need of some such international language.

The growing popularity of Volapük has aroused philological students, and several other systems have been proposed since its introduction. In 1885 P. Steiner, of Germany, published a system entitled "Pasilengua," and in 1888 Dr. L. Samenhof, of Warsaw, an "International Language." Both these endeavor to produce a simple, regular system, with a vocabulary formed from existing Aryan words. Dr. Samenhof is credited with excellent judgment in his selections, and the vocabulary of both can be acquired with great ease, yet both use diacritical marks, sounds not common to all Aryan tongues, and grammatical complexities. The method proposed by Dr. Samenhof closely resembles that in use in the "agglutinative family" of languages. More recently, A. Melville Bell, the author of the system of "visible speech" for deaf mutes, has proposed what he calls "World English," based on the fact of the wide employment of English. It is simply English written on a phonetic system, with certain new consonantal signs and a simplification of English grammar.

The advantages of Volapük are given by the *Saturday Review*, as the following. Its words present no accumulation of heaped-up consonants or vowels, and there are no long compound words. It has no arbitrary rules of orthography, sparingly uses difficult sounds, and greatly decreases the number of words by its free use of inflections. This renders it useful for telegraphy. It is marked by clearness and precision, and freedom from ambiguous forms, while its numerous rhymes adapt it well to versification. It is

richer in forms than almost any other living language, and allows greater latitude in the construction of sentences. Yet it is not free from exceptions, such as that in which the preposition governs *mostly* the nominative. Exceptions of accent are also allowed in poetry.

The advantages above named are correlated with faults which must stand in the way of its general acceptance by Aryan nations. These faults have been pointed out by a committee of the American Philosophical Society appointed in 1887 to consider and report upon the newly proposed language. The report of the committee is shrewd and sensible in its suggestions, and we give an abstract of it, as showing the views of many linguists as to what a world language should be. The committee had for its chairman Prof. D. G. Brinton, the distinguished archæologist, the other members being Henry Phillips, Jr., and Monroe B. Snyder. They expressed the opinion that a universal language is greatly needed for the use of scientists, and also for the commercial and travelling world, but much less so for general literature, and that if adopted it is likely to be used as an addition to the native language of each people. Their report contains the following suggestions: 1st, the orthography of such a language should be absolutely phonetic; 2d, every letter should have but one sound; 3d, this sound should be common to all the leading Aryan languages; 4th, diphthongs, double consonants, etc., should be omitted; 5th, the meaning should never depend on tone, accent, quantity, or inflection of the voice; 6th, the vowels should be limited to the five pure vowels a, e, i, o, u, with the Italian pronunciation (these being common to all Aryan tongues); 7th, in consonants, all gutturals, aspirates, lisps, and nasals should be omitted, and all double and complex consonantal sounds; 8th, diacritical marks, accents, and apostrophes should be omitted, and all signs that cannot be made without lifting the pen (as the crossing of the t and the dotting of the i) avoided; 9th, all sounds should be easy to make and agreeable to the ear; 10th, brevity should be sedulously sought.

The vocabulary should be based on that common to the leading Aryan tongues. There are 1500 words in German almost the same as in English, and more than this common to English, French, Spanish, and Italian. At least a thousand words are common to all these languages, their main difference lying in pronunciation. Commercial, business, and scientific terms have much in common, the chief differences occurring in literary and art terms. The most important differences, and the least easy to obviate, are those between the grammatical forms of the several languages. In respect to grammar, the simplest method is the best. In a simplification of grammatical forms the interjection and article might be dispensed with. Several languages find no need of the latter. The adjective has neither gender, number, nor case in English, yet no difficulty arises in consequence, and therefore these modifications could be dispensed with. The distinction of form between the adjective and adverb might be omitted, as it often is in the spoken language. This would reduce the present nine parts of speech to six.

The comparison of adjectives by "more" and "most" is now practically the rule in the Romance languages, and might be generally adopted. The noun has no gender in English and modern Persian, though useless and annoying gender inflections are retained in all other Aryan tongues. The adjective of sex serves all necessary purposes of indicating gender in English. Number also could be usually dropped, as is now occasionally done. Case might be omitted. English retains only the genitive. Case can be readily replaced by pronouns and prepositions, as the genitive by the old use of "his" as in "John his book." Relative, interrogative, and demonstrative pronouns could be blended without confusion. The reflexive form is unnecessary, as is shown by English usage. In verbs all inflections

can be avoided by the use of auxiliaries, and the modern development of language has tended strongly in this direction. Most prepositions could be omitted by the arrangement of the sentence into verb, direct object, and indirect object. This simplification would yield an equal simplification in syntax, but would be attended with a loss to the flexibility of language. The logical arrangement of the sentence should be: the subject before the predicate; the noun before the adjective; the verb before the adverb; the immediate before the remote object. Internal inflection, and the use of prefixes, infixes, and suffixes should be avoided.

These suggestions, which are based on the tendencies manifested in the evolution of languages, and particularly of modern English, which has divested itself of the old inflectional methods more fully than any other modern language, are applied to the system of Volapük, which, as weighed in this balance, is found seriously wanting. It is, in the opinion of the committee, in conflict with the development of the Teutonic and Romance tongues alike, and is full of difficulties to the learner. It retains the impure German modified vowels, the French j and the aspirate h, and has 8 vowels and 19 consonants, where 5 vowels and 16 consonants would suffice. It has various diacritical marks of accent, tones, inflection, and quantity (all needless obstructions). Double consonants are numerous, and vowels are printed and written with underscoring and Italic letters to facilitate the comprehension of words. Several of the sounds used could not be pronounced by an Aryan without special oral training. Many words are manufactured from entirely new radicals, capriciously formed. Nouns are inflected through four cases, prefixes and suffixes commonly used—all this being out of accordance with the tendency of Aryan speech development. There is an excessive multiplication of inflectional forms; verbs are modified by 14 prefixes and 16 suffixes, and the meaning of a word largely depends upon its place in a sentence. The system of Volapük, in short, is absolutely opposed to the evolutionary tendencies of Aryan speech; it being synthetic and complex, while all modern dialects are growing more and more analytic and simple. It proposes a distinct retrogression in linguistics, a step backward toward conditions from which we have been for centuries escaping.

The committee, in conclusion, recommended the calling of a congress of philologists, for the purpose of devising an international language of the simplest and most advanced character possible, not for the purpose of supplanting existing tongues, but to add to them a general medium of international intercourse, and a common scientific and commercial language. In compliance with this recommendation the American Philosophical Society has taken steps to call together such a congress, composed of the most capable philologists of Europe and America, and it seems very probable that the instigation of Volapük will lead to the formation of a world language in every respect in harmony with the present state of the science and fully adapted to the needs of international intercourse.

(C. M.)

VOWS AND OATHS. In our English versions of the Bible the phrase "God forbid" (as distinguished from "the LORD forbid," See Vol. XXIV. p. 300 (p. 320 Am. Rep.). or "my God forbid") occurs eight times in the Old Testament, and fifteen times in the New Testament. Neither the Hebrew nor the Greek phrase so translated contains the name of the Supreme Being, either expressly or by implication. The phrase "God save the king" occurs eight times; in each case the Hebrew is simply "Live the king." We are in these cases accustomed to translate the Hebrew or Greek phrases, not by English words that correspond with the words of the original, but by English idiomatic phrases that are conceived of as conveying, on the whole, the same meaning with the original, and these English phrases came into the language

from other than Biblical sources. These peculiarities of translation have something of a typical character. In the matter of appeals to the Supreme Being, either in oaths or vows, the ideas of Christian peoples are more or less colored by notions of heathen origin. This appears in our current religious phraseology, our hymnology, our interpretations of Scripture.

The fundamental law concerning vows is stated in Deut. xxiii. 21-23. They are often mentioned in connection with freewill offerings, with which they have this in common, that they are required from no one; the law simply regulates them, in case any one deems it a privilege to offer them. But the limits within which the vow is permitted are narrower than those of the freewill offering. For example, no vow to offer an animal in sacrifice is permitted, unless the animal is without blemish. When a vow has once been legally made the legal accomplishment of it is rigidly exacted. But it is evident that the vow was commonly thought of rather as a form of prayer, or of public confession and thanksgiving, than as a bond upon the person making it. This is strikingly illustrated by the fact that the current word for it in the Septuagint and the New Testament is *εὐχή*, prayer, while the most common variants are other forms of *εὐχόμεαι*, and the word *ὁμολογία*, signifying public confession. The interpretation thus given to the Old Testament word fits its use as far back as this can be traced. It follows from this that vows are not presented, in the Bible, as modes of bribing the Supreme Being for his interference, or of paying him for favors, but rather as a method of prayer and an expression of praise and gratitude.

The Biblical vow is ordinarily a promise to offer some sacrifice, or perform some ritual act, or render some other external service. The services vowed are always external, and ordinarily temporary, not spiritual or perpetual, though of course the spirit with which a vow was performed was regarded as all important. The law of the devoted things, Lev. xxvii. 21-29, Num. xviii. 14, cf. Josh. vi. vii., is not an exception to this statement, for the "herem" is a different thing from a vow. The case of the Nazirite for life is not an exception, as we shall presently see. The case of Jacob's accepted vow, Gen. xxviii. 20-22, xxxi. 13, is not an exception, for the words "Jehovah will be to me for God" properly close the protasis of the sentence, instead of beginning the apodosis. Jacob did not vow that if Jehovah would go with him and supply his wants and bring him back, then Jehovah should be his God, but that if Jehovah, fulfilling the promises he has just made to be with him and bring him back, would be his God (verses 13-15, cf. xvii. 7), then Jacob would make his memorial stone a house of God, and would give tithes.

The article in the *ENCYCLOPÆDIA BRITANNICA* mentions the prominence given in the Roman Catholic Church to irrevocable vows of certain sorts. Solemn promises made to God, having something of the nature of vows, are quite common among Protestants. To say nothing of Brotherhoods and Sisterhoods, formed more or less upon the Roman model, we have the solemn promises made by ministers at licensure or ordination, those made by ministers and people at the institution of the pastoral office, those often made at the receiving of persons into covenant with the church, the pledges of the various Christian Associations, Christian Endeavor Societies, Temperance Societies, and many others of the same general character. As to all such matters, it should be remembered that while a pledge of this kind, used within Scriptural limits, may be a privilege and a help, there is great danger of our making it the contrary. If we permit vows of this kind to take the place in our lives that belongs to love or conscience or the grace of God, the vow will become a burden and a snare.

From the point of view of those who regard the Biblical account of the origin of the Mosaic legislation

as historical, the vow of Jephthah, Jud. xi., must be regarded as illegal. He had no right to vow a burnt-offering to Jehovah, except as he limited the vow to animals legally fit for that purpose. We have here an account of a rash man who had military gifts and who was used by Jehovah, but whose religious position by no means indicates the true character of the religion of Jehovah at that period. There is nothing to show that either Jephthah's vow or that of Hannah, 1 Sam. i. 11, were cases that would fall within the law of redemption given in Lev. xxvii., and there is therefore nothing in these cases to show that that law was then non-existent. Instead of saying "the principle that a vow once taken must be fulfilled at any cost was so far modified in later times in Israel that exceptional vows were by law redeemed at a valuation," it would doubtless be correct to say that from the times of Moses the law provided for a class of vows that might be so redeemed.

In the article NAZARITE or NAZIRITE, in the *ENCYCLOPÆDIA BRITANNICA*, it is asserted that "the Hebrew root N-Z-R is only dialectically different from N-D-R, to vow." This is in one sense true, but not in the sense that would justify the inference "that the peculiar marks of the Nazirite are primarily no more than the usual sign that a man is under a vow of some kind." Any one will be convinced of this who will notice the distinctness with which the two words are used in Num. vi., and throughout the Old Testament. Whatever might supposedly be true of the two words, if they belonged to different dialects, it is a matter of fact that in Hebrew usage they are sharply differentiated.

The statement that the law of the Nazirite, as found in Num. vi., "is not pre-exilic," is, of course, contrary to the explicit testimony of Num. vi. 1, which attributes the law to Moses. Very likely it may be true that this law is "directed to the regulation of a known usage," but there were already such things as existing usages in the times of Moses. Further, the fact that the law contemplates one form of Nazirite usage does not render it incredible that other forms of it may have existed. The case presented in Num. vi. is that of a temporary Nazirite usage by vow; the case of Samson (perhaps that of Samuel also) is the different case of a person who is a Nazirite for life by divine appointment, independent of any vow made by himself. If we regard these cases as two species of a common genus, then the fact of the existence of one species in the times of the judges indicates the probable existence of the other species rather than proves it to be nonexistent in those times. And in any case, the variations between the case of Samson and the description given in Num. vi. have no weight to prove that the law in Num. vi. had not then been given; for the variations may either be due to the difference between the condition of a Nazirite for life and a Nazirite for a limited period, or may be accounted for like the other prevalent negligences and irregularities in the observances of the national laws that were prevalent in the times of Manoah and Eli. (W. J. B.)

VULPIAN, EDMÉ FÉLIX ALFRED (1826-1887), French physiologist, was born at Paris, Jan. 5, 1826. In 1854 he graduated at the Medical School, and becoming assistant in the Museum of Natural History pursued researches on the nervous system. In 1867 he was, despite of the charges of materialism made against him by the bishop of Sura, called to the chair of pathological anatomy in the Medical School. In 1868 his teachings were attacked during the discussion of a petition against the instruction in that school, but Vulpian maintained an attitude of such dignity that he acquired the esteem of the scientific world, and in the next year was made member of the Academy of Medicine. In 1872 he passed to the chair of experimental and comparative pathology, and in 1875 was made dean of the faculty. In 1876 he was chosen member of the Academy of Sciences. By his

erudition and the strictly scientific methods evinced in his researches on the nervous system he attained to the first rank among physiologists. He died at Paris, May 18, 1887. His important works are *Des Pneumones secondaires* (1860); *Leçons sur la Physiologie générale et comparée du Système nerveux* (1866), the

work which founded his reputation; *Leçons sur l'appareil vaso-moteur* (2 vols., 1875), in which he subjects previous works to the rigid tests of experimentation; *Clinique médicale de l'Hôpital de la Charité* (1878); *Maladies du Système nerveux* (1879).

W.

WACE, HENRY, English clergyman and author, was born in London, Dec. 10, 1836. He was educated at Brasenose College, Oxford, and graduated B. A. in 1860. Having taken orders he was curate in London from 1861 to 1869, and chaplain of Lincoln's Inn from 1872 to 1880. He was also professor of ecclesiastical history in King's College, London, from 1875 to 1883, and since that date has been its principal. He has also been prebendary in St. Paul's Cathedral since 1881, and has been select preacher at the universities of Oxford and Cambridge. He has published *Christianity and Morality*, Boyle lectures (1876); *The Foundations of Faith*, Bampton lectures (1880); *The Gospel and its Witnesses* (1883); *Student's Manual of the Evidences of Christianity* (1886). With Dr. William Smith he edited the valuable *Dictionary of Christian Biography* (4 vols., 1880-86). This work treats with scholarly fulness and accuracy of the literature, sects, and doctrines, from the time of the apostles to the age of Charlemagne. Dr. Wace is the author of the *Commentary on the Apocrypha* (1886) in what is called the *Speaker's Commentary*. He has been associated with Prof. Buehheim in editing the *First Principles of the Reformation* (1884).

WADDINGTON, WILLIAM HENRY, French archæologist and statesman, was born of English parents, Dec. 11, 1826, at Saint-Remi (Eure-et Loire). His education was commenced in Paris, and completed at the University of Cambridge. Thence he returned to France, and chose it for his nationality. Possessed of fortune, he gave himself to antiquarian and numismatic pursuits, and became member of the Society of Antiquaries. The results of a journey in 1850 in Asia Minor, which he published in two *Memoirs*, were crowned by the Academy of Inscriptions, of which institution he was chosen a member in 1865. Elected from the department of Aisné in 1871 to the national assembly, he soon obtained note by his report of the law for the organization of the councils general. At first he ranked himself with the right centre, but, after his brief occupancy of the post of minister of public instruction for five days in May, 1873, at the end of M. Thiers' presidency, Waddington generally voted with the left centre. He gave his vote for the law which restricted the right of suffrage till the age of twenty-five. In May, 1874, after the fall of the Duc de Broglie, he declined a portfolio in the new cabinet; voted against the law for freedom from state control in higher instruction, and supported the Republican constitution. He was elected senator from Aisné in 1876, but very soon in the Dufaure cabinet took the position of minister of public instruction, from which the department of public worship was then separated. He enforced compulsory primary education and the governmental control of all educational institutions. In the department of higher instruction he aimed at the grouping of the faculties in the powerful and complete universities, the establishment of private courses of study directed by the faculties, the development of libraries, laboratories, and collections, and urged the creation of scholarships for poor students. He changed some colleges into lycées, instituted faculties of law at Bordeaux and Douai. He retained his portfolio when Jules Simon became premier, but resigned

it five months afterward (May 16, 1877), and in the next month he voted in the senate against the dissolution of the chamber of deputies. In the following December he entered the new cabinet of Dufaure as minister of foreign affairs. He acted as the French plenipotentiary at the congress of Berlin (June, 1878), and claimed for Roumania and Servia freedom of religion and political equality, conformably to the law of modern civilization. He stoutly insisted on the rectification of the boundaries between Greece and Turkey. On his return to France he announced to his government its honorable re-entry in the councils of the great powers, and was complimented by M. Dufaure in a public letter. After Marshal MacMahon's resignation of the presidency and Dufaure's retirement, Waddington, under the presidency of M. Grévy, while retaining the ministry of foreign affairs, accepted in February, 1879, the presidency of the council. He was then antagonized by the senate as too republican, and by the chamber as too moderate. Notwithstanding, he protested against the prosecution of the late ministry of MacMahon on the one hand, and on the other against an entire amnesty. Despite the dissatisfaction of a portion of the Republicans of the chamber, he obtained a vote of confidence, Dec. 2, 1879. But four weeks later he resigned both his positions, whereupon he was offered the ambassadorship to England, which he declined. Besides the *Memoirs*, mentioned above, he has written *Mélanges de Numismatique et de Philologie* (1861); *Édit de Dioclétien* (1864); *Voyage archéologique en Grèce et en Asie Mineure* (1868-77).

WADE, BENJAMIN (1800-1878), senator, son of a soldier of the Revolution, was born near Springfield, Mass., Oct. 27, 1800. The family was in very humble circumstances, and what the boy learned was from his mother. In 1818 he migrated to Northern Ohio, and supported himself by farm-work, and driving cattle to New York, with intervals of teaching school and shovelling on the Erie Canal. He managed to study law, began practice in 1828, and after the usual waiting for clients was made prosecuting attorney of Ashtabula county in 1835. In 1837 he was sent to the State senate, where he was soon known as an outspoken opponent of the slave system and its concomitants in the North. Popular opinion on this subject in Ohio was not then what it afterward became, and Wade's hostility to the State "black laws" incurred such odium as relegated him to private life. After his re-election he had charge of the bill which incorporated Oberlin College. He became president judge of the Third Ohio district in 1847. The dignity of the bench did not repress his political activity; after the sessions of his court he made speeches in the campaign for Taylor, whom, though a slaveholder, he preferred to Van Buren. His reputation was no more than local when he was sent to the U. S. Senate as a Whig in 1851; but in the national arena he speedily made himself felt, and was a striking figure for eighteen years. A hearty hater, with the full courage of his convictions, untroubled by delicate scruples, consideration for opponents, or the philosophic habit of looking at both sides, he was in his element in the rude struggles which preceded the conflict of arms. His

rough and ready frankness and immovable determination were a set-off to "plantation manners," and he was of use in making felt the ripening Northern will and purpose, where more refined men and measures might have failed. When challenged by a Southern Senator, he so conducted himself as to bewilder and overawe his adversaries. His rebuke to Douglas, during the debate on the Kansas-Nebraska bill, however unparliamentary, was effective. He earned the respect of Toombs, who bore public witness to his manly sincerity and directness. With five others he voted in 1852 to repeal the Fugitive Slave law. He opposed the Lecompton constitution for Kansas, the proposed purchase of Cuba, and every measure in the interest of slavery. He advocated negro suffrage in the District of Columbia; and pushed the Homestead bill till it was passed in 1862. He earned the familiar appellations of "honest Ben Wade," "the old Roman," and the like. The war he may be said to have enjoyed, urging emancipation and confiscation from the start, and as chairman of the Joint Committee on its conduct rendering real service. To the era of reconstruction he was ill adapted, for moderation and mercy were neither in his views nor in his temper. He opposed a second term for Lincoln, and as president of the Senate vehemently urged the impeachment of Pres. Johnson. Counsels of this kind had not a happy effect when the war was over, a fact which he seemed unwilling to realize. By 1869 he was no longer needed in the Senate, nor was he invited to the Cabinet, but his retirement was softened by a commissionership on the Pacific Railroad. In 1871 he was on the Santo Domingo Commission, and favored annexation. He was last heard of in 1877 as violently opposing the mild policy of Pres. Hayes toward the South. An ardent reformer while the battle of principles was in progress, he could not accept results and be content when the victory was won. He died at Jefferson, Ohio, March 2, 1878. See his *Life*, by A. G. Riddle (1886.)

WAGES. See **AGRICULTURE**, Chap. X., **LABOR** and **STRIKES**.

WAITE, MORRISON REMICK (1816-1888), chief-justice of the United States, was born at Lyme, Conn., Nov. 29, 1816. Having graduated at Yale College in 1837, he removed to Ohio, where he completed his legal studies and engaged in the practice of the law at Toledo. He filled no national office until selected by Pres. Grant in 1872 to represent the United States at Geneva before the tribunal of arbitration on the Alabama claims under the treaty of Washington with Great Britain. While presiding over a convention for the revision of the constitution of Ohio he was nominated by Pres. Grant to the office of Chief-Justice of the Supreme Court of the United States, and entered on its duties March 4, 1874. He held that office until his death, which occurred on March 23, 1888.

Prior to the sickness that terminated his life he had prepared an elaborate opinion in the telephone cases that had been for many months before the Supreme Court involving the validity of the Bell telephone patents. Before he had obtained entire relief from the indisposition which had affected him he took his place upon the bench, on March 19th, for the purpose of delivering the judgment of the court in the telephone cases. He remained in court while the opinion was read by another and then returned to his bed, from which he never arose.

Chief-Justice Waite was called to preside over the Supreme Court at a period that marks one of the great stages in the history of that court. The rebellion of 1860 had been suppressed and the period of reconstruction had passed, during which the powers of the government had been strained to meet the exigencies that threatened the national unity if not its existence, and it now devolved upon the court over which he presided to readjust the civil relations that had been disturbed during this exciting period in conformity with sound views of the nature and limitations of

the public authority. In a political sense the period under consideration was necessarily one of conservative reaction and it was to be anticipated that the action of the court would reflect that tendency. The vast increase of business transacted by the court was another peculiar feature of this period, and a relatively large proportion of that business related to public and corporate obligations. The war had given a great impetus to the extension of railways, connecting together all parts of the country from the Atlantic to the Pacific and from the Lakes to the Gulf, and the adjustment of the legal relations arising from such interests brought to the court an extended and complicated branch of business. The crowded state of the calendar of the court rendered the despatch of business the most pressing necessity of the conduct of its business.

In the early years of the Supreme Court, when the structural lines given by the Constitution were to be transferred to the institutions and habits of intercourse of a young and growing society, and that court was the organ of such adjustments, and when the national impulses and local predilections of men read the purposes of that Constitution in opposite senses, a mind comprehensive and exact, animated by the genius of our national institutions and sensitive to the balance of our complicated legal system, was needed in the chief seat of that court to inspire and mould its deliberations, and that mind was found in John Marshall (for whom see *ENCYCLOPEDIA BRITANNICA*). The occasion was great and the man was equal to the demand of its exigencies. Before that day nations had arisen and become great under the arbitrament of the sword, but the spectacle of a nation planned in council and habituated under the genial sway of judicial reason was new to the world.

As the first great period in the history of the court demanded an idealism that could grasp the possibilities of American civilization, so the second period demanded a robust administration to give fibre to that which had been fashioned by his great predecessor. The court over which Chief-Justice Taney (*q. v.*) presided did not fail to meet what was promised by its ability and demanded by the state of the country, until the dark shadow of the rebellion of 1860 disturbed its equanimity.

The third great period may be regarded as commencing at the accession of Chief-Justice Waite to its first office. The necessity for settling great fundamental political questions appeared to have passed, and the early doctrines of the court had passed into full acceptance and had been clearly illustrated and defined. The industrial development made the chief demand upon the attention of the court. Commercial enterprises embodying the national spirit that emerged with fresh animation from the unities of purpose and action brought about by the war passed from local to interstate relationships, thus widening the area of federal jurisdiction and crowding the court with a great volume of business that overtasked its means of discharging such grave public duties. Under such circumstances an able administrator was what was needed at the head of the court and such an officer was found in Chief-Justice Waite. With the depressing fact ever present in the mind of the court that its suitors must wait three years to be heard before it, it is not surprising that the adornments of oratory should largely disappear from the court, replaced by frictionless machinery without heat or scintillation. The mental constitution of Chief-Justice Waite was not at variance with the necessities that thus affected the court, for he regarded it as a place for the transaction of business and its chief duty beyond that of deciding properly to be the expedition of its business. If the overtasked powers of the bench did not admit of the realization of the forensic models of Rome and Greece that was no deprivation to the Chief-Justice, who entertained English ideas of methods of advocacy. A concise and

clear statement of facts and a skeleton of an argument emphasized at its salient points satisfied in his mind the demands of the duty of the advocate and the convenience of the court.

It often happens that the advocate in the course of examining a proposition of law under its limited application to a case under consideration sees it in its broad relations, and thus obtains a standpoint from which its specific applications can be most accurately judged. In such cases it is natural that he should endeavor to lead the court to the same standpoint, and if the prevailing methods of presentation and the state of business in the court do not admit of such an effort it is a grave misfortune. Whenever our jurisprudence reaches the last term of its development, it will be possible to administer it by mechanical methods, but so long as it is to meet new conditions and exhibit expansive qualities the required conditions must be found in the methods and mind of the court. A close adherence to English forensic methods is not practicable for the mind or conditions of America. The English jurists adhere to antecedent forms and draw their reasonings from limited authoritative sources, avoiding generalizations that embrace elements that have not this technical sanction; while the American jurist recognizes that the conditions of our national life demand progressive changes, and he seeks to conserve substance rather than form as derived from the past, and admits the principles of nature and social order into his generalizations although not recognized by his juridical predecessors. The English jurist aims to perpetuate existing forms of legal institutions, while his American brother looks to higher adaptations of existing methods than have yet been reached.

Under the tendency that has just been stated American constitutional law has sprung into existence, which owes its development to a breadth of generalization excluded from English forensic methods. It may be said that the stage of the expansive development of American jurisprudence has passed, and it may be true that the most active period in that respect has gone by, but there is nothing in retrospect or forecast to warrant the opinion that a stage of development has been reached that will impose on the jurists of this country no more arduous duty than that of conserving its forms and principles.

Chief-Justice Waite possessed that trained legal sense, by which conclusions are drawn before the reasons on which they rest are consciously recognized, and which is the first condition of a sound legal judgment. This quality apprehends the fitness of things in a legal sense before their details are examined, and is in fact a generalization based on broad legal experience without which legal inquiry is in danger of being lost in technicalities and minutiae. If confidence in the possession and value of this quality sometimes disinclines its possessor to painstaking efforts for the verification of his results, on the other hand its absence or weakness leaves opinion without anchorage in the sense in which the term opinion is put in contrast with that of conviction. In the scientific branch of legal work, which consists in testing the generalizations drawn in the manner just pointed out by the results of antecedent judicial decisions, many have surpassed Chief-Justice Waite, and the same may be said as to that rare quality by which legal principles are unfolded in their nature and applications.

In his personal bearing as a judicial officer Chief-Justice Waite was kind and considerate, and, although the flowers of rhetoric did not flourish under his touch, kindly feelings habitually remained with those who had judicial intercourse with him.

See "Memorial Proceedings in Supreme Court," *U. S. Reports*, Vol. 126, Appendix. (A. J. W.)

WALKER, AMASA (1799-1875), economist, was born at Woodstock, Conn., May 4, 1799; his ancestry settled at Charlestown, Mass., 1641. From 1825 to 1840 he was engaged in business in Boston, and active

in the temperance and anti-slavery movements. From 1843 his home was at North Brookfield, Mass., but for some years he visited Oberlin, Ohio, as professor of political economy. He was sent to the Massachusetts assembly 1848 and to the senate 1849, was secretary of state 1851-2, member of the Massachusetts Constitutional convention 1852-3, of Congress 1862-3, and lecturer on political economy at Amherst College from 1861. He died Oct. 29, 1875. He was one of three editors of the *Transactions* of the Massachusetts Agricultural Society, 1848-54. He wrote much on his favorite subject for periodicals, and published *Nature and Uses of Money* (1857), and *Science of Wealth* (1866). The latter was widely read, and gained much repute and influence.

His son, FRANCIS AMASA WALKER, statistician and educator, was born in Boston, July 2, 1840, and graduated at Amherst College in 1860. His legal studies were interrupted by the war, in which he became adjutant-general of Gen. D. N. Couch's division in 1862, and colonel in 1863. He was wounded at Chancellorsville, taken prisoner, and emerged from the strife with broken health and the brevet of brigadier-general. After teaching for two years at Williston Seminary, Easthampton, Mass., and editing the *Springfield Republican* for a year, he was appointed chief of the bureau of statistics at Washington 1869, superintendent of the Ninth Census 1870, and Indian commissioner 1871. He became professor of political economy and history in the Sheffield Scientific School of Yale College 1872, and president of the Massachusetts Institute of Technology in Boston 1881. Besides three volumes of census reports and a *Statistical Atlas of the United States* (1874), he has published *The Indian Question* (1873); *The Wages Question* (1876), *The World's Fair* (1876); *Money in its Relation to Trade and Industry* (1879); *Political Economy* (1882), in the "American Science Series"; *Land and its Rent* (1883), and *History of the Second Corps, Army of the Potomac* (1886).

WALKER, ROBERT JAMES (1801-1869), statesman, was born at Northumberland, Pa., July 19, 1801, and graduated at the University of Pennsylvania 1819. He began to practise law at Pittsburg 1819, became an active Democrat, and removed in 1826 to Natchez, Miss., where he rose to prominence. Always a Unionist, he resisted the nullifiers in 1833. The next year he published *Reports of Cases in the Supreme Court of Mississippi* (1818-32). Elected to the U. S. Senate 1836, he introduced the earliest Homestead bill, supported Van Buren's measures, and urged the recognition of the independence of Texas in 1837, and afterwards its annexation. He had much influence with Pres. Tyler, and helped to effect the nomination of Polk, who made him secretary of state in 1845. In this office he actively favored free trade, procured a reciprocity treaty with Canada, and introduced the warehousing system. The Department of the Interior was established at his suggestion. His later posts were of less eminent rank, but afforded opportunities of honorable service. In 1853 he was a commissioner to open commercial relations with China and Japan. In 1857, as fourth governor of Kansas, he repeated the doubtful but enlightening experiences of his predecessors (Reeder, Shannon, and Geary), and declared himself "unwilling to aid in forcing slavery on Kansas by fraud and forgery." As in this case he broke with Buchanan's administration and the slave power, so in the war he would not go with his adopted section. As U. S. financial agent in Europe during most of 1863-4, he negotiated \$250,000,000 of the 5-20 bonds, and prevented the sale of the second Confederate loan of \$75,000,000. During these years he edited the *Continental Monthly*, and wrote for it some letters on American resources, which exerted an influence abroad and won high praise. He advocated the purchase of the Danish West Indies and Alaska, and the construction of the Pacific Railroad. As a friend of peace and of both sections, he

opposed the impeachment of Pres. Johnson, and the carrying out of the Congressional Reconstruction measures in Mississippi. He died Nov. 11, 1869, at Washington, where he was prominent at the bar.

WALKER, WILLIAM (1824-1860), filibuster, was born at Nashville, Tenn., May 8, 1824. After traveling abroad, studying medicine in Paris, and being admitted to the bar, he was connected for a time with the New Orleans *Crescent* and the San Francisco *Herald*, and practised law at Marysville, Cal. In October, 1853, he undertook a fantastic enterprise against the north-western states of Mexico. Landing with a few comrades at La Paz on the end of the Californian peninsula, he proclaimed himself president of the country, "annexed" Sonora, and marched northward, only to surrender at San Diego. In May, 1854, he was tried at San Francisco for a violation of the neutrality laws and acquitted. Invited to Nicaragua, he landed at Ruelijo in June, 1855, raised a force, won in a few actions, took Granada, Oct. 15, and executed a native general for "treason." In a war with Costa Rica he retrieved a defeat in March, 1856, by a victory in April. "Elected" president in June, he issued currency on a large scale, re-established slavery, and was recognized by Pres. Pierce. His intrusive tyranny provoked a revolt, and the opposition of the Vanderbilt Steamship Company, whose property he had confiscated, contributed to his downfall. After burning Granada, he surrendered May 1, 1857, to Commodore C. H. Davis, and was sent to New Orleans, whence he escaped to make another effort, but within two weeks was taken by another U. S. naval officer, and conveyed to New York. His madness was encouraged by sympathy at home, and Pres. Buchanan ordered his release in January, 1858. In the fall he started again, but was arrested, tried in New Orleans, and acquitted. His curiously unamiable fanaticism despised all lessons of experience, and in June, 1860, he landed at Truxillo, in Honduras. Two months later he was driven from the town by a British war-vessel; marching into the country with a small force, he was captured by the native authorities, and shot Sept. 8, at Truxillo. He represented no American or rational principle, and accomplished no good end: his reckless exploits belong rather to mediæval than modern manners, but he is unregretfully remembered as "the gray-eyed man of destiny," and the chief of "filibusters." His account of *The War in Nicaragua*, written before his last expedition, appeared at Mobile, 1862.

WALLACE, ALFRED RUSSEL, an eminent English naturalist, was born at Usk, Monmouthshire, Jan. 8, 1822. He received his education at the grammar school of Hertford, and was articled to an elder brother who pursued the business of land surveyor and architect. Early in life, however, he gave up this pursuit in favor of the study of natural history, and in 1848 accompanied the naturalist Henry Walter Bates on a scientific expedition to Brazil. They made a long sojourn in Pará, engaged in a scientific exploration of the vicinity, and then started on a voyage of exploration of the forest region of the Amazon and Rio Negro rivers, from which they returned to England in 1852. During this journey Wallace obtained a somewhat extended vocabulary of the Indian languages of the Amazon valley, and a valuable collection of scientific material, which was very rich in the departments of botany and ornithology. Unfortunately, the greater part of this was lost in a shipwreck. In 1853 he published *Travels on the Amazon and Rio Negro, with Remarks on the Vocabulary of the Amazonian Languages*, which work was followed by *The Palm Trees of the Amazon, and their Uses*.

In 1854 he set out on a yet more important scientific journey, the field of his exploration being now the islands of the Malay Archipelago, in which region he remained for eight years, passing from island to island, and extending his expeditions to the island of

New Guinea, then almost unknown for scientific purposes. This long period Wallace occupied in the most ardent and enthusiastic natural history labors, resulting in the collection of an extraordinarily rich cabinet of zoological specimens, including more than 100,000 insects and over 8000 birds. Among his special studies were the habits of the orang utan, and, while in New Guinea, the birds of paradise, peculiar to that island. To him we owe the earliest satisfactory account of the habits and haunts of this most beautiful family of birds. He succeeded in adding to those already known a new species, the Standard Wing (*Semioptera Wallacei*), distinguished by a pair of long, narrow white feathers, springing from the bend of the wing, and capable of being erected at the bird's pleasure. While thus engaged his mind was also occupied with the study of the mystery of the origin of species which has during the present century exercised the intellects of so many able naturalists. The result of his thoughts was the conception of an idea of animal derivation remarkably similar to Darwin's celebrated theory of natural selection, and the parallel is the more interesting from the fact that the announcement of the results of Wallace's and Darwin's studies was made on the same day and before the same scientific body. Wallace embodied his theory in a paper entitled "On the Tendency of Varieties to depart indefinitely from the Original Type," which he sent to the Linnæan Society through Sir Charles Lyell. It was read on July 1, 1858; and at the same meeting was read Darwin's paper "On the Tendency of Species to Form Varieties, and on the Perpetuation of Species and Varieties by means of Natural Selection," which contained the first public statement of his celebrated theory. Wallace recognized natural selection as the agent in producing most of the changes pointed out by Darwin, but denied its sufficiency, without aid from some higher power, to explain the origin of the human species. Though the two naturalists arrived at this theory independently of each other, the priority has been given to Darwin, who had privately described his theory to scientific friends several years before, had conceived it many years previously, and published a detailed exposition of it immediately after the first public announcement, with a wealth of illustrations, the results of his own studies, far in excess of anything that Wallace had to offer.

In 1862 Wallace returned to England, where he spent several years in arranging and classifying his vast collection and in writing a popular account of his explorations, which was published under the title of *The Malay Archipelago, the Land of the Orang-utan and the Bird of Paradise* (1869), and ranks among the most entertaining and instructive narratives of scientific exploration. He also published many papers in the proceedings of the Linnæan, Zoological, Ethnological, Anthropological, and Entomological Societies, a collection of which was issued in 1870, entitled *Contributions to the Theory of Natural Selection*. In 1868 he received, in acknowledgment of the high value of his scientific labors, the gold medal of the Royal Society, and in 1870 the gold medal of the Geographical Society of Paris. The works above named were followed in 1876 by the most valuable of his scientific productions, an elaborate work *On the Geographical Distribution of Animals*, which was issued in English, French, and German, and yet remains the standard work on the subject. In the same year he was president of the Biological section of the British Association in its meeting at Glasgow. His other scientific works comprise *Tropical Nature* (1878), which contains his latest views on the colors of natural objects, sexual selection, geographical distribution, etc.; and *Island Life* (1880), in which he considers the phenomena presented by the faunas and floras of the principal islands of the globe and the problem of geological climates. He has also edited a work on Australasia, chiefly written by himself. In 1882 he

received from the University of Dublin the honorary degree of D. C. L.

Wallace's attention has not been confined to scientific subjects. After his return from the Pacific islands he gave much attention to the phenomena of spiritualism, into which he made close researches, with the result of becoming firmly convinced that they were actually the work of disembodied spirits. The results of his observations in this direction were published in 1874 in a series of essays in the *Fortnightly Review*, which were afterwards reprinted under the title, *Miracles and Modern Spiritualism* (1875). Since that date Wallace has written little upon the subject, but is said to be still a firm believer in the spirit origin of these phenomena. At a later date he became strongly interested in social and political problems, and published *Land Nationalization, its Necessity and Aims* (1882), in which he gave a sketch of the whole subject of the tenure of land, and proposed a scheme of occupancy under state control which he believed would remedy the numerous evils of the present system of land-holding. For the advocacy and promotion of this scheme a Land Nationalization Society has been formed, with Wallace as its presiding officer. A later economic publication is his *Bad Times, with Suggested Remedies* (1885).

As a scientific thinker and observer Wallace occupies a high position in the annals of modern science, yet in the former has not attained the standing to which his mental acumen seems to entitle him. Unlike his fellow-theorist, Charles Darwin, he has not devoted his life to the elucidation of a single problem, or attempted the exhaustive treatment of any topic, but has given his attention to subject after subject without an effort to probe any one to the bottom. While unusually quick in the appreciation of causes and principles, as evidenced in his theory of natural selection and many minor theoretical views, it is rather quickness than depth, his conceptions being reached at a leap, as it were, and never pursued to their ultimate with the hard and persistent labor of the great masters of thought. His scientific friends say that he is almost intuitive in his readiness in solving a problem in natural history, but his quickness does not seem combined with persistence, and, with all his fine powers of thought, he has failed to win the leading position in science which some of less native brilliancy of thought have attained. As a writer he is comprehensible and pleasing, his works being clearly and attractively written, and full of that enthusiasm in his subject which is needed to arouse the interest of the reader to its fullest extent. They have been widely read and have aided much in the popularization of science. (C. M.)

WALLACE, LEWIS, general and author, was born in Fountain co., Ind., in 1827, son of David Wallace (1799-1859), formerly governor of that State. He studied law and was admitted to the bar, but during the Mexican war threw up his practice and joined the army as second lieutenant of First Indiana Volunteers. After the war he returned to the practice of his profession in his native State, of whose senate he was member for a year. At the outbreak of the rebellion he was adjutant-general of Indiana, but in April, 1861, he was chosen to the command of the Eleventh Indiana Volunteers (three-months' men), and served with it in West Virginia, at the capture of Romney, and elsewhere. This regiment's term expired in August, 1861, but, mainly through his zeal and influence, it was forthwith reorganized under his command. In September he received his commission as brigadier-general of volunteers, and was for a time stationed in Kentucky. He commanded a division at the capture of Fort Donelson, occupying the centre of the National lines, and manifested such gallantry and skill that he was promoted major-general of volunteers, March 21, 1862. In the battle of Shiloh his division occupied Crump's Landing, on the Tennessee, some 8 miles lower down

than the field of battle, and was not engaged the first day. On the second day it rendered efficient service, as it did also in the subsequent advance on Corinth. In the court of inquiry, which sat in November to inquire into the conduct of Gen. Buell, Gen. Wallace was president. In 1863 he prevented the capture of Cincinnati by Gen. Kirby Smith, and was next year assigned to the command of the Middle Department and Eighth Army Corps, with which he met Early marching on Washington, but was defeated by him on the banks of the Monocacy, Maryland, July 9, 1864. On this Gen. Ord was directed by Halleck to supersede Wallace, but Grant promptly reinstated him. He had, in fact, succeeded in his main object, which was to give Grant time to reinforce Washington from City Point. He was a member of the commission which sat in 1865 for the trial of the persons implicated in the assassination of Pres. Lincoln and the attempt on the life of Sec. Seward, and was president of the court that tried Capt. Wirz, of Andersonville prison. After the war Gen. Wallace engaged in the practice of law at Crawfordsville, Ind. Here also he wrote his first work of fiction, *The Fair God* (1873), a story of Mexico. In 1881 he was sent as U. S. minister to Constantinople, and in next year was made envoy extraordinary and minister plenipotentiary at the same court. He returned to the United States in 1885.

Gen. Wallace has shown uncommon faculty of turning to new subjects of diverse kinds, and mastering them with the zeal and enjoyment of youth. He was distinguished as a soldier, a general, and a lawyer; he handles the brush with the facility of an artist. Few literary productions have so suddenly leapt into fame as his *Ben Hur* (1880, New York). The circulation of the latter work has been quite phenomenal, and an eminent critic has said, "*Ben Hur* is altogether the most noteworthy novel ever written by an American." In 1888 these were succeeded by another work, *The Boyhood of Christ*, in which he has made use of the stories in the Apocryphal Gospels. For the Presidential campaign of 1888 he wrote a biography of his friend, Gen. Benjamin Harrison. In *Harper's Magazine* for January, 1889, he published a tragedy in blank verse, entitled *Commodus*. Gen. Wallace resides in Crawfordsville, Ind., mainly occupied with literary work. His wife, Mrs. Susan E. Wallace, is a brilliant and picturesque writer of historical and descriptive sketches.

WALLACE, WILLIAM HARVEY LAMB (1821-1862), general, was born at Urbana, Ohio, July 8, 1821. In 1833 he removed with his father to Illinois, where he studied law in Springfield and Ottawa. On the occurrence of the Mexican war, he enlisted in Col. Hardin's regiment, the First Illinois Volunteers, rising to be lieutenant and adjutant and was engaged in the battle of Buena Vista. In 1853 he was elected State attorney for the 9th circuit of Illinois, and in May, 1861, he was commissioned colonel of the Eleventh Illinois regiment. At the capture of Fort Donelson in February, 1862, he commanded a brigade in McClelland's division and bore so conspicuous a part that on March 21 he was promoted brigadier-general. At the battle of Shiloh he commanded the division of Gen. C. F. Smith, absent on account of sickness. When the three other divisions were routed, Wallace, in conjunction with Gen. Hurlbut, for six hours held the field against the force of the enemy flushed with victory. At the end of the struggle Gen. Wallace fell mortally wounded, "closing in death," says Horace Greeley, "a day's work which had won for him the admiration of all beholders and the gratitude of his country." He died at Savannah, Tenn., April 8, 1862.

WALSH, ROBERT (1784-1859), author and journalist, was born in Baltimore in 1784, and was educated at the Catholic College there and Georgetown College, D. C. After completing his course he went to Europe, where he remained until his twenty-fifth

year. On his return he studied law but soon abandoned it for literature, beginning his career on *Dennie's Portfolio*. His *Letter on the Genius and Disposition of the French Government* (1809) was received with favor and went through four editions in England. In 1811 he instituted the *American Review*, the first quarterly in America, carrying it on for two years. He next published his *Correspondence with R. G. Harper respecting Russia*, which was followed by an *Essay on the Future State of Europe*. From 1817 to 1819 he edited the *American Republic*, and in the latter year appeared his *Appeal from the Judgments of Great Britain respecting the United States*. In 1821 he founded, in conjunction with Mr. Frye, the *National Gazette*, which shortly became a daily, and was enriched for 15 years with his genial articles on books, art and science. He was at the same time associate editor of the *American Magazine of Foreign Literature* (the precursor of the *Museum* and *Littell's Living Age*), but resigned his connection with it to resuscitate the *American Review*, which he conducted from 1827 till 1837. His contributions to the *Gazette* were issued separately under the title of *Didactics* (1837). In 1845 he was appointed U. S. consul at Paris, where he remained till his death on Feb. 7, 1859. While abroad he was a frequent correspondent to American periodicals, and contributed to Lieber's *Encyclopædia Americana* the articles on American biography.

His son, ROBERT MOYLAN WALSH (1811–1872), diplomat and litterateur, was born in Philadelphia, April 27, 1811, and was educated at William and Mary College. At the age of 19 he went to London as attaché to the American legation there, of which Washington Irving was secretary. He subsequently held various diplomatic appointments in different countries, and was for a long time a resident of Italy, where he held the positions of secretary of legation at Naples and U. S. consul at Leghorn. He returned to the United States in 1867, residing for a time in Philadelphia, and finally in Camden, N. J., where he died March 1, 1872. He inherited literary tastes from his father; contributed to the *Encyclopædia Americana*; translated some French books; and, in the intervals of his diplomatic engagements, assisted in editing the *National Gazette*. During his later years he contributed to *Lippincott's* and *Scribner's Magazines* and other periodicals.

His son, WILLIAM SHEPARD WALSH, litterateur, was born at Paris, Feb. 1, 1854. His boyhood was spent in Italy, but in 1867 he returned with his parents to the United States. He spent two years in Georgetown College, D. C., and thereafter studied law in Philadelphia, graduating in 1876 in the law department of the University of Pennsylvania. But his tastes, inherited from his father and grandfather, were essentially literary, and instead of entering on his profession he accepted the position of literary reader in the establishment of J. B. Lippincott Co., and in 1885 became editor of *Lippincott's Magazine*. Mr. Walsh, under the name of "William Shepard," has published several books, including *The Literary Life Series*, *Young Folks' History of the Roman Empire*, *Young Folks' Josephus*, and, under his own name, *Faust the Legend and Poem* (Phila., 1887), and *Paradoxes of a Philistine* (Phila., 1888). As a literary critic Mr. Walsh has few equals. His knowledge of books is exceptionally wide, his tastes catholic, and his judgment, matured by large experience, sound and unbiased.

WALTHER, CARL FERDINAND WILHELM, Lutheran theologian, was born at Langenschursdorf, Saxony, Oct. 25, 1811. He graduated at the University of Leipzig in 1833, and emigrated to the United States in 1838. He became in 1849 pastor of a Lutheran church in St. Louis and president of Concordia Seminary. By his ability and learning he took a prominent position among the Lutherans of the Western States. He endeavored to restore the confessional orthodoxy, and provoked a serious controversy as regards predestina-

tion. The Missouri Synod, under his direction, became a separate body, and it has been largely increased by immigration. Among his publications are *Die Evangelische Lutherische Kirche* (1867); *Amerianisch-Lutherische Evangelien-Postille* (1871); *A.-L. Pastoral Theologie* (1872); *Der Concordienformel Kern und Stern* (1877); *A.-L. Epistel-Postille* (1882).

WALTON, GEORGE (1740–1804), a signer of the Declaration of Independence, was born in Frederick co., Va., about 1740. He was first apprenticed to the carpenter's trade, and during his term acquired a fair education by private study. Subsequently he studied law in Georgia and was admitted to the bar, settling in Savannah for the practice of his profession in 1774. Walton, a patriot from the first, was one of four persons who called the first public meeting at Savannah for the purpose of concerting measures for resisting the aggressions of the crown and the defence of Georgia, and the resolutions adopted on that occasion were drawn up and largely suggested by him. In February, 1776, he was appointed a delegate to the Continental Congress, and as such signed the Declaration of Independence. He was re-elected in 1777 and signed also the Articles of Confederation. Being commissioned colonel of militia in December, 1778, he took part in the defence of Savannah, where he was dangerously wounded, and remained a prisoner till September, 1779. Next month he was chosen governor of Georgia, and again attained that dignity in 1789. He was four times a judge of the Superior Court of Georgia; was appointed delegate to the Philadelphia Constitutional Convention of 1787, but declined the office. In 1795 he was chosen U. S. Senator for one year. He died at Augusta, Ga., Feb. 2, 1804.

WALWORTH, REUBEN HYDE (1789–1857), jurist, was born at Bozrah, Conn., Oct. 26, 1789, and taken at the age of four to Hoosick, N. Y. At 16 he began to teach, and obtained 3 months' tuition in Latin and mathematics. Disabled a year later by an accident, he became a clerk in a country store and studied law. He was admitted to the bar in 1809, and entered on a successful practice at Plattsburgh. In the war of 1812 he was a major of militia and acting adjutant-general, serving as judge-advocate in two military trials, and taking part in the local operations of 1814. After the war Gov. Clinton commissioned him division judge-advocate, with the rank of colonel. He removed to Saratoga, was sent to Congress 1821, made circuit judge 1823, and chancellor of New York 1828. This position he held with great credit for 20 years. Many of his decisions are included in *Paige's & Barbour's Reports*, 1830–49, and those delivered in the Court of Errors, wherein he sat *ex-officio*, in the *Reports* of Wendell, Hill & Denio, 1829–50. His adjudications in MS. fill 39 folio volumes. His predecessor, Chancellor Kent, testified to his merit, and Story called him the greatest equity jurist living. In 1844 he was strongly recommended for the U. S. Supreme Court, and Pres. Tyler sent his name to the Senate, but it was withheld in the judiciary committee till that of Judge Nelson was substituted. The Court of Chancery was abolished by the Constitution of 1846, but Walworth's office and salary were continued a year longer. After withdrawing from the bench he confined himself to chamber practice, declining in 1847, and again in 1849, the headship of a committee to codify the laws of New York. He was a Presbyterian elder, first president of the State Temperance Society, 1829–43, and then president of the American Temperance Union, vice-president of the Bible and Tract Societies, and a member of the American Board of Commissioners for Foreign Missions. In 1832 he, with Dr. Nott and B. F. Butler, of New York, settled a dispute between Georgia and the U. S. Supreme Court. Walworth published *Rules and Orders of the Court of Chancery* (1829), and prepared the *Hyde Genealogy* (2 vols., 1864), said to be the most elaborate work of its kind at that time. He died at Saratoga, Nov. 21, 1857.

WAR OF 1812. This second war between Great Britain and the United States was declared, pursuant to Act of Congress, June 19, 1812, and continued 2 years and 9 months, being nominally terminated by the treaty of Ghent, Dec. 24, 1813, but actually ended, owing to delay in transmitting news, March 23, 1815.

Causes.—1. The seizure of U. S. seamen on board of U. S. vessels; ostensibly a right to apprehend deserters; but, in enforcement, so many sailors were forcibly taken as to cripple U. S. commerce, treating it like that of an enemy. (See SEARCH, RIGHT OF.)

2. Continued efforts of the U. S. government to obtain redress and guarantees against the repeated acts of aggression were fruitless.

3. When at war with other powers Great Britain claimed a right to make an extensive blockade beyond the actual local enforcements. This led to the capture of U. S. neutral vessels and goods and to the practical destruction of American commerce.

4. In time of peace a British 50-gun ship attacked the U. S. frigate Chesapeake, and the British sloop-of-war Little Belt fired into the U. S. frigate President.

5. The main and repeated acts of violence were the impressing of seamen. Six thousand cases of alleged impressment of U. S. citizens into the British service were recorded at Washington. When the war began 2500 such citizens had been committed to British prisons.

First Conflict.—When it was proclaimed there was in America little or no preparation for war. The frontier military posts were not even apprised. Some British merchants of New York promptly sent an express to Sir Isaac Brock, then commanding the Canadian troops, and he immediately sent orders to Capt. Roberts, his post-commander at St. Joseph's, to move at once against the nearest U. S. garrison which was kept on the island named Michilimacinae (now Mackinac). Capt. Roberts, adding volunteers and Indians to his regulars, amounting to 900, with two field-guns, embarked in boats the very day he received the orders. At 3 A. M., July 17, 1812, he landed at Michilimacinae and without delay took possession of a neighboring hill which dominated the fort, and there planted his artillery. Lieut. Porter Hanks, with a battery of 57 men, including officers and a few cannon, was holding the fort. At 11.30 A. M. Roberts sent in his demand for an unconditional surrender, with a threat of extermination if resisted. This proceeding was Lieut. Hanks' first intimation of a declaration of war. Hence surprised, outnumbered, and his works already dominated, the lieutenant surrendered without firing a shot. Thus the war commenced.

Campaigns of 1812.

The North-west.—Gen. Wm. Hull, a veteran of the Revolution, with 3000 raw troops, had marched into Michigan, crossed the Detroit River, and occupied Sandwich. Gen. Brock sent a force to Malden, which disturbed Hull's line of supply. Hull, on Aug. 4, detached Major Van Horn with 200 men to go to Raisin River in order to strengthen Capt. Brush's company of Ohio volunteers and help bring up provisions. A British Capt. Tallon with a few regulars, and Indians led by the famous Tecumseh, ambushed Van Horn *en route* near Brownstown. Van Horn was defeated, and retreated with a loss of 7 officers and 19 men, and the mail for Hull's army passed into the hands of the British.

In view of this defeat, Hull, on Aug. 8, recrossed the river and occupied Detroit, and then again undertook to reopen his communications southward, sending out Lieut.-Col. Miller with 600 men. This force encountered at the Magnaga some 400 British, including Canadians and Indians, led by Capt. Muir and Tecumseh, and gained a victory, yet Gen. Hull for some reason recalled the troops and so the fruits of Miller's victory

were lost. Gen. Hull's army had an out-post, near the site of Chicago, Fort Dearborn, commanded by Capt. Heald and garrisoned by about 50 soldiers; besides, there were present several civilians. Hull ordered the captain to evacuate the fort and join him, and Heald, relying for support upon some Indians, apparently friendly, commenced the march. He soon met an Indian ambuscade, and, after a severe battle, was compelled to surrender with an aggregate loss of 66 soldiers and citizens. The captain and his wife, both wounded, were set at liberty, made their way to a near British garrison and gave themselves up. This Fort Dearborn affair has been named "the massacre of Chicago."

The able British Gen. Brock, with regulars, volunteers, and Indians, not much exceeding Hull's army in numbers, followed up Hull's retreat and hemmed him in at Detroit. Hull refused the first summons to surrender, made Aug. 15; but when the hostile forces had drawn in closer to the fort and the artillery was preparing to open fire, the beleaguered general sent out a flag of truce and surrendered not only his army present, and the fort, but absent detachments and substantially the whole territory of Michigan. Fourteen hundred men, much cannon and provisions, were given up, and thus ingloriously the first campaign was closed.

The British general sent Maj. Muir with a detachment of regulars to assist the Indians that were massed under Tecumseh, in attacking Fort Wayne. The assault was planned for Sept. 1, 1812. Gen. W. H. Harrison, then in Ohio, hearing of the hostile movement pushed forward with a strong force to strengthen the garrison. But the major and the Indians, quickly apprised of his march, retired northward without a blow. Harrison reached the place Sept. 12. On the 3d the threats against Fort Wayne had already passed to the next frontier post, Fort Harrison, on the Wabash, and two young men in its neighborhood were killed and scalped. The next evening a suspicious company of Indians begged for admission. Capt. Zachary Taylor (afterwards General and President) was in command. That night Indians swarmed about the garrison; and a blockhouse close to the fort was set on fire. Taylor had less than 50 men, most of whom were sick in hospital, yet inspired by their captain all went to work to check the fire which spread to other buildings, to raise a temporary breastwork, and for eight hours to resist repeated assaults. For more than two days the little garrison held its own against overwhelming numbers. The Indians angered by this unexpected resistance brought cattle, horses, and hogs from the neighboring farms and slew them within sight of the garrison. At last, Sept. 5, 1812, the savages abandoned their fruitless efforts and left. Capt. Taylor and his soldiers received abundant thanks for their gallant defence.

The Indians, who were greatly excited and stimulated by the promises of the wily Tecumseh, made another attack on Fort Madison, which was situated not far from St. Louis, Mo. Some 200 Winnebagoes crept up to the fort, on the evening of Sept. 5, and slew a number of the garrison, found outside the fort. Lieut. Hamilton, thus warned, having a detachment of regular infantry, defended his fort against every expedient of the enemy, who used flaming arrows, burning fagots, and other means of firing the wooden roofs. Hamilton invented on the spot effective fire-extinguishers, made from gun-barrels. The conflict was kept up till 10 P. M. Sept. 7, when the Indians, despairing of success, raised the siege and fled.

The Central Department.—Turning now from the North-west department to the Central, the next battle of importance was that of Queenstown, Oct. 13, 1812. Gen. Van Rensselaer, with about 1200 troops, crossed the Niagara River and engaged a British force of about the same numbers made up of regulars, volunteers, and Indians. His command were nearly all killed or captured. Capt. (afterwards General) J. E. Wool and

Lieut.-Col. Winfield Scott (for whom see *ENCYCLOPEDIA BRITANNICA*) greatly distinguished themselves during this conflict. The British commander, Gen. Brock, was here slain. It was a remarkable incident that a large force on the American shore beheld their comrades in peril but refused absolutely to render them any assistance. This wretched conduct doubtless arose from an absurd opposition to fighting beyond the boundaries of New York. The Queenstown battle was well planned, but the means were inadequate to its execution. Before this battle, on Oct. 4, a skirmish occurred which gave a little relief from the mistakes and disasters of this department. A British force, perhaps 800 strong, under Col. Lethbridge, in boats approached Ogdensburg, which was defended by Gen. Jacob Brown, of the New York militia. He had about 1000 men. The British were stoutly met, defeated, and forced to withdraw to the Canadian shore. But not long after this success a similar British detachment here defeated 300 militia, and took possession of the town and fort. The attacking party lost about 60 men killed and wounded—the militia much less.

Campaigns of 1813.

Battle of Frenchtown.—Meanwhile in the North Gen. Harrison had been pushing his operations, aiming to recover Michigan. A portion of his army, which had not yet joined the main body, was leading the way northward under Gen. Winchester's command. Not far from Maumee Rapids the general received a despatch from Harrison warning him that the Indians were gathering in his front. Other messages of like nature reached him; but on Jan. 16, 1813, messengers from the Raisin River country came in haste and begged for help in behalf of the threatened settlements. Winchester, leaning to humanity, detached Col. Lewis with 550 men, and a few hours later Col. Allen with 110 more. These two parties united at Presque Isle (now Erie, Pa.). Near the Raisin River 100 British and 400 Indians with one cannon were in waiting. During Jan. 18 Lewis attacked the main position of his enemy strongly posted in Frenchtown, and succeeded in defeating both the regulars and Indians and then slowly drove them back till darkness ended the battle.

Raisin River Massacre.—During Jan. 19, as soon as Gen. Winchester heard of Lewis' success he brought up to Frenchtown all his force, except a small guard. A French settler reported to him that a hostile movement from Malden was on foot; yet the weather being exceedingly cold proper precautions against attack were neglected. About sunrise on the 22d Proctor with some 500 whites and 600 Indians sprang upon the general's lines. Notwithstanding the surprise the patriot soldiers for a time fought desperately, but the angry missiles seemed to come from every direction, so that the men became discouraged and gave way. Then followed the massacre of many prisoners and the compulsion of Gen. Winchester after his own capture to surrender a gallant remnant. The wounded were seldom spared and the little town was burned by the savages. This affair equals the Wyoming murders. Proctor was promoted for his success, yet fair-minded Americans and English condemned him for violating every rule of honor. Out of 1000 men Winchester lost 397 killed and missing, and 537 as prisoners of war. Proctor's loss, surprisingly small, was but 24 killed and 158 wounded. The terrible news produced, especially in Kentucky, profound grief and soon the most vigorous action; so that Gen. Harrison was speedily reinforced.

Siege of Fort Meigs.—At the Rapids of the Maumee Harrison established Fort Meigs. This was strategically excellent; it protected the country below, and was a starting-point to recover Michigan. Proctor, seeing this, soon started from Malden purposing to capture this fort. He took by water over 2000 mixed troops, Tecumseh leading the Indians. A couple of gunboats and some artillery aided his attempt. He

opened fire May 1, 1813, carefully drawing his cordon around the fort; whilst Harrison strengthened his work by every available contrivance. Happily, on May 4, he was largely reinforced. The incoming dislodged the besiegers, but met with great losses at the hands of Tecumseh owing to their too eager pursuit of fleeing Indians. Yet Proctor was speedily compelled to abandon the siege and withdraw. Harrison's important victory here was dearly purchased, over 800 being put *hors de combat*, while Proctor claimed that his loss did not exceed 100.

Naval Battle on Lake Erie.—The British naval commander, Barclay, had already managed to get, on Lake Erie near Malden, 6 war vessels into working order. At the same time for the United States Lieut. Elliott and later Commodore Perry were gathering and constructing quite a squadron (8 or 9 vessels) in the harbor of Presque Isle. Early on Sept. 10 Perry's squadron was anchored in Put-in Bay. Barclay made his appearance and a battle ensued. Perry, after long fighting and heavy loss, gained a decisive victory which filled the country with joy and hope.

Battle of the Thames.—Lake Erie being thus regained, Gen. Harrison hastened to bring up abreast the land operations. With the help of the navy he transferred his troops northward to a small island named the Eastern Sister, about 12 miles from Malden, Proctor's stronghold. Getting fairly ready, on Sept. 27 he pushed for Malden. Proctor, having destroyed his stores, had already fled to Sandwich, having with him Tecumseh and an army of perhaps 1800 whites and Indians. Gen. Harrison, leaving a guard at Amherst, sped on after him with his 3500 men. Col. Lewis Cass and Commodore Perry were Harrison's volunteer aides. Proctor again escaped at Sandwich, but after a swift pursuit was at last brought to bay near the Moravian Town (Orford, Canada West). He took up a strong position by the River Thames and accepted battle Oct. 5, 1813; he was badly defeated, and Tecumseh, who held out the longest, was slain. For this Proctor was court-martialled and disgraced, for alleged want of generalship. This battle of the Thames, added to Perry's victory, gave back to the United States the entire North-West.

The North-East.—Farther east a singular campaign was inaugurated. The Northern army, commanded by Gen. Wilkinson, was much scattered, the right under Gen. Hammond, at Plattsburg, the left under Gen. Boyd, near Niagara River, while Wilkinson retained the centre at Sackett's Harbor. Fifteen thousand men comprised the whole. The British opposing forces, extending from Niagara Falls through Kingston to Montreal, numbered about 8000. There was a remarkable parade about the proposed Canadian expedition. The war department itself left the capital and went to Sackett's Harbor. Gen. Armstrong, secretary of war, had been a high officer in the Revolution, and must take an active part. Combined movements were concocted, but, as one might anticipate, there was a confusion of counsels and cross-purposes.

At last in Canada an American brigade-commander, Gen. Izard, preceding one of the columns with his brigade, came upon a British force under Lieut.-Col. De Salberg in position near the Chateauguay and Outarde confluence. There were breastworks manned by at least 1000 men, some of whom were Indians. Gen. Izard drove in the pickets of De Salberg and then engaged the main body. He was progressing finely, when scattered firing and blowing of bugles (sent out by De Salberg) were heard from the woods near at hand. This ruse had such an effect upon Wade Hampton, the column commander, that he ordered an instant retreat. A second showy attempt against Montreal under the immediate charge of Gen. Wilkinson proved equally futile. The entire campaign was a sorry failure.

During the early part of 1813 Fort George, and York, Canada, were taken by the Americans. Gens.

Chandler and Winder led from Fort George some 1500 men to farther invade Canada. These were defeated and largely captured, the remnant fleeing back to Fort George for refuge. Some 600 Americans under Col. Buerstler were captured by the smaller force and suffered disgrace. The successful attack by a British detachment on Black Rock had its reprisal in a subsequent defeat at the hands of the American militia.

An instance of wanton destruction by Gen. McClure (U. S. army), who burned Newark, Canada, and then escaped to New York State in terror, marred the American record. The capture of Fort Niagara with its 400 by a night surprise from 600 British soon followed McClure's folly. Another British attempt on Black Rock succeeded; 1500 American militia were put to flight and Buffalo taken. So this Northern frontier work ended the year 1813, a prey to many fruitless conflicts.

Campaigns of 1814.

This irregular, ill-planned campaign was opened by Capt. Holmes, with 160 men, defeating 300 British at Longwood, Canada. A little after this, crossing Lake Ontario, the British seized Oswego, but lost heavily in an encounter that soon followed. Meanwhile the U. S. Gens. Brown and Scott busied themselves in the drills and discipline of new troops. Early in July they captured Fort Erie, and on the 4th Gen. Brown, with whites and Indians 3000 strong, had a brisk engagement, defeating Gen. Rial, commanding 2500 British, at Chippewa. Here Gen. Winfield Scott won a victory in a bayonet charge against English regulars.

Again the battle of Lundy's Lane (July 25, 1814) brought 3000 Americans against 3500 British. Scott made a harder fight than before, and was badly wounded. His successor drew off his men in the ensuing night. So the British Gen. Drummond, though dislodged and put to flight, soon returned and always claimed the victory. Drummond, unduly encouraged, then undertook the recapture of Fort Erie, Gen. Gaines commanding, but failed. Another small affair

occurred at Black Rock, where Col. Tucker attacked Major Morgan's 300 Americans. Morgan repelled the assailants with loss. On Sept. 17, after Gen. Brown's return to Fort Erie, he made a sally against the besiegers, now 4000 strong. Each army claimed the victory in this conflict, but the British gave up the field. Yet the American troops, on Nov. 5, were withdrawn from Canada.

An invasion of the United States farther east, from Lake Champlain to Plattsburg, N. Y., by Sir George Prevost with over 12,000 men, proved abortive. As soon as Com. McDonough had defeated the British fleet on the lake, Sir George, with the land troops, fled in much haste. Small portions of Maine were conquered by the British and held till peace. So much for operations in the North-east.

The Capture of Washington, D. C.—In the South during August the British, about 5000 in number, under Gen. Ross, came boldly up the Chesapeake and the Patuxent, and landing, marched via Bladensburg on Washington itself. Near Bladensburg Gen. Winder had gathered a small opposing force, and after a skirmish was soon dislodged by a British bayonet charge, having lost 26 killed and 50 wounded. Washington was taken and the public buildings burned. Gen. Ross at once drew back, but made a similar expedition in September, against Baltimore. There was a sharp battle at North Point which seemed favorable to the British; but Ross was killed and his losses were 288 killed and wounded. The American Gen. Stryker had 113 killed, wounded, and missing. At Washington and Baltimore, on the part of the U. S. government, there had been a shameful want of preparation. But the British fortunately were content with the damage inflicted, and did not follow up their boldness with any permanent advantage.

Naval Battles of the War—Besides those already described the naval actions were mainly duels between American and British vessels. The table shows the principal. (The star indicates the victorious vessel.)

Naval Battles of 1812-15.

Date.	U. S. Vessel.	Commander.	British Vessel.	Commander.
Aug. 13, 1812.....	Essex *	Cap. Porter.....	Alert.....	Cap. Langhorne.

June 23, 1815.....	President *	Com. Rodgers.....	Belvidere.....	Cap. Byron.

Jackson's Campaigns.—As a result of Tecumseh's influence among the Indians of the South-west, a large body went on the war-path and made a stand for battle at Tallushatchee settlement, situated on a branch of the Alabama River. Against them Gen. Andrew Jackson gathered a force of about 2500 men. He ordered his lieutenant, Gen. Coffee, to destroy the settlement. The latter, with 900 men, crossed the river, and having approached within 1½ mile of the village, organized his force into two columns and endeavored to encompass the enemy. Not succeeding in a surprise the expedient was tried of a small detachment retreating before the savages until the eager pursuers were brought under the fire of the main body: the Indians retreated to their families and are said to have "fought so long as they could stand or sit." One hundred and eighty-six Indians were killed in this engagement and 84 women and children taken

prisoners, while there were only 46 casualties in Coffee's command. This battle was fought Nov. 3, 1813. On Nov. 9, 1813, occurred the second battle, Talladega, under Gen. Jackson's direction. The loss of the Indians in this action was 299 killed, while the Americans' was but 15 killed and 80 wounded. On Nov. 18, while Gen. Jackson was negotiating with the Hilabee Indians, by some misunderstanding, detachments under Gens. Cocke and White attacked the Indians' village near the Tallapoosa River. The Indians, having plighted their faith to Jackson, were attacked and slaughtered without making resistance; 60 were killed and 256 captured, the assailants not losing a man. On Nov. 29 occurred the battle of Autossee. A small force of irregular troops under the immediate leadership of Gen. Floyd, of Georgia, massacred some 200 Indians. There was but faint resistance, Floyd's men suffering but little loss, viz., 11 killed, 54 wounded.

On Dec. 23 the next battle, Ecanachaca, was fought by Gen. Claiborne, who had a mixed force of whites and friendly Indians. The hostiles suffered a complete route, losing about 30 killed and their two villages of more than 200 houses burned. Claiborne's loss in the engagement was 1 killed and 6 wounded. In the next battle, that of Emuckfau, Jan. 22, 1814, it is difficult to tell the numbers engaged. Gen. Jackson was present in person and fell back to Fort Strother the day after the engagement. The Indians regarded this action as a victory for them and greatly disturbed his retreat. A heavy skirmish at Enotochopco was a part of this retreat, resulting in a great loss to the pursuers. Gen. Jackson was much incensed at his losses and at the appearance of defeat. He soon reorganized his force and set on foot another expedition of about 3000 whites, with a body of friendly Indian allies. On March 27, 1814, he fought the battles of Tohopaka or Horse-Shoe Bend, on the Tallapoosa.

Jackson's loss in the attack was 202 killed and wounded; the hostile Creeks lost 557 killed on the field and about 300 more killed while trying to cross the Tallapoosa; but few, if any, of those engaged in battle escaped death. It is said that there were about 300 women and children taken prisoners. Such is a specimen of Gen. Jackson's severe Indian warfare. This last terrible engagement broke the power of the Indians in the South and South-west.

The next time we meet Gen. Jackson is Dec. 2, 1814, at New Orleans. He gathered there such an army as he could, and made ready against a British force already reported approaching from the Gulf of Mexico. The latter was commanded by Sir Edward Pakenham, and numbered of all arms about 9500 men, including over 1000 seamen. Jackson's whole command did not exceed 3700 effectives, most of whom were raw levies. The entire conflict was embraced between Dec. 10, 1814, and Jan. 18, 1815. What is usually called the Battle of New Orleans took place on Jan. 8, being a British assault on Jackson's prepared lines, in which the assailants sacrificed nearly 3000 men and lost also their commander, Sir Edward Pakenham, and two other generals. Jackson's loss was very small, as he was fighting from behind breastworks. The treaty of peace between the United States and Great Britain had been agreed upon at Ghent, Belgium, nearly a month before this battle, but the fact was not known till long afterwards. (O. O. H.)

WARBLER. This name is given, with the necessary modifying terms, to a very great number of highly characteristic North American birds. In a wide sense all the great family of *Sylviolidae* may be called Warblers; but the name belongs specially to the sub-family *Sylviolinae*, which includes 10 recognized North American genera, namely: *Mniotilta*, the creeping warblers; *Parula*, with four or more beautiful species; *Protonotaria*, the swamp or prothonotary warblers; *Helminthus* and *Helminthophila*, the latter with 8 or more good species; *Penceltramus*, the olive warbler; the great genus *Dendraea*, the wood warblers of some 35 species, mostly North American and West Indian; *Sitta*, the wag-tail warblers; *Oporornis*, the bush warblers, and *Geothlypis*, the ground warblers. To the sub-family *Setophaginae* belong a few North American and many South American forms. Many of the warblers are exceedingly beautiful little birds, and they are all of them, as active insect-feeders, valuable friends to the farmer. Notwithstanding their name, only a few are specially gifted in song. They are closely allied to the Tanagers, and have certain affinities with the honey-creeper. Some of them simulate the *Tyrannidae*, especially in their habits; others seem to approach the nuthatches, the titlarks, the wrens, the titmice. Most later systematists group the *Icteriinae* or chats with the warblers; but upon doubtfully sufficient grounds. (C. W. O.)

WARD, ARTEMAS (1727-1800), general in the Revolutionary war, was born at Shrewsbury, Mass., Nov. 27, 1727. He graduated at Harvard College in 1748, and in 1755 became major in the regiment of Col. E. Williams, rising in Abercrombie's campaign against the French near Lake Champlain to the rank of a colonel. In 1774 he was elected a delegate to the provincial council of Massachusetts, and his military experience and high reputation secured his appointment as a general officer in October of that year. In the following May, when the Revolutionary war had begun, he was commander-in-chief of the Massachusetts forces. During the battle of Bunker's Hill he remained at his headquarters at Cambridge. In June, 1775, the Continental Congress placed him first on the list of major-generals, and, as such, he was commander-in-chief at the siege of Boston until the arrival of Washington, when he became his second, with headquarters at Roxbury, and had command of the right wing. He resigned in consequence of ill health in April, 1776—a month after the capture of Boston. In this year he was chief-justice of common for Worcester co., and in 1777 president of the Massachusetts executive council. For 16 years he was a member of the State Legislature of Massachusetts and its speaker in 1785, and from 1791 to 1795 he was member of Congress. He died at Shrewsbury, Oct. 28, 1800.

WARD, FREDERICK TOWNSEND (1831-1862), a soldier of fortune who won distinction in China, was born at Salem, Mass., and received his education in the public schools. He early developed a roving, adventurous, and military disposition and after serving with the French army in the Crimea, (where by some means he obtained a commission) was connected with the filibustering schemes of William Walker, and then wandered to Mexico. Making his way to China, he obtained the confidence of the government and the title of "admiral general," and rendered very eminent services in putting down the Tae-ping rebellion. His first exploit was the taking of Sunkiang after one unavailing attack. He was singularly useful in drilling and organizing the native troops; out of this poor material, despised by foreigners, he managed to evolve "the ever-victorious army," which was able to hold its own in the field against ten times its number of Tae-ping rebels, whom they defeated in several engagements and drove from the Yung River valley. Ward was brave, honorable, energetic, and possessed of great executive and soldierly ability; his career is comparable to that by which "Chinese" Gordon won his earliest fame. He deserved and gained the confidence and respect of the mandarins, who reported in his favor at Peking. His brilliant successes were cut short at the early age of 31, in an action at Tyki near Ningpo, Oct. 7, 1862. At Sunkiang, where his remains were interred, a shrine was erected to him, and semi-divine honors were paid there by the grateful Chinese for some years, if not to the present day. (See S. Welles Williams' *Middle Kingdom*, 1883.)

WARD, MARY AUGUSTA, English novelist, was born at Hobart, Tasmania, June 11, 1851. She is the eldest daughter of Thomas Arnold, fellow of the Royal University of Ireland, and granddaughter of the famous Dr. Thomas Arnold, of Rugby. She was married in 1872 to Thomas Humphry Ward, fellow of Brasenose College, Oxford, who has since edited a collection of *The English Poets* (4 vols.), and the twelfth edition of *Mens of the Time* (1884). Mrs. Ward resides in Oxford. Her first publications were a story for children, *Milly and Olly* (1880), and *Miss Bretherton* (1884), in which one of the characters is said to be modelled from the actress, Miss Mary Anderson. Much of her literary work had regard to foreign languages, in which she is well versed, witness her translation of *Amiel's Journal* (1885), to which she prefixed an introduction, and her papers on Continental literature in the *Quarterly Review* and other periodicals. She also wrote, for Smith and Wace's

Dictionary of Christian Biography, lives of the early Spanish saints, kings, etc. But all her former work, however preparatory in its nature, was eclipsed by her powerful delineation of modern spiritual unrest in *Robert Elsmere* (1888). The work needed not the elaborate criticism and answer by Mr. Gladstone in the *Contemporary Review* (June, 1888) to obtain almost instantaneously a wide reading. The plot of the story is slight, but the dramatic power is unusually great, and some of the characters are remarkably lifelike, while against others the criticism is made that they are rather impersonations of certain tendencies of thought than actual persons. The popularity of the work, however, is not due merely to its literary and artistic excellence, but also to its bold attempt to tear aside the veil which covers much contemporary skepticism. Its admirers pronounce it a revelation of facts and opinions which need to be declared, while others who deny its truth as a complete picture acknowledge the author's genius in compelling doubters and disbelievers to recognize themselves. In faithfulness in recording states of mind with which she does not agree she is comparable to George Eliot, and the purity of her motives is equally conceded by all critics. But the ideal religion which the work seems intended to proclaim is a mere ignis fatuus.

WARD, JOHN QUINCY ADAMS, one of America's most noted sculptors, was born at Urbana, Champaign co., Ohio, June 29, 1830. He spent about seven years in the studio of Henry K. Brown, and in 1857-58 he found employment in Washington in modelling busts of various prominent men. Since 1861 he has resided in New York, where he was elected a national academician in 1863. A bronze statuette, *The Freedman*, his first full-length figure, was executed in 1861, and won the admiration of the critics. *The Indian Hunter*, one of his best works, was first sketched out about 1857-8, and the sculptor subsequently went west to make further studies for this subject. The statue is in New York, where are also his *Shakespeare*; a colossal statue of Washington (1882); *The Pilgrim*; and some other works. He has executed a number of portrait statues, among them *Commodore Perry* (Newport, R. I.); *Gen. Reynolds*; one of the few good statues of Washington that we have (Newburyport, Mass.); and *Gen. Geo. H. Thomas* (Washington, D. C.), which ranks with the best equestrian statues produced in this country. He is also engaged on a statue of Henry Ward Beecher to be erected in Prospect Park, Brooklyn. His work is vigorous, characteristic, and original; it is, moreover, distinctively American in subject and spirit. (F. L. W.)

WARD, NATHANIEL (c. 1578-1653), author, was born at Haverhill, Suffolk, England, and educated at Emmanuel College, Cambridge. He practised law for some years, travelled on the continent of Europe, and had "distinguished associations." After holding a preachiership in London, he became rector of Standon Massey, in Essex, and was silenced by Archbishop Laud in 1633. Emigrating to Massachusetts, he was pastor at Agawam or Ipswich 1634-7, and bore a leading part in founding Haverhill in 1640. The General Court appointed him in 1638 to draw up a code, which was adopted in substance as the "Body of Liberties" 1641. That year he preached the election sermon, which Winthrop found rather classical than Biblical. His *Simple Cobbler of Agawam* (1647), written in Massachusetts, but published after his return to England, retains some reputation, and is praised by Prof. Tyler as "a medley of wit and humor," "the most eccentric and amusing" American book of the colonial era. It bore the name of "Theodore de la Guard," and was a satire on the politics, fashions, religious and other opinions of the age, marked by sincere bigotry and punning whimsicality. One of its queer statements is that "polypiety is the greatest impiety." Ward also put forth several pamphlets, preached before the House of

Commons June 30, 1647, became minister of Shenfield in Essex, and died there in 1653. J. W. Dean wrote a *Memoir* of him (Albany, 1868).

WARD, WILLIAM HAYES, editor, was born at Abington, Mass., June 25, 1835. He was educated at Phillips Academy, Andover, and at Amherst College, graduating in 1856. He studied theology in Union Theological Seminary and at Andover, graduating from the latter in 1859, and having in the meantime been tutor in Beloit College, Wis., for a year. He was pastor of a church at Oskaloosa, Kan., from 1859 to 1861, then became a teacher, and in 1865 was made professor of Latin in Ripon College, Wis. In 1868 began his connection with the *New York Independent*, of which he became superintending editor in 1871. Under his direction that journal has sought to foster genuine progress in theology and Christian union among all Evangelical denominations. It has also opened its columns to the representatives of all prominent movements, social and political, as well as religious. Dr. Ward has given special attention to Assyrian and Babylonian archæological studies, and he was director of the expedition to Babylonia, which was sent in 1884 at the expense of Miss Catharine L. Wolfe of New York city. He has contributed to the *Bibliotheca Sacra* and to the *Proceedings* of Oriental societies. With Mrs. Lanier he edited Sidney Lanier's *Poems* (1884).

WARE, HENRY (1764-1845), Unitarian theologian and controversialist, was born of poor parents on a farm at Sherborne, Mass., April 1, 1764, and assisted through Harvard by his brothers. After graduating in 1785, he taught for a time, and was ordained pastor at Hingham 1787. His election as Hollis professor of divinity at Harvard in 1805 opened the Unitarian controversy in New England, and caused the college to be given over by the orthodox. In 1816 Dr. Ware was made professor of Systematic Theology in the newly formed Divinity School. In 1839 he resigned his former chair in the college. He published *Letters to Trinitarians* (1820), an *Answer* (1822); and a *Postscript* (1823), in controversy with Dr. Leonard Woods, of Andover; *Inquiry into the Foundation, Evidences, and Truths of Religion* (2 vols., 1842), and some sermons. He died at Cambridge, July 12, 1845.

His son, HENRY WARE, JR. (1794-1843), also a theologian, was born at Hingham, Mass., April 21, 1794, graduated at Harvard 1812, and taught for two years at Phillips Academy, Andover. He was pastor of the Second Church in Boston 1817-29, having R. W. Emerson as colleague for the last year, and professor of pulpit eloquence and pastoral care at Cambridge 1829-42. He edited *The Christian Disciple* for some years from 1819, and contributed largely to periodicals. His poetical talents were early shown; a few of his hymns have been widely used. He published *Hints on Extemporaneous Preaching* (1824); *On the Formation of the Christian Character* (1831); a *Life of the Saviour* (1832); and *Scenes and Characters Illustrating Christian Truth* (2 vols., 1837). He died at Framingham, Mass., Sept. 22, 1843. An edition of his works in 4 vols. appeared 1846-7, and his *Memoir* by his brother, in 2 vols., 1846; the latter was surpassed in popularity by that of his wife, *Mary Lovell Ware* (1798-1849), by E. B. Hall, 1852.

His brother, WILLIAM WARE (1797-1852), the most brilliant of the family, was a Unitarian pastor in New York 1821-36, and won much reputation by his classical novels, *Zenobia* and *Aurelium*; these first appeared as *Letters from Palmyra* (1836-7); and *Probus* (1838). He also published *Julian* (1841); *Sketches of European Capitals* (1851); *Works and Genius of Washington Allston* (1852), and some sermons. His later years were spent mostly at Cambridge, where he died Feb. 19, 1852.

WARMING. See VENTILATION.

WARNER, CHARLES DUDLEY, author, was born Sept. 12, 1829, at Plainfield, Mass. On his father's death, the boy, then only five years old, went to live

with a relative at Charlemont. Here he remained till he was 13, as he tells in his *Being a Boy*, living the life of a typical farmer's boy, while his toils were lightened by a warm love for nature. In 1842 his mother removed to Cazenovia, N. Y., where he attended the Oneida Conference Seminary and was prepared for Hamilton College, where he graduated in 1851, taking the prize for the best English essay. He began to contribute to the *Knickerbocker*, and, soon thereafter, to *Putnam's Magazine*. Two years later he edited a *Book of Elegance*, which was published at Cazenovia, and then formed a plan for publishing a monthly magazine in Detroit. This unscarried, and he joined a surveying party on the Missouri frontier. Returning to New York city, he studied law, mainly in the Astor library, and in 1856 was admitted to the bar in Philadelphia, and practised in Chicago till 1860. He then became assistant-editor, and subsequently editor, of the Hartford (Conn.) *Press*, and soon went with the *Press* to the *Courant*, becoming assistant editor and part-proprietor. In 1868-9 he spent 14 months in Europe, and his *Saunterings* is the outcome of his tours there. His reputation began with the republication of a series of papers called *My Summer in a Garden* (1871). His later writings include *My Winter on the Nile*; *In the Levant*; *Washington Irving*; *A Roundabout Journey*; *Life of Captain John Smith*; *The American Newspaper*; *Mummies and Moslems*; and *Their Pilgrimage* (1886). In conjunction with S. L. Clemens ("Mark Twain") he also produced *The Gilded Age* in 1873. He resides in Hartford, Conn., and is one of the editors of *Harper's Magazine*. Warner belongs to the meditative school of literature, with a seasoning of humor and quaintness. His philosophical playfulness reminds us of Holmes, his quaintness suggests Lamb, and the placidity and purity of his style recall Washington Irving. "His works have a surface of smiles," says William A. Rideing, "but under the smiles lie deep thoughts."

WARNER, SETH (1743-1784), colonel in the Revolutionary war, was born at Roxbury, Conn., May 17, 1743, son of Dr. Benjamin Warner. From his youth up he was distinguished for his sound judgment, energy, and courage—moral as well as physical. In 1765, with his father, he removed to Bennington in the New Hampshire Grants (now Vermont), the territory being in dispute between the States of New York and New Hampshire. During the contest Warner and Ethan Allen (q. v.) were the leaders of the settlers on the "grants" and the champions of their rights, for which they were outlawed by the State of New York and a reward offered for their arrest. On the outbreak of the Revolutionary war Warner and Allen led the "Green Mountain Boys" to the capture of Ticonderoga, May 10, 1775, and on the next day Warner captured the important post of Crown Point with 113 cannon. Both were made colonels by the settlers and recognized as such by the army in the invasion of Canada. In the siege of St. John's (where Allen was captured) Col. Warner took part under Montgomery, and defeated Gen. Carleton in the attempt for its relief. When Ticonderoga, on the approach of the English under Burgoyne, was evacuated on the night of July 6, 1777, the main body of the American army took the road through Hubbardton and Castleton, Warner's regiment and another constituting the rear guard. When attacked next day by Gen. Frazer with the *élite* of the British army, Warner maintained a stubborn resistance till overwhelmed by Hessian reinforcements. Few actions in the war were more obstinately fought, and for his gallantry here and other services Warner was offered the rank of brigadier-general by Washington, but declined acceptance on the ground that his education did not qualify him for the position. At the battle of Bennington Col. Warner arrived too late to take part in the successful assault upon Baum's defences, yet in

season to repel the enemy's reinforcements advancing under Breyman and to share in the glory of the exploit. During the remainder of the campaign till Burgoyne's surrender Warner was constantly on the alert. For seventeen days he never took off his boots, and, in consequence, a disorder settled in his feet which proved incurable and disabled him for further service. He transferred his residence from Vermont back to his native Roxbury, and died there, Dec. 26, 1784. Col. Warner was of noble appearance, being 6 feet 2 inches in stature. His features were regular and indicative of mental strength and fixedness of purpose, and his manners at once pleasing and dignified.

WARNER, SUSAN (1818-1885), novelist and religious writer, was the daughter of a lawyer, who wrote some books of a political or patriotic character. Her earlier works, published under the name of "Elizabeth Wetherill," were very extensively circulated. *The Wide, Wide World* (1849) and *Queechy* (1852) were translated into French and German; of the former, meant for young girls, as were most of her books, 500,000 copies are said to have been sold in ten years. The French critic, Taine, read it and in his *History of English Literature* refers to it as a striking example that English and American novelists are "not artists but moralists. It is only in a Protestant country," he says, "that you will find a novel entirely occupied in describing the progress of moral sentiment in a child of twelve." But Miss Warner wrote books of other kinds. *American Female Patriotism*, a prize essay, appeared in 1852, and *The Law and the Testimony*, a compilation from Scripture, in 1853. Among her later fictions were *The Hills of the Shatemuc* (1856), *The Golden Ladder* (1862), *The Old Helmet* (1863), *Milbourne House* (1864), and *Daisy* (1868).

Her sister, ANNA WARNER, born in New York city, wrote originally under the name of "Amy Lothrop." *Dollars and Cents* appeared 1852, *My Brother's Keeper* (1855), *Stories of Vinegar Hill* (6 vols., 1871), *The Fourth Watch* (1872), *The Other Shore* (1873), and a small volume of *Wayfaring Hymns* (1869). Some of her translations from the German appeared without name in *Hymns of the Church Militant* (1858), which she compiled. In conjunction with her sister Susan she produced *Ellen Montgomery's Book-Shelf* (5 vols., 1853-9), *Say and Seal* (1860), which had a large sale, and *Wych Hazel* (1876), besides the *Word Series* (3 vols., 1868), and others of a religious character or intended for juvenile readers. The publications of the sisters were often in two volumes; the character was rather edifying than intellectual, and the earlier ones had the larger share both of literary merit and popular success. From about 1860 the sisters lived on Constitution Island in the Hudson, near West Point.

WARREN, GOUVERNEUR KEMBLE (1830-1882), general, was born at Cold Spring, N. Y., Jan. 8, 1830, and graduated at West Point in 1850. Assigned to the corps of topographical engineers, he was employed in surveys in the West, and was the first to explore the district of the Black Hills. For four years, 1854-58, he was engaged in the construction of a map of the trans-Mississippi region, and contributed to the *Pacific Railroad Reports, Explorations in the Dakota Country*, and other government publications. He was assistant professor of mathematics at West Point from 1859 to the beginning of the civil war, which he entered as lieutenant-colonel of a Zouave regiment, the Fifth N. Y. At Big Bethel he brought off the body of Lieut. Greble. Becoming colonel Aug. 31, he was for some time employed in the construction department at Washington. After serving before Yorktown, he was in May, 1862, placed in command of the Third brigade of Sykes' division of Porter's corps (the Fifth), at the extreme right of the forces. He was engaged in all the actions of that campaign, and at Gaines Mill, where he was slightly wounded, earned the brevet of lieutenant-colonel in the regular army and the commission of brigadier-general of volunteers. He went safely

through the battles of Malvern Hill and the second Bull Run, and at Antietam half his regiment were killed or wounded. He bore a part at Fredericksburg, and on Feb. 2, 1863, he became chief of topographical engineers on Gen. Hooker's staff, and June 8, chief engineer of the Army of the Potomac. In the midst of the war, June 17, he was married. On July 2 he held and defended Little Round Top, the key of the Union army's position at Gettysburg, where he received a slight wound. This was followed Aug. 8 by the commission of major-general of volunteers, dating from the battle of Chancellorsville, May 3. In August he had temporary command of the Second Corps, and in October repelled an attack by A. P. Hill at Bristow Station and received the brevet of brigadier general, with special praise from Gen. Meade. At Mine Run, Nov. 30, a movement was ordered by Meade which the changing circumstances of the field made impossible of execution without useless sacrifice of life; Warren in the exercise of a reasonable discretion disobeyed the order, and was sustained and commended by his superior officer for so doing. On March 24, 1864, when the army was being reorganized, he was placed in command of the Fifth Corps, which he led gallantly in the battles of the Wilderness, Cold Harbor, Petersburg, and minor engagements. His men trusted and loved him. Gen. Grant in his *Personal Memoirs* pronounces him "an officer of superior ability, quick perceptions, and personal courage to accomplish anything that could be done with a small command," but declares that his constitutional defect was an endeavor to superintend in person the execution of all his orders, and to guard against remote contingencies which his superior officer had probably otherwise provided for. At the outset of the campaign Grant thought of Warren as Meade's possible successor, but early in the next year Grant was so much dissatisfied with Warren's dilatory movements that he called Sheridan's attention to his serious defects and authorized him if Warren's "removal were necessary to success not to hesitate." On April 1, 1865, at Five Forks, Gen. Warren unfortunately ventured to exercise discretion as he had successfully done sixteen months before, but Gen. Sheridan, who had been impatiently waiting for Warren's arrival, at last sought him out and relieved him of his command. Being sent to Gen. Grant, he was put in command at Petersburg. This disgrace wounded Warren's spirit deeply and permanently; he afterwards defended his conduct in a pamphlet, but a court of inquiry sustained Sheridan. The brevet of major-general, bestowed "for gallant and meritorious services in the field," failed to console Warren, and public opinion was not inclined to meddle in a painful controversy between two officers of such eminence. The war was nearly over. After two weeks' service in the South-west he resigned his volunteer commission. He remained in the regular army, employed upon forts, harbors, bridges, etc., as a major of engineers. He died at Newport, R. I., Aug. 8, 1882.

WARREN, JOSEPH (1741-1775), a patriot of the American Revolution, the son of a farmer and descendant of an early settler at Boston, was born at Roxbury, June 11, 1741. After graduating at Harvard 1759, he studied medicine, and began to practise 1762, but zeal in the cause of liberty soon rendered him indifferent to bright prospects of professional advancement. The Stamp Act set him thinking, and his evenings were given to the study of the great questions then rising into prominence. By 1766 his opinions were formed, and they thenceforth ruled his actions; he gave himself heart and soul to American freedom, and labored with tongue and pen to bring others to his mind. He had every quality of a leader—popular manners, sweetness of temper, ready and vivid eloquence, intense energy, fearless ardor, and exquisite prudence. The plan for town meetings was drawn up in September, 1768, by Warren, Otis, and Samuel Adams. He was

active in the caucus which at first met secretly in private houses, but after 1773 in a hall, inviting the attendance and co-operation of workingmen. Dr. Warren and Samuel Adams, intimately associated throughout, were the brains and soul of the early movement in Massachusetts; of the two, Warren was the more conservative—the slower to abandon hope of a peaceful settlement which should secure colonial rights. Acting for the Committee of Correspondence, they drew up in November, 1772, the two statements of these rights and of the violations thereof a year later. Warren was one of the committee to prevent the landing of the tea. The "Solemn League and Covenant," to suspend commercial relations with England, sent to every town in the province in June, 1774, was reported by him to the Committee of Correspondence. The progress of events had by this time made him ready for extreme measures. He told the Suffolk County Convention in September that "a sovereign who breaks his compact with his people forfeits their allegiance," and wrote to Quincy in November that if recent acts were not repealed, the two countries had better separate. He personally handed to Gen. Gage papers protesting against the fortifications then being built around Boston. Toward the end of 1774 he was at the head both of the Provincial Congress and the Committee of Safety, and practically dictator, but for the British troops. His disinterestedness and wisdom made him the safest depository of power and executive of the popular will. He restrained the enthusiasts who would have precipitated a local conflict, and insisted that the colonies must act together through the Continental Congress. March 5, 1775, he was a second time the orator on the anniversary of the Boston massacre. The church was crowded, and he entered by a window. British officers sat on the pulpit stairs, and one of them, at some ringing sentence, displayed bullets in his open hand, which Warren at once covered with his handkerchief. This was improved into the story of a pistol levelled at the speaker's head. Soon after he, with Hancock and Samuel Adams, was, by order of the ministry, excluded from the pardon offered to other malcontents. His tireless vigilance penetrated the secret of the British movement on Lexington, and sent Paul Revere (*q. v.*) and Dana thither by different routes to warn Adams and Hancock, thus making possible the initial victory of the war. He was present at the fight, and was said to have had a lock of hair cut off by a bullet. He urged the appointment of Washington as commander-in-chief in place of Artemas Ward, whom some favored for local reasons. Declining the post of surgeon-general, he accepted from Massachusetts, June 14, that of major-general. The occupation of Bunker Hill, ordered by the Council of War, he thought unwise, but insisted on taking part in the action there. A colleague in the Committee of Safety strove to dissuade him from this step, saying it was death to go. He replied: "*Dulce et decorum est pro patria mori.*" Arrived at the hill, he refused to take command, saying he came as a volunteer to learn from older soldiers, and asked to be shown the place of greatest danger. He fell, "the last in the trenches," as the retreat began, June 17, 1775. His death was a awful loss to the colonies, but his example stimulated and cheered patriotic zeal everywhere. No American, from the founders to that date, had been more prominent or more useful than he; no life was ever more freely consecrated to liberty or more cheerfully laid down. In the presence of such a memory as Warren's, cold analysis gives way to grateful and reverent affection. At all points he was the model of a patriot hero. His zealous abilities would have taken high rank in the councils of the young republic; but the poetic beauty of his character seems fitly crowned by an early and glorious death. His body was not recovered for a year. Congress voted in September, 1777, to erect a monument, but the column raised by the Freemasons in 1794 was the first to mark the spot.

On June 17, 1857, the Bunker Hill Monument Association unveiled a statue of Warren with imposing ceremonies. See R. Frothingham's *Life and Times of Joseph Warren* (1865). (F. M. B.)

WASHBURNE, ELIHU BENJAMIN (1816-1887), diplomatist, was born at Livermore, Maine, Sept. 23, 1816, and passed an apprenticeship in the office of the *Kennebunk Journal*. In 1840 he removed to Illinois, and began to practise law at Galena. He was in Congress 1853-69—first as a Whig, then as a Republican. Of the latter party he was one of the organizers and leaders. He was chairman of the Committee on Commerce 1857-65, and of other committees, and was called the watch-dog of the Treasury. Though not acquainted with U. S. Grant till after the outbreak of the civil war, Washburne obtained for him a commission of brigadier-general in September, 1861, and was thenceforth his firm friend and efficient helper. On Grant's accession to the Presidency in 1869, Washburne became his Secretary of State, but held the post only a week, when he was sent as U. S. Minister to France. Here he won the greatest distinction of his life, and rendered conspicuous services to the cause of humanity. At the outbreak of war with Prussia in 1870, that government sought his protection for its citizens residing in Paris. He accepted the trust, and discharged it with rare tact, ability, and success. Respected and even trusted by the successive French authorities, he occupied a position of singular influence, and used it for the benefit of distressed and endangered foreigners. During the siege and the Commune, he was the only representative of foreign countries remaining, and the only person in Paris permitted to receive and send letters. By his means many Germans were enabled to communicate with their homes, or to pass thither in safety through the French lines, and to many others the horrors of that period were mitigated, though his efforts to save Darboy, the Archbishop of Paris, were fruitless. The gratitude of Germany for his services was often and warmly expressed. On leaving his post after eight years' tenure he went to Berlin to receive the public thanks of the Emperor. His later years were spent in Chicago. His *Recollections of a Minister to France*, 1869-77, appeared just before his death, which occurred Oct. 22, 1887.

Two of his brothers (all of whom spelt their name without the final e) were in Congress at the same time with himself, and otherwise attained distinction. ISRAEL WASHBURN, JR. (1813-83), was a representative from Maine 1851-60, governor 1861-63, and then collector at Portland. CADWALLADER GOLDEN WASHBURN (1818-82) emigrated to Wisconsin in 1841, was in Congress 1855-61 and 1868-72, entered the civil war as colonel, was a major-general of volunteers from 1862, governor of Wisconsin 1872-74, and a leading merchant in flour and lumber. Another brother, CHARLES AMES WASHBURN, born 1822, was an editor at San Francisco. He was sent in 1861 minister to Paraguay, where he had an eventful career, wrote a *History of Paraguay*, 1871, and invented the typograph and other instruments.

WATER MELON. See MELON.

WATER SUPPLY. Ever since cities were built and inhabited the question of water supply has engaged the attention of their people, and in early times fountains and springs were dedicated to the gods, who were supposed to keep them pure and undefiled; in ancient Rome the "Festival of Fontanalia" was annually kept, when fountains and wells were crowned with flowers and wreaths were cast upon the running streams. Aqueducts of wonderful magnitude, supported in some instances by three ranges of arches superposed, were built many centuries before the Christian era, and even at this day there may be seen similar grand conduits supplying the cities of the Old World. (See AQUEDUCTS.) In modern times

aqueducts depending upon gravity for the delivery of water have been superseded almost entirely by iron pipes, and where gravity is insufficient steam-power has taken its place, so that now we have the precious fluid not only bubbling and sparkling in our parks and fountains, but also brought to our very doors and delivered inside our dwellings. While we may boast of these modern inventions which the discoveries of the capabilities of steam and of iron have made possible, we yet fail to vie with the ancients in the purity or abundance of the water supplied to our great cities—Rome with its nine aqueducts was lavish in serving its people at the rate of over 300 gallons per diem for each man, woman, and child, while we are supposed to be contented with fifty.

The original source of all waters is found in the vast seas and oceans of the world, from whence it is drawn in perfect purity by the sun, and as vapor is wafted to the ends of the earth where, accumulating and condensing in clouds, it falls as rain or snow and finds its way back to the seas and oceans—thus completing its cycle after furnishing its life-giving properties to all living creatures and things. In the United States, as in other countries, it is collected, stored, and distributed by means of wells, cisterns, reservoirs, aqueducts, and pipes, the smaller cities depending upon wells and cisterns, and the more populous upon reservoirs which are supplied from rivers, streams, lakes, and springs. In some instances, as at Chicago, Ill., what is known as the "pump and stand-pipe" system is employed, and at others, as Kansas City, Mo., the "direct" or "Holly system" is in use—in these systems no storage or other reservoirs are required, as the water is pumped directly into the stand-pipe or into the mains and thence distributed through the city. "Driven-wells" are an American invention and consist in driving into the earth a hollow tube fitted with a strainer properly protected and shod with a wedge-shaped end; the tube is usually 1½ inches in diameter and of convenient lengths for driving; each length is screwed into its fellow as it descends, the thread of the screw being protected by a cap which receives the blows of the hammer. Successive lengths of tubing are added until satisfactory water is reached, which is discovered by means of a pump applied at the top from time to time. These tubes are driven to a surprising depth, 40 to 250 feet, and as they are virtually a continuous pipe reaching to the supply, no contamination from surface water is likely to occur if sunk deep enough. Of course they cannot penetrate rock, but where available are much thought of and are growing in favor. Brooklyn, N. Y., is probably the largest city in which they are extensively used.

It is now understood that water from shallow wells is wholly unfit for drink and should never be used for that purpose without boiling, filtering, and aerating. The water from deep wells depends for its purity upon the strata through which it percolates—chalk formations furnishing the best. Flowing artesian wells of great depth (one at St. Louis, Mo., is 3800 feet deep) are found in geological basins, and frequently furnish a wholesome water in large quantities which can be supplied without pumps or engines. (See ARTESIAN WELLS.) More than 2000 years ago the Chinese bored for water very much in the same manner that we do to-day, by percussive action. By the use of a tower or stand-pipe the water from wells may be utilized where the flow-pressure is not sufficient; but wells, like cisterns, cannot be depended upon to supply the growing needs of cities. A number of cities in the United States are supplied from springs, notably Huntsville, Ala., in the South, Salem, Mass., in the North, Grand Rapids, Mich., in the West, and in the far West quite a number are thus supplied; this is probably the purest source of supply, as springs are now regarded as furnishing more wholesome water than rain itself.

In order that the water supply may be constant and

See Vol. XXIV.
p. 402 (p. 429
Am. Rep.).

to guard against accident, it has been found necessary to provide storage; this is accomplished by means of reservoirs. (See **RESERVOIRS** in *ENCYCLOPÆDIA BRITANNICA*.) The capacity of these receptacles is determined by the needs of the city, and it is found best to provide a series of reservoirs, not only to meet any emergency that may arise but also for the purpose of permitting the water which has been pumped into the initial receptacle to settle in the additional ones before it is turned into the mains and pipes for distribution. Filtration is also employed to free the water of impurities, and many systems have been adopted for this purpose, one of the latest being a proposal by a New York company of a plan by which the filter beds are erected over the reservoir and the water is pumped into the beds, whence it percolates into the reservoir below. Another is known as the "Hyatt pure water filter," so arranged that the water is filtered after it leaves the reservoir and before its distribution. While the construction of reservoirs requires engineering skill, the location with reference to the surroundings is one that should engage the attention of the sanitarian. The water may become contaminated while stored from the proximity of the reservoir to the cultivated or inhabited lands which surround it, or from fungi or other foreign substances which may grow or be thrown or fall into it. The sides should be well protected, and if the ground rises above it, that should be sodded and kept free from everything contaminating and objectionable, such as swine, cattle, or other stock, etc. The rainfall is an important factor in deciding the quantity of water that may be obtained from whatever source; it is estimated that one-third of the rainfall disappears by evaporation and the absorption of vegetation, one-third descends into the earth to reappear as springs or remains as subterranean reservoirs that may be tapped by wells; and one-third flows as rivers and streams or forms lakes and pools.

While the question of cost ought not to have controlling weight where health is concerned, it is well in determining between different sources of supply to examine into the relative cost of subsidence, precipitation, filtration, etc., as applicable to the several sources under consideration, always bearing in mind that rivers or streams receiving sewage or refuse of manufactories within a limit of twelve miles are never a proper source of water supply whether chemical analysis or biological research develop the existence of impurities or not.

Referring to the question of a *pure water supply* and the difficulty of determining whether organic matter is present or not, Prof. J. W. Mallet, F. R. S., in an exhaustive paper upon water analysis prepared by him for the National Board of Health United States (see *N. B. H. Report*, 1882, p. 207), in which he takes the ground above indicated, sums up the result of different processes of water analysis conducted by himself and other experts in the following general conclusions:

1. It is not possible to decide absolutely upon the wholesomeness or unwholesomeness of drinking water by the mere use of any of the processes examined for the estimation of organic matter or its constituents.

2. I would even go further, and say that, in judging the sanitary character of a water, not only must such processes be used in connection with the investigation of other evidence of a more general sort, as to the source and history of the water, but should even be deemed of secondary importance in weighing the reasons for accepting or rejecting a water not manifestly unfit for drinking on other grounds.

3. There are no sound grounds on which to establish such general "standards of purity" as have been proposed, looking to exact amounts of organic carbon or nitrogen, "albuminoid ammonia," oxygen of permanganate consumed, etc., as permissible or not. Distinctions drawn by the application of such standards are arbitrary and may be misleading.

4. Two entirely legitimate directions seem to be open for the useful examination by chemical means of the organic constituents of drinking water, namely: first, the detection of very gross pollution, such as the contamination of the water of a well by accidental bursting or crushing of soil-

pipes, extensive leakage of drains, etc.; and secondly, the periodical examination of a water supply, as of a great city, in order that, the normal or usual character of the water having been previously ascertained, any suspicious changes which from time to time may occur shall be promptly detected and their causes investigated.

5. In connection with this latter application of water analysis, there seems to be no objection to the establishment of local "standards of purity" for drinking-water, based on sufficiently thorough examination of the water supply in its usual condition.

6. With the facts of this investigation before me, I am inclined to attach special and very great importance to a careful determination of the nitrites and nitrates in water to be used for drinking.

7. If I had intrusted to me the charge of watching a large city's water supply I should use all three of the principal processes for the examination of the organic matter present; each gives a certain amount of information which the others do not afford.

Under circumstances admitting only of the use of simpler means of investigation, the albuminoid-ammonia and permanganate processes might be employed together, but in no case should one only of these methods be resorted to, such a course entailing practically the neglect of carbon on the one hand or nitrogen on the other.

The Vienna Water Commissioners give the following rules for determining healthy water:

1. Water must be clear, sparkling, colorless.
2. It must contain but a small quantity of solid materials and be entirely free of organized matter (infusoria).
3. Of the alkaline earths (CaO, MgO) it must not contain more than 18 parts by weight in 100,000 parts by weight of water.
4. It must contain but a small fractional part by weight of soluble salts, particularly the sulphates and nitrates.
5. The solids held in solution and the temperature of the water must vary within very narrow limits during the year.
6. It must be protected from contamination.
7. The above requirements are fulfilled in many cases by soft spring water, which alone is suitable for drinking purposes.
8. The industries require water having nearly the same properties.
9. Filtered river water, if at all times free of turbidity, will answer for technical purposes, but on account of not fulfilling requirements 5 and 6, is not fit for drinking.
10. To sprinkle or clean streets any water is suitable provided it is odorless and does not contain a great amount of offensive material.

A survey of the water supply of the cities of the United States and the manner of securing it, etc., is too comprehensive to be given in detail here; for complete statistics upon this subject, embracing all necessary information and covering 1688 cities and towns, the reader is referred to the *Manual of American Water-Works* just published (1889) by the *Engineering News*, New York, to whose editors the writer is indebted for the table showing the supply, etc., of several of the principal cities. (See p. 762.)

The number of towns having a water-supply for domestic use in the United States and Canada up to Jan. 1, 1889, and their geographical distribution is here given:

New England—Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut.....	290
Middle—New York, New Jersey, Delaware, Pennsylvania, Maryland, District of Columbia.....	456
South Atlantic—Virginia, West Virginia, North Carolina, South Carolina, Georgia, and Florida	73
South Central—Alabama, Mississippi, Louisiana, Tennessee, Kentucky	57
North Central—Ohio, Indiana, Michigan, Illinois, Wisconsin.....	330
North Western—Iowa, Minnesota, Kansas, Nebraska, Dakota, Montana, Wyoming.....	222
South Western—Missouri, Arkansas, Texas, Colorado, New Mexico.....	130
Pacific—Washington, Oregon, California, Arizona, Nevada, Utah, Idaho.....	130
United States, Total.....	1688
Canada.....	78

Abstracted from the "Manual of American Water-Works," published by the "Engineering News," New York.

Town.	Population, 1880, est.	Constructed.	Capacity reservoirs, gallons.	Daily consumption, gallons.	Source of supply.	Mode of supply.	Pipe miles.	Pipe mains.	Service pipe.	Remarks.
New York city.	1,700,000	1744, 1799, 1843	18,385,000,000	110,000,000	Drainage area of Croton and Bronx Rivers, Schoharie, Schoenkill and Delaware Rivers and springs.	Gravity, with pumping to stand-pipe for high service. Pumping to reservoirs and direct.	620	Cast-iron.	Lead.	Wrought-iron and lead service.
Philadelphia, Pa.	1,000,000	1801	373,000,000	85,000,000	Surface-water from streams—open- and driven-wells.	Pumping to reservoirs.	876	"	"	"
Brooklyn, N. Y.	776,000	1859	1,180,000,000	46,000,000	Lake Michigan.	Direct pumping.	397	"	"	"
Chicago, Ill.	775,000	1854	None.	91,000,000	For 1886.	Pumping through stand-pipe and distribution system to reservoir.	638	"	"	"
St. Louis, Mo.	449,000	1867	60,000,000	31,000,000	Mississippi River.	Gravity, with pumping for high service.	314	"	"	Cast-iron, wrought-iron, and cement mains. Includes Chelsea, Everett, and Sumerville.
Boston, Mass.	400,000	1632, 1796, 1843, 1864, 1878	5,378,000,000	37,000,000	Lake Cochichewick, Sudbury River, and Mystic Lake.	Gravity, with pumping for high service.	564	"	"	"
Baltimore, Md.	400,000	1807, 1863	Estimated	34,000,000	Johns Falls and Gunpowder River.	Gravity, with pumping for high service.	338	"	"	"
Cincinnati, Ohio.	275,000	1820	1,000,000,000	32,000,000	Ohio River.	Pumping to reservoir and tank.	247	"	"	"
San Francisco, Cal.	250,000	1839	At least	19,000,000	Mountain streams.	Gravity, with a little pumping to reservoir.	260	"	"	"
New Orleans, La.	223,000	1833	4,500,000	6,000,000	Mississippi River.	Pumping to reservoir, stand-pipe, and direct.	72	"	"	"
Cleveland, Ohio.	220,000	1856, 1874	124,000,000	22,000,000	Lake Erie.	Pumping to reservoir.	252	"	"	Galvanized-iron and lead service. Owned by U. S. government. Includes Georgetown, D. C.
Washington, D. C.	200,000	1839	About	26,000,000	Potomac River.	Gravity, with pumping to reservoir and direct for high service.	128	"	Galv. iron.	"
Pittsburg, Pa.	213,000	1826, 1844, 1878	63,000,000	30,000,000	Allegheny River.	Pumping to reservoir.	175	"	Lead.	"
Buffalo, N. Y.	250,000	1839	14,000,000	38,000,000	Niagara River.	Pumping to reservoir and direct.	250	"	"	"
Newark, N. J.	160,000	1800, 1867	45,000,000	13,000,000	Passaic River.	Pumping to reservoir.	161	"	"	Galvanized-iron and lead service. Owned by city and a company.
Louisville, Ky.	165,000	1860	110,000,000	10,000,000	Ohio River.	Pumping to reservoir.	137	"	"	"

The largest system in the United States is in New York city, with an estimated population of 1,700,000 and daily consumption of 110,000,000 gallons, and with reservoir capacity of 18,385,000,000 gallons. With its new aqueduct it will have a daily supply of 500,000,000 gallons. The smallest system is at Drewsville, N. H., with a population of 90 souls. It has a gravity supply without reservoir, and

the daily consumption is unrestricted in amount. The great cities of New York, Brooklyn, Philadelphia, and Chicago are contemplating increasing their supply to meet their increasing wants. Philadelphia will more than double hers within a year, and when the third section of the East Park reservoir is completed the storage capacity will be 900,000,000 gallons. Chicago has Lake Michigan at its feet, and it is only a question of duplicating its present method or otherwise providing for furnishing an abundant supply. New York has sufficient water for the present in its supply from Croton and Bronx rivers, but its aqueducts are too small and are now being enlarged and increased. A proposition has been made by John R. Bartlett and associates of New York and New Jersey to furnish New York city, independent of the Croton water-shed, an ample quantity of pure and wholesome water from the lake regions of New Jersey. This proposition contemplates supplying Montclair, Newark, Jersey City, and surrounding towns in New Jersey, as well as New York city and Brooklyn, the plan being to collect all the available waters in the Passaic water-shed, including Greenwood Lake, and storing them in convenient reservoirs. These waters will then be conducted in pipes or in a permanently constructed aqueduct to the Jersey City shore of the Hudson River; tunnelling the river, the water will be delivered in the lower portion of New York city with a head-pressure of at least 300 ft. It will also be conducted across to Brooklyn in the same manner. It is claimed that by this combination plan all interstate questions can be avoided and riparian rights protected, and in addition there will be ample quantities provided for all the cities and towns of New Jersey that are dependent on the Passaic water-shed for their supply. The tunnel from Jersey City to New York is over one-third completed and can be finished in two years. The advantage of a double source of supply for New York city in case of war or serious accident to its present sources requires no argument.

The water supply of cities and towns, it is now generally believed by sanitarians, ought to be placed under the supervision of an intelligent board of health and furnished by a responsible company instead of owned and operated by the city. A properly constituted board to watch and investigate the condition of the water from time to time, and a company which could be held responsible for the quality and quantity of the water furnished, would be a great step in securing a wholesome and abundant supply of uncontaminated water. It is claimed that the system which prevails in many of our large cities, whereby the city water-works are made a means for political preferment instead of a source of comfort to its inhabitants, soon becomes a power for evil almost incalculable. (P. H. B.)

WATSON, ELKANAH (1758-1842), author and promoter of internal improvements, was born at Plymouth, Mass., Jan. 22, 1758, and apprenticed at 15 to a merchant of Providence, R. I. In 1779 he was sent to Southern ports to purchase cargoes for European shipment. His notes give historically valuable descriptions of Charleston and other towns. In 1779 he carried despatches to Franklin in France, engaged in business at Havre, and suffered reverses in 1782. His account of a *Tour in Holland* in 1784 was published at Worcester, Mass., 1790. After 4 years in North Carolina, he settled at Albany in 1789, and soon after examined the Mohawk valley with reference to a canal, and urged the project upon Gen. Schuyler and the legislature. A *Vindication* of Watson's claim to paternity for the idea, by R. Troup, appeared at Geneva in 1821. A canal company was incorporated in 1792, though nothing was really done till much later. Watson showed equal energy and public spirit in furthering river navigation, routes of land travel, and public education. His home was at Albany till 1807, then at Pittsfield, Mass., till 1816, when he returned to Albany. At both places he founded agricultural

societies; of these he wrote a history, published 1820. His *History of the Western Canals* appeared the same year. After a journey to the lakes and down the St. Lawrence, in the interest of internal navigation, he removed to Port Kent, N. Y., in 1828, and died there Dec. 5, 1842. *Men and Times of the Revolution*, taken from his journals and correspondence, and edited by his son, appeared 1855. Both by his writings and by the enterprises which he forwarded, and for which he did much to prepare the way, Watson made contributions to American history. His remarkable predictions made in 1815 in regard to the increase of population in the United States down to 1900 are commented upon by Prof. Francis A. Walker in the article on the UNITED STATES in the *ENCYCLOPÆDIA BRITANNICA*.

WATSON, JAMES CRAIG (1838-1880), astronomer, was born in Elgin county, Ontario, Canada, Jan. 28, 1838. His parents, however, were citizens of the United States, and he was soon taken to Michigan. He graduated at the University of Michigan, Ann Arbor, in 1857, and for the next two years was assistant there in the Observatory. He acted as professor of astronomy during the absence of Prof. Brünnow till 1860, and then as professor of physics till 1863, when he took permanently the chair of astronomy in the University and directorship of the Observatory, which he relinquished 1879 to accept same positions in the University of Wisconsin. He died at Madison, Nov. 23, 1880. He was one of the most distinguished American astronomers. In his 19th year, on April 29, 1856, he discovered a comet, and his computation of the orbit of the comet of 1858 (Donati's) is considered authoritative. He was thrice deputed by the U. S. government to observe solar eclipses—in 1869 to Iowa, in 1870 to Sicily, and in 1878 to Wyoming—and in 1874 to Peking, China, to observe the transit of Venus. His original planetary discoveries amount to 23. He was a member of the National Academy of Science, and other learned bodies. He received the degree of Ph. D. from the University of Leipzig 1870 and from Yale College 1871, and the degree of LL. D. from Columbia College in 1877. The Lalande gold medal was awarded to him by the French Academy of Sciences in 1870 for the discovery of six new planets in one year. He was for some years actuary of Michigan Mutual Life Insurance Company. His considerable fortune he willed to the National Academy of Science. His genius was that of originality, though he claimed it not. His intuitions escaped "the ordinary processes of calculation, and gave him a masterly command of mathematical logic and formulae." His work, *Theoretical Astronomy* (Phila., 1869), was at once accepted as a text-book at Leipzig, Paris, and Greenwich. His literary contributions are in *American Journal of Science*, Brünnow's *Astronomical Notices*, Gould's *Astronomical Journal*, and foreign astronomical periodicals. He published also *Popular Treatise on Comets* (Phila., 1860); *Report on Horological Instruments*, to the Centennial Exposition (1876), and *Tables for the Calculation of Simple and Compound Interest* (1878). (J. W. W.)

WATTERSON, HENRY, journalist, was born at Washington, D. C., Feb. 16, 1840, his father, the Hon. Harvey M. Watterson, being then a Democratic representative in Congress from Tennessee. On account of his defective eyesight young Watterson was educated chiefly by tutors at home. At a very early age he became dramatic and literary critic for the *States*, a Washington journal. At the age of 18 he became editor of the *Washington Democratic Review*, but in 1861 he returned to Tennessee to assume the editorship of *The Republican Banner* at Nashville. Shortly after the commencement of the civil war he entered the Confederate service, remaining in it till the close of the struggle with the exception of one year, during which he edited the *Chattanooga Rebel*. At the end of the war he returned to Nashville and revived *The Republican Banner*, and then removed to

Louisville to undertake the editorship of the *Louisville Journal*, in which he had purchased an interest. In 1868 this paper was consolidated with two others into the *Courier-Journal*, of which he continues to be editor. It has become one of the foremost organs of the Democratic party in the South. Mr. Watterson was temporary chairman of the National Democratic Convention of 1876, and he was a member of Congress from August, 1876, to March, 1877. He is an able political writer, a brilliant and incisive orator, and an uncompromising advocate of free trade.

WAYLAND, FRANCIS (1796-1865), president of Brown University, was born in New York city, March 11, 1796. His parents, who were of English birth, removed to Poughkeepsie, N. Y., in 1807. He graduated at Union College 1815, studied medicine and divinity, entered the Baptist ministry, and was a tutor at his *alma mater* 1817-21. For the next five years he held a charge in Boston, and there won great reputation by a sermon on *The Moral Dignity of the Missionary Enterprise* (1823), and two on *The Duties of an American Citizen*. In 1826 he returned to Union College as professor of mathematics and natural philosophy, but left it in February, 1827, for the presidency of Brown University, which he held for 28 years with distinguished success. He anticipated some of the chief educational reforms of our day in his *Thoughts on the Present Collegiate System in the United States* (1842), which favored a freer and more practical curriculum for students of non-professional aims. His *Report* for 1850 shows that these views had to some extent been embodied in changes of the course of studies at Brown the preceding year. As a maker of text-books (which embodied his class lectures) he stood in the front rank. Of his *Elements of Moral Science* (1835) 90,000 copies had been sold in 1868, besides sundry editions in England, and translations into foreign languages. His *Political Economy* (1837) attained a circulation about half as great. Both these were used in the Sandwich Islands in a native version. His *Intellectual Philosophy* (1854) was less successful but is still in the market. Dr. Wayland retained his eminence as a preacher and published *Sermons* (3 vols., 1833, 1849, and 1858), besides *Salvation by Christ* (1859), and *Notes on the Principles and Practices of the Baptist Churches* (1857), the last being reprinted from the *N. Y. Examiner*. He was easily the leader of his denomination in America. Among his other works are *Limitations of Human Responsibility* (1838); *Letters on the Ministry* (1863), and memoirs of Harriet Ware (1850), Dr. A. Judson (1853), and Dr. Chalmers (1864). He was very active in the cause of free libraries and public schools in and beyond his own State; he founded the American Institute of Instruction, and was long its president; and he did much for prison reform and other benevolent enterprises. Concerning slavery his position was early and clearly defined; a correspondence between him and Dr. Richard Fuller (q. v.), of Beaufort, S. C., appeared in 1845. He resigned the presidency of Brown in 1855, but continued to preach and write. He died at Providence, Sept. 30, 1865. See *Memoir* by his sons (2 vols., 1869).

WAYNE, ANTHONY (1745-1796), general, was born Jan. 1, 1745, in Chester co., Pa. His grandfather and father had seen service and his own youthful inclinations were strongly military. He was sent to school in Philadelphia, became a surveyor, and spent a year, 1765-66, in Nova Scotia. He was a member of the Pennsylvania provincial legislature in 1774 and of the Committee of Safety in 1775. Soon after he raised a regiment, was commissioned colonel in January, 1776, and sent in April to Canada. At Three Rivers, in June, he distinguished himself and was wounded. He had command at Ticonderoga for six months, was made brigadier-general May 21, 1777, and joined Washington in New Jersey. He rendered efficient service at the Brandywine, Sept. 11; having

command of the left wing, he opposed the passage of the British throughout the day, and led his men safely off at evening. On the 16th an action which he commenced was cut short by a storm. On the 20th he was surprised at Parker's Ferry and forced to retreat with some loss: he demanded a court-martial, which honorably acquitted him. In the battle of Germantown, Oct. 4, he commanded the right wing, but mistakes or accidents occurred, and he retreated with no new laurels. In the following months he was of much service in foraging, crossing into New Jersey and procuring cattle and provisions for the army. At Monmouth, June 28, 1778, he bore a prominent part and was praised by Washington. His most brilliant exploit was the storming of Stony Point, N. Y., July 15, at night, only bayonets being used; for this he received the thanks of Congress and a gold medal. His popular title was "mad Anthony." Fortune favored him with no more such opportunities as this. He suppressed a mutiny of Pennsylvania troops in New Jersey in January, 1781. At Green Spring, Va., July 6, he suddenly encountered the enemy and retired: accounts of this affair are conflicting. After Cornwallis' surrender he was sent to Georgia, where he cleared the State (except Savannah) of the enemy; the Legislature voted him thanks and a farm, on which he lived for some years. Whatever his degree of prudence, his gallantry had earned more than the brevet of major-general. He was a member of the Pennsylvania convention which ratified the constitution in 1789, and in 1791 claimed a seat in Congress from Georgia, but lost it. In April, 1792, he succeeded St. Clair in the command of the Western army in Ohio, which sadly needed recruits, supplies, organization, and discipline. After two years of preparation and negotiation he attacked the Indians at Maumee Rapids, Aug. 20, 1794, and won a brilliant victory; the treaty of Greenville was made the following year. Wayne was returning to the East when he died at Presque Isle, on Lake Erie, Dec. 15, 1796. His remains were interred at Radnor, Pa., and there a monument was erected by the Society of the Cincinnati, July 4, 1809. H. N. Moore published a memoir of him (1845). (F. M. B.)

WEED, THURLOW (1797–1882), journalist and politician, was born at Acra, Greene co., N. Y., Nov. 15, 1797. He had no early advantages but such as come from the discipline of hardship; he was a cabin boy on the Hudson at 10, and began to learn the printer's trade at 12. From one office he moved to another, and in the war of 1812 he served on the frontier. At 20 he was editing the *Agriculturalist* at Norwich, N. Y. From this time he was always connected with some newspaper. In 1826 he was sent to the Legislature, and as editor of the *Anti-Masonic Inquirer* at Rochester took part in the agitation of that time (stirred up by the Morgan murder), and helped to re-elect De Witt Clinton to the governorship. In 1830 he was again in the Legislature and placed in charge of the Albany *Evening Journal*, then started by the party opposed to "the Regency" and to Pres. Jackson. His life for the next 32 years was bound up with this paper and with New York politics, in which he became a mighty power. He was a master of the art of handling voters and managing conventions; he was said to have once turned a State election at the last moment by the dexterous use of a moderate sum. Yet he was personally incorruptible and disinterested; he neither sought nor accepted office for himself; he was loyal to his party and his country and so indifferent to his own fortunes that friends looked after his financial affairs with eminent success. With Seward and Greeley he constituted a State triumvirate. While the former was governor, 1839–43, Weed was considered by many a power behind the throne. Though New York was especially his province, he did not neglect national affairs, but assisted in nominating successively Harrison, Taylor, and Scott. His zeal for the Whig party was transferred to the Republican; he strove to make

Seward a presidential candidate in 1856 and 1860, but, mastering his disappointment, earnestly supported Fremont and Lincoln. The latter sent him to Europe on an unacknowledged mission in the autumn of 1861, and the next year he ceased to conduct the *Journal*. Removing to New York in 1865, he edited the *Commercial Advertiser* for three years. After that, his activity, though continued, was concealed: a new race of managers had arisen, and at Saratoga in 1876 he was warned to abstain from interference. He published *Letters from Europe and the West Indies* (1866), and contributed some *Reminiscences* to the *Atlantic Monthly* in 1870. In his old age his sight almost totally failed. He died in New York, Nov. 22, 1882, leaving an *Autobiography*, which was edited by his daughter, and appeared at Boston 1883 (2 vols.). To this was added in 1884 a *Memoir* by his grandson, T. W. Barnes. (F. M. B.)

WEEVIL. See AGRICULTURE, Chap. IX.

WEIR, ROBERT WALTER, artist, was born at New Rochelle, N. Y., June 18, 1803. He was engaged in mercantile pursuits until nearly twenty years of age, and then adopted art as a profession, studying under Jarvis, and painting for some time in New York. About 1824 he went to Italy, where he remained for several years. In 1828 he became an associate of the National Academy, and in 1829 he was elected an academician. Three years later he was appointed professor of drawing in the West Point Military Academy, a position which he held for 42 years. His works include portraits, genre pictures, and historical compositions, and he is noted especially for the faithful rendering of the accessories, the still-life in his pictures. Among his best-known paintings are *The Belle of the Carnival* (1836); *Landing of Henry Hudson* (1842); *Embarkation of the Pilgrims* (1845), in the rotunda of the Capitol, Washington; *The Evening of the Crucifixion* (1867); *Christ in the Garden* (1873); *Our Lord on the Mount of Olives* (1877); *Columbus before the Council of Salamanca* (1884), and various portraits, including one of Red Jacket, painted for Dr. J. W. Francis.

His sons have also gained an honorable position among our artists. JOHN FERGUSON WEIR, born at West Point, N. Y., Aug. 28, 1841, studied under his father. In 1861 he opened a studio in New York, where he became a National Academician in 1866. After spending a year in Europe he was, in 1869, appointed director of the Yale School of Fine Arts. He was also appointed judge of the fine arts at the Philadelphia Exhibition in 1876. His vigorous style is perhaps best shown by such strong work as *Forging the Shaft* (1868), which was burned, but of which a replica was exhibited at Paris in 1878. He has painted also portraits of S. Wells Williams and others, and in 1884 executed a statue of Benjamin Silliman.

JULIAN ALDEN WEIR, born Aug. 30, 1852, at West Point, N. Y., also studied under his father, and later (1872–76), under Gérôme, in Paris. He was elected a National Academician in 1886, was one of the founders of the Society of American Artists, and is also a member of various other societies. His works include Breton Interior and various other Breton subjects; *The Good Samaritan* (1881); and portraits of R. W. Weir (1880); Olin L. Warner (1881); Richard Grant White (1883); Peter Cooper (1884); and John Gilbert (1888). He has been the recipient of various honors at home and abroad, notably honorable mention at the Salon of 1881 for his portrait of Warren Delano, and the prize at the 4th Prize Fund Exhibition of the American Art Association, New York, for his *Idle Hours*. (F. L. W.)

WELLES, GIDEON (1802–1878), statesman, was born at Glastonbury, Conn., July 1, 1802, being descended from Thomas Welles, a colonial governor. He was educated at Norwich University, studied law and in 1826 became editor and proprietor of the *Hartford Times*, in which he advocated the election of

Gen. Jackson to the Presidency. He entered the State Legislature in 1827 and served there for eight years. In 1836 he was made postmaster of Hartford and soon after gave up the management of his newspaper, though he continued to be an active contributor to the press. In 1842 he was made State comptroller. From 1846 to 1849 he was in Washington as chief of a bureau in the navy department. During the Kansas-Nebraska troubles Welles, who had heretofore been an ardent Democrat, opposed the extension of slavery and when the Republican party was formed was one of its earliest adherents. As chairman of the Connecticut delegation to the Chicago convention, in 1860, he contributed to the nomination of Lincoln to the Presidency and was called by the latter to be his secretary of the navy. The civil war greatly enlarged the scope and duties of this department, but Secretary Welles conducted it with unflagging zeal, industry, and efficiency. He maintained along 2000 miles of coast a blockade as effective as the circumstances would permit, organized on the Mississippi River a fleet of ironclads and transports, sent out well-equipped expeditions to various points, and in various ways contributed to the numerous victories which added to the renown of the American navy. After the war was over, Welles remained in Pres. Johnson's cabinet, and supported his policy of reconstructing the Southern States, thereby losing favor with the Republican party. After his retirement he published "Memoirs of the War" in the *Galaxy*. He died at Hartford, Feb. 11, 1878.

WELLESLEY COLLEGE, a noted institution for the higher education of women, is in the beautiful village of Wellesley, Norfolk co., Mass., about 15 miles west of Boston. It was founded by Mr. Henry F. Durant, who in 1855 purchased here 300 acres of land, which he improved as a park. In 1875 the college hall, which had been carefully built under his supervision, was opened. It is 475 feet long and 150 feet wide at the wings. It is built of brick with free-stone trimmings, and is four stories high, but in some parts a fifth story is added, which serves as a studio and museum. Besides this building there are now a College of Music, Waban Cottage, Simpson Cottage, Stone Hall, Norumbega, Freeman Cottage. Wellesley has valuable collections of paintings and statuary, which are distributed through the rooms and halls. The library has 25,000 volumes. There are chemical, physical, biological and botanical laboratories, and the rooms used for scientific work have their appropriate collections of books. The college gymnasium was fitted up under the direction of Dr. Dudley A. Sargent, of Harvard University. Adjoining the college grounds is Lake Waban, on which 14 boats are used in summer. Entertainment in winter is furnished by concerts and lectures. The course of study is similar to that pursued in American colleges, but special opportunity is given for the study of art and music. Care of the rooms and halls is required of the students, who thus are taught the art of housekeeping, though they do not perform heavy work. At the opening of the college in 1875, provision had been made for 300 students, but 314 were enrolled in the first year. There were then 28 instructors and officers, Miss Alice E. Freeman being the president. She retired from this position in 1888 on her marriage to Prof. F. Palmer, of Harvard University. There are now 75 instructors. The first graduating class numbered 18 and that of 1888 numbered 60. The total number of students enrolled exceeds 2300, and the graduates 300. Besides Mr. and Mrs. Henry F. Durant, the principal benefactors of the college have been Mr. M. H. Simpson, Mrs. Valeria G. Stone, and George Smith.

WELLHAUSEN, JULIUS, German theologian, was born at Hameln-on-the-Weser, May 14, 1844. He was educated at Göttingen under Ewald, and there began to lecture on theology in 1870. He was made ordinary professor at Greifswald in 1872, but resigned in 1882 on account of his divergence from Protestant

theology. He then entered the philosophical faculty at Halle, and in 1885 accepted a similar position at Marburg. Among his publications are *Text der Bücher Samuels* (1871); *Pharisäer und Sadducäer* (1874); *Prolegomena zur Geschichte Israels* (1878); *Skizzen und Vorarbeiten* (2 vols., 1884-85). Wellhausen has been the most prominent advocate and exponent of the reconstruction of the history of Israel by higher criticism of the Old Testament. He wrote the article on "Israel" and other articles in the *ENCYCLOPÆDIA BRITANNICA*.

WELLS. See ARTESIAN WELLS and WATER SUPPLY.

WELLS, DAVID AMES, economist, was born at Springfield, Mass., June 27, 1827. He graduated at Williams College in 1846, and at the Lawrence Scientific School, Cambridge, in 1851, where he was immediately made assistant professor. In 1853 he was engaged with Dr. A. A. Hayes, in Boston, in practical chemistry, and in 1856 he obtained patents for improvements in bleaching. He was afterwards connected with a publishing firm in New York, and edited the *Springfield Republican* for a year. In 1862 he was sent to Europe on a special commission, and from 1866 to 1870 he was a commissioner of the revenue, and produced several very valuable reports. He had now become one of the most pronounced advocates of free trade, and as such received high honor in Europe, being made D. C. L. by the University of Oxford in 1874 and foreign associate of the French Academy of Political Sciences. He has also been prominent in the movement for civil service reform. He assisted in preparing a *History of Williams College* (1847); and edited the *Annual of Scientific Discovery* from 1850 to 1865. He also published *Familiar Science* (1856); *Science of Common Things* (1856), and other popular manuals on natural philosophy, chemistry, and geology; *Practical Economics* (1885); *A Study of Mexico* (1887); and treatises on tariffs and money.

WELLS, HORACE (1815-1848), one of the discoverers of anæsthesia, was born at Hartford, Windsor co., Vt., Jan. 21, 1815. He studied dentistry at Boston and began to practise it at Hartford, Conn., 1836. Moved by the suffering attending some dental operations, he expressed in 1840 the idea that they might be rendered painless by inhaling nitrous oxide gas. In December, 1844, he attended a lecture on "laughing gas," and noticed that a person to whom the gas was administered, meeting with an accident while under its influence, was unconscious of his hurts. Next day he put this discovery to personal proof by having a molar drawn while under the influence of that gas. From that time he used it in his practice and other Hartford dentists followed his example. Early in 1845 he went to Boston, explained his discovery to Dr. J. C. Warren's class and attempted to demonstrate, but unluckily removed the gas too soon and the experiment failed and he, discomfited, was ill for weeks. W. T. G. Morton, formerly his pupil and partner, got the idea from him but was persuaded by Dr. C. T. Jackson to use sulphuric ether instead of nitrous oxide, and applied it in October, 1846, in surgical as well as dental operations. He and Jackson then published and patented their discovery of "letheon" as an anæsthetic and presently quarrelled, each claiming the sole honor from the French Institute. Wells sailed for France in December and his claims were recognized by resolutions of the Medical Society of Paris after three days' discussion. On his return in March, 1847, he put forth a *History of the Discovery*, but the embittered controversy and experiments with chloroform were too much for his bodily and mental health. He went to New York, but became insane and committed suicide Jan. 24, 1848. Hartford erected a statue of Wells in its park and saluted him as the discoverer of anæsthesia, but this honor must be divided. Priestley discovered nitrous oxide gas in 1790, and Sir H. Davy in his *Researches* (1800) proclaimed a belief that it could be

used in surgery. The properties of sulphuric ether were known for the same period and played with by college boys. Dr. Crawford W. Long, of Georgia, used it in his practice in 1842, but never published this application till after it was made and announced by others. Dr. Marcy, of Hartford, a friend of Wells, in January, 1845, performed a successful operation by its aid; but Dr. Morton appears to have been the first to realize its importance for this use, and to seek and gain the credit of its introduction. Flourens, of Paris, showed the anæsthetic effect of chloroform on animals in January, 1847, and in November following, Sir James Y. Simpson, of Edinburgh, introduced it in surgical operations. Of all these contributors to the greatest alleviation yet found for physical suffering, perhaps the most memorable was the unhappy dentist of Hartford.

WESTCOTT, BROOKE FOSS, English clergyman, was born near Birmingham, Jan. 12, 1825. He was educated at Trinity College, Cambridge, graduating in 1848, and being chosen fellow of his college. He was ordained priest in 1851 and became assistant master at Harrow School, holding the position seventeen years. He became canon residentiary of Peterborough in 1869, and regius professor of divinity at Cambridge in 1870. He was also rector of Somersham from 1870 till 1882, and held various positions of honor. In 1884 he was made canon of Westminster. He has given special attention to the history of the English Bible, and from 1870 to 1881 he was a member of the New Testament Revision Company. Among his publications are *History of the Canon of the New Testament* (1855); *Introduction to the Study of the Gospels* (1860); *The Bible in the Church* (1864); *The Gospel of the Resurrection* (1866); *History of the English Bible* (1868); *Revelation of the Risen Lord* (1882); *Revelation of the Father* (1884). He has published commentaries on the Gospel and Epistles of St. John, and has contributed to Smith's *Bible Dictionary* and *Dictionary of Christian Biography*. In company with Dr. Hart he edited the *New Testament in the Original Greek* (2 vols., 1881). Their labors were in great measure the basis of the revision of the English version.

WHEAT. See **AGRICULTURE**, Chap. V. 1.

WHEDON, DANIEL DENISON (1808-1885), theologian, was born at Onondaga, N. Y., March 20, 1808. He graduated at Hamilton College in 1828, studied law at Rochester, and was engaged in teaching. In 1833 he was made professor of ancient languages in Wesleyan University, Middletown, Conn. In 1843 he engaged in pastoral work, but in 1845 he was made professor of rhetoric and history in the University of Michigan. After ten years of service he returned to the pastorate at Jamaica, L. I., but in 1856 he was elected by the M. E. General Conference to be editor of the *Methodist Quarterly Review*. This position he retained by successive re-elections until 1884, when failing strength compelled him to abstain from work. He died at Atlantic Highlands, N. J., June 8, 1885. Besides his editorial work he published many addresses and sermons and contributed to various periodicals. His chief works were *The Freedom of the Will, as the Basis of Human Responsibility* (1864); *Commentary on the New Testament* (5 vols., 1860-75) and *Commentary on the Old Testament* (7 vols., 1880-86), the latter being left incomplete. Dr. Whedon was the ablest exponent of Arminian theology in the United States.

WHEELER, WILLIAM ALMON (1819-1887), nineteenth Vice-President of the United States, was born at Malone, N. Y., June 30, 1819. Early left an orphan, he taught school, spent two years at the University of Vermont, studied and practised law. He became superintendent of schools, district-attorney of Franklin co., and Whig member of the Legislature in 1850. For fourteen years he was cashier of the Malone Bank, and for eleven president of the Ogdensburg

and Rouse's Point Railroad. In 1858-59 he was in the State Senate, and in Congress 1861-63 and 1869-77. His most conspicuous service was in adjusting political complications in Louisiana by the "Wheeler compromise" in 1874. In 1867 he was president of the State constitutional convention, in 1873 a commissioner of the State parks, and in 1876 of the State survey. In the latter year he was a candidate for the Republican nomination for President, but accepted the second place on the ticket with R. B. Hayes, and occupied the Vice-President's chair till 1881. Then he retired to Malone, and died there June 4, 1887.

WHELOCK, ELEAZAR. See **DARTMOUTH COLLEGE**.

WHIG PARTY. This American political organization was the leading rival of the Democratic party (q. v.) during the second quarter of this century. In a measure it was the successor of the old Federalist party, which had been first defeated at the election of Jefferson to the Presidency, and finally destroyed by the victorious close of the war of 1812, which it had opposed. After the war, economic questions came to the front. The war had united the people of the seaboard and of the interior more closely in spirit; but the great natural barriers still obstructed their intercourse. The former Republican party, as directed by Jefferson, wished to refer all questions of internal interest to local legislation, as more directly representing the people affected by them. But the vast extent of roads and canals required to overcome the natural obstacles required larger plans and more liberal aid than the States severally could furnish. Popular leaders who saw the necessity called upon the national government to exert its power for the general welfare. Jefferson himself had waived his theory of government in his purchase of Louisiana; and his successor, Madison, had done the same in chartering the U. S. Bank. National aid to internal improvements had also received favor during the administration of these Presidents. Monroe's administration also wavered in regard to the theory of the strictly limited power of the Federal Government, and in that of John Quincy Adams the liberal view prevailed. This was seen not only in the promotion of internal improvements, but especially in the passage of the protective tariff of 1828. Henry Clay was the leading exponent of this view, but was still classed as a Republican, until the partisans of his jealous rival, Andrew Jackson, succeeded in thrusting him from its councils on account of his aiding the accession of Adams and then entering the cabinet as secretary of state. In succeeding contests, Jackson, who had roused the mass of the people to a sense of their political power, carried with him the great bulk of the Republican party, which now assumed the appropriate title, Democratic.

Clay's adherents, when forming a separate organization, called themselves at first "National Republicans," but soon adopted the briefer title, "Whigs." This name had been used first in Great Britain at the close of the seventeenth century to denote those who favored the authority of Parliament and advocated constitutional limitations of the royal power. Before the American Revolution it had been transferred to this country to indicate in like manner those supporting the rights of the colonies against the encroachments of King and Parliament; and it was, therefore, still highly popular. The Whigs not only favored the tariff of 1828 but also the U. S. Bank and certain internal improvements, which they declared were necessary.

The Whigs held their first national convention in Baltimore in 1831, and nominated Henry Clay for President. But Jackson won the day, with 219 electoral votes against 49 for Clay. In 1832 Clay, in view of the troubles with South Carolina, proposed a compromise granting a reduction of the tariff; but making the change gradual, that the manufacturers might adapt themselves to it. To that end it was pro-

posed to aim at reducing all duties above 20 per cent. ad valorem, to that figure as a uniform rate, but to provide that only one-tenth of the excess should be deducted annually—thus making the last reduction take effect in 1842. Although this measure passed both Houses, yet it was not favored, either by Jackson or Webster.

The steadily increasing pressure of the slavery question tended to divide and demoralize the Whig party. When the House of Representatives in 1838 passed the Twenty-first rule, which declared that every petition, etc., relating to slavery or the abolition thereof should be laid upon the table without being debated, printed, or referred, the Northern Whigs voted against this rule, which became known as the "Atherton Gag;" but the Southern Whigs joined with Northern and Southern Democrats to sustain it. The Whigs were apparently in favor of allowing the Abolitionists the right of petition, yet they were ready to fight them if they used it. They were jealous of the increasing power of the Abolitionists, nearly every vote of whose strength they saw would be taken from their own party. The Whigs were again defeated at the Presidential election of 1836 when William H. Harrison was their candidate. Van Buren had 170 electoral votes, and 114 were distributed among four Whig candidates—Harrison having 73. While the victory of Van Buren was pronounced, he was considered the political legatee of Jackson, and, therefore, all the bitter conflicts of the preceding administration were continued in that of Van Buren. The commercial crisis of 1837, which was undoubtedly due to Jackson's policy, gave an opportunity to the Whigs which was improved to the utmost. The nomination for the Presidency in 1840 should have been given by the Whigs to either Daniel Webster or Henry Clay, had it been decided by the real value of their services, but the working politicians considered that Gen. William H. Harrison was more "available," and he was nominated. The ensuing campaign was probably the most stirring and personal that has ever been waged in the United States. Harrison received 234 electoral votes; and Van Buren, who had been renominated unanimously in his party's convention, had but 60. Tyler, succeeding to the Presidency after Harrison's death, soon proved himself not to be in sympathy with the Whigs, and those of them who had been chosen by Harrison to form his cabinet resigned shortly afterward. Daniel Webster, however, remained secretary of state for some months, in order to complete the negotiations with Great Britain about the boundary line between Maine and Canada.

Meantime the Whigs, under the leadership of Clay in the Senate, succeeded, before a really open rupture with the President came, in repealing the Sub-treasury Act; in enacting a national bankrupt law; distributing prospectively among the States the proceeds of the public lands; and also in enacting the tariff of 1842. The movement to annex the republic of Texas was favored throughout the South, but was opposed by the Whigs in the Northern States. Clay favored the annexation of Texas as soon as that republic ceased its war with Mexico; but the more aggressive policy of the Democrats for such annexation and for the occupation of the Territory of Oregon to the limit of 54° 40' N. gave them a stronger hold upon the popular vote. Clay, in accepting the nomination for President in 1844, expected Van Buren to be his rival, and that the issues would be simply those of internal improvements, the national bank, and a protective tariff. Had the campaign been fought upon these issues it is likely that he would have been elected. As it was, he received only 105 votes as against 170 for Polk, another "available" candidate. To gain support in the South, Clay had written a letter on the annexation of Texas, declaring that he would be glad to see it annexed "without dissension, without war, with the common consent of the nation,

and upon just and fair terms." The effect of this letter was greater in the North than in the South; it carried many Northern Whigs over to the Free Soil party. This defection, more than any other cause, gave the State of New York to Polk by only 5106 votes. The Democrats, being thus thoroughly entrenched in power, repealed the tariff of 1842 and enacted in 1846 a tariff for revenue only. The election of Polk was also interpreted to mean the national approval of the annexation of Texas, and that step involved a war with Mexico. The Northern Whigs then began to recruit the ranks of the Free Soil party. The Whigs of the South, along with Clay, regarded slavery as a legitimate institution not to be hastily interfered with. Both of the parties in the North were also divided upon the question; each had its faction in favor of slavery and another against it. Thus the Mexican war opened with the two political parties divided almost upon Mason and Dixon's line, for the annexation of Texas was an extension of the domain of slavery, and the Mexican war opened up a long vista of such extensions. Then followed a curious phase of political history. Although the war commenced by a Democratic administration was successful from the outset, yet the House of Representatives elected in 1846 had a large Whig majority. The defeat of the Democrats was owing to the tariff of 1846, the failure of the administration to sustain the advanced boundary of Oregon, and, more than all, because the war had been undertaken for the sake of extending the area of the slave States. The Whigs, having control of the popular branch of Congress, attempted to pass the famous Wilmot proviso that slavery should not exist in any territory acquired from Mexico. The administration was strong enough to defeat the proviso; but it was not strong enough to bear down the returning tide of Whig power. The glory which was acquired by Gen. Taylor led to his nomination for President by the Whigs in 1848. Once more Clay and Webster were rejected as the standard-bearers of their party. The managers of the Whigs planned and executed a campaign which avoided the issue upon the slavery question. Their non-committal course alienated some of their party in New England who refused to support Taylor and became known as "conscience Whigs." William H. Seward prevented a similar defection among the Whigs of the State of New York, and Pres. Polk had alienated many Democrats in that State by failing to recognize Van Buren and Silas Wright, whom he distrusted as rivals. The vote of New York went to Taylor and elected him President. His electoral votes were 163, as against 127 for Cass, the Democratic candidate, and none for Van Buren, now the Free Soil candidate. The latter days of that campaign will be ever memorable in the annals of American political history for the combined efforts of William H. Seward, Thurlow Weed, and Horace Greeley to carry the State of New York. Pres. Taylor formed his cabinet in accordance with the non-committal lines upon which the campaign had been fought. The members were drawn in about equal numbers from the North and the South, but the more influential of them were from the North. The re-entry of Calhoun into the Senate and the prodigious efforts of Clay and Webster in that body showed that slavery was still the burning question. It was now 43 years since Clay had first appeared in the Senate, and he was still in full vigor. His resolutions, which were afterward put in the shape of a general measure known as the "Omnibus bill," were to the effect that Congress should not restrict slavery in the Territories; that California should be admitted without restrictions; that Congress had no power to obstruct the slave-trade between the slave States; and that a more effective fugitive slave law should be enacted. The Omnibus bill, though granting largely the demands of the South, was opposed by Pres. Taylor. Had he lived to finish his term it is probable

that the Compromise measures would have been defeated because, as a Southern man, he was enabled to take ground which a President from the North could never have suggested or held. Millard Fillmore, of New York, succeeded to the Presidency, and it was well known that he did not sympathize with Taylor's attitude. He openly used his influence in favor of the Clay Compromise. The Southern Whigs, under the lead of Clay, favored the compromise, but there was earnest opposition from Northern Whigs, who followed William H. Seward. The President approved separately all the bills which had formed the compromise. These were the Fugitive Slave law, the admission of California, the organization of New Mexico and Utah without restrictions as to slavery, and the prohibition of the slave-trade in the District of Columbia. The wedge which had been inserted into the Whig party upon the question of slavery was gradually driven home. In 1852 the Whig Convention met in Baltimore. The Southern members of the party were in favor of Fillmore. Webster was a candidate; but in spite of his famous speech of March 7, 1850, in advocacy of the compromise, he obtained little support among the Southerners. Gen. Winfield Scott was supported by the anti-slavery Whigs, for although he was a Virginian, he had an established military reputation. The votes were strictly upon geographical lines, Fillmore having almost every Southern vote and Scott every Northern vote, except 16 for Fillmore and 29 for Webster. Clay, from his death-bed in Washington, asked his friends to support Fillmore. After a long contest some of the Fillmore delegates went over to Scott and nominated him. The platform, however, was designed to conciliate Southern voters; it accepted the Fugitive Slave law and other kindred enactments as a finality on the questions of the day. In the earlier part of the campaign the Whigs had apparently a very fair show of success; there was much enthusiasm over Scott on account of his war record. But the rival factions of the Democrats in the State of New York came together. Van Buren returned to them and their prospects brightened. The Whigs found that although their platform was acceptable to the Southerners, yet their candidate was not acceptable because of his support by such anti-slavery men at the North as Seward and Greeley. Thus the Whig party lost day by day, and finally Pierce received 254 electoral votes and Scott but 42. This was the last contest in which the Whigs took an active part. All subsequent efforts for the revival of the party were without avail because of the ever-increasing importance of the discussion upon slavery bore down everything before it. The newly-formed Republican party, organized in opposition to the extension of slavery, soon absorbed the anti-slavery Whigs, while the pro-slavery Whigs, after some dallying with the Native American party (*q. v.*) and a futile attempt to organize a Constitutional Union party, found a more congenial home among the Democrats.

Hildreth's *History of the United States* presents a fair view of the Whig party. See also the *Speeches* of Clay and Webster, and Carl Schurz's *Henry Clay* (1887). See in this work REPUBLICAN PARTY.

(F. G. M.)

WHIPPLE, EDWIN PERCY (1819-1886), essayist and critic, was born at Gloucester, Mass., March 8, 1819. Soon taken by his widowed mother to Salem, he attended the public schools. His education, except as it was conducted by himself, ended at 15, when he became a bank clerk; but he had written for the press a year before this. In 1837 he was transferred to a bank in Boston, and thence to the Merchants' Exchange, as secretary and superintendent of the reading-room. This position, while securing him from want, gave him leisure to follow his bent, which was strongly literary, though his training had been much more financial and practical than scholastic. In 1840 he read a poem with eminent success before the Mer-

cantile Association, but all his later work was done in prose. His essay on Macaulay, printed in 1843, won acknowledgment from that author, who became one of Whipple's chief models in style. He soon became a contributor to the *North American Review* and other periodicals, wherein his writings attracted much attention, and were supposed to mark a point midway between the old manner and the new, as typified at the two extremes by Channing and Emerson. Another audience was brought within his reach by the lecture-platform, on which he is said to have appeared a thousand times, though rarely or never going farther than the Middle States. He was never an agitator—a pleader; but many welcomed his frank, dispassionate, and kindly discussion of men and things, and chiefly of ideas and books. His abundant material, always carefully prepared with reference to the requirements of the lyceum or magazine, was but sparingly gathered into volumes. *Essays and Reviews* appeared in 2 vols., 1848, and *Lectures on Subjects Connected with Literature and Life* the next year. A judicious distrust of the patience of audiences appeared in his terse, pithy sentences, neither overloaded with ornament nor burdened with unduly profound thought, but full of sensible observations, fitted to make the every-day reader somewhat wiser. These early books of his were fully up to the requirements of their time, and met unfriendly handling only from Poe, who found the author too genial. Of Poe's acerbity Whipple was incapable; his happy, even, amiable, and manly spirit made no enemies, and had nothing in common with the supposed malignity of critics. He and R. G. White, long the only Americans of established repute in this profession, always wrote of each other in kindly terms; their spheres were so different that they never clashed. In 1850 Whipple was the Boston orator; his subject, suited to July 4th, was *Washington and the Principles of the American Revolution*. In 1860 he resigned his post at the Merchants' Exchange, and gave himself up to a purely literary life, for lecturing with him was merely a convenient method of expression. He was no eager bookmaker, for 17 years elapsed before the appearance of *Character and Characteristic Men* (1866). His lectures at the Lowell Institute, published in 1869 as *Literature of the Age of Elizabeth*, won high praise. *Success and its Conditions* followed in 1871; his *Essays* were collected in six volumes the same year. After his death at Boston, June 6, 1886, two later books were published, with introductions by Whittier and Dr. Bartol, *American Literature and Other Papers and Recollections of Eminent Men*, both in 1887. Whipple was not a man of originality and genius, but he had the respect and fellowship of those who were. He was a figure in the literary life of Boston at its best, and filled a place of his own—the self-taught man who prefers truth by the way of literature to worldly affairs, and reads and thinks that he may write, caring chiefly to sift intellectual and moral values, and get facts and ideas into their true light and relations. The choice was worthy, and nothing in his career belied it. His fame and works are unlikely to live forever, but he was for years a civilizing influence, and to some the best teacher of the matters he took in hand.

(F. M. B.)

WHIPPOORWILL, the common name of the *Antrostomus vociferus*, one of the most common and interesting of the North American birds, of the goat-sucker or night-jar family. To an untrained observer this bird bears a great resemblance to the common night-hawk (*Chordeiles* or *Chordiles popetue*), but its voice and its more strictly nocturnal habits separate the species very clearly; and, on close observation, quite a number of small but important physical marks of distinction are perceptible. Its generic name, *Antrostomus*, or cave-mouth, is an appropriate one; but the latest systematists limit its application by reserving it for the chuck-will's-widow (*A. caroli-*

penis), and by putting its near relative, the whippoorwill, back into the old European genus *Cuprimulgus*, or with the goat-suckers proper. The name "Poorwill" is given to several Western North American species of *Nyctidromus* and *Phalaenoptilus*. The whippoorwill takes its name from its loud and plaintive nocturnal cry. Country people consider it a bird of ill omen, portending death, and especially the death of young children. Its noiseless flight, strictly nocturnal habits, and its loud cry are doubtless the causes of the dread with which the ignorant rustics regard it. The mother-bird lays her eggs generally on a stump or on the bare ground, and makes little or no nest. The bird is not often seen near by. Occasionally the bird may be seen carrying one of its own eggs or one of its unfledged young in its huge mouth. The novelist Cooper calls this bird by the name "Wish-ton-wish," which is not an unapt imitation of its call; but that name properly belongs to the prairie-dog, being its name in the language of the Osage Indians.

(C. W. G.)

WHISTLER, JAMES ABBOTT MCNEILL, artist, was born at Lowell, Mass., in 1834, and educated at West Point. For two years he was a pupil of Charles Gabriel Gleyre in Paris, and in 1863 settled in London. His peculiar and original theories on art have been the subject of much criticism, but he is an artist of strong originality and undoubtedly great talent. In some of his paintings he has succeeded in producing extraordinary and striking effects with but few and quite subdued colors. Among his more important works are *White Girl*, *Gold Girl*, *Blue Girl*, portraits of his mother and Thomas Carlyle, *Princesse des Pays de la Porcelaine*, and *At the Piano*. To many of his later paintings he has given names defining more closely his color-experiments, such as *Nocturnes in Blue and Silver*, *Blue and Gold*, *Blue and Green*, etc.; *Harmonies in Brown and Black*, in *Gray and Green*; *Arrangements in Black*, in *Gray and Green*, in *Gray and Black*, etc. He holds high rank as an etcher, and has executed series of plates on several European cities.

(F. L. W.)

WHITE, ANDREW DICKSON, educator, was born in Cortlandt co., N. Y., Nov. 7, 1832, and in childhood was taken to Syracuse, N. Y. He graduated at Yale College in 1853, having been while an undergraduate an editor of *Yale Literary Magazine*. He then went to Europe and for a time was an attaché of the U. S. Legation at St. Petersburg. He also studied at the University of Berlin and a year after his return to America in 1856 became professor of history and English literature in the University of Michigan. He resigned in 1862 and in 1863 he was elected to the State Senate of New York where he at once took a prominent part in legislation relating to education. He introduced bills codifying the school laws and making a new system of normal schools, and especially aided Ezra Cornell in organizing the Cornell University (*q. v.*). He was then induced to accept the presidency of this institution in 1867, and visited Europe to obtain for it the necessary apparatus. In 1871 he was one of the commissioners sent by Pres. Grant to Santo Domingo and assisted in preparing the report. In the same year he presided over the Republican State Convention of New York. In 1879 he was sent as U. S. minister to Germany, and on his return in 1881 resumed his duties as president of Cornell University. President White has published *Lectures on Mediæval and Modern History* (1861), several pamphlets and lectures relating to Cornell University, including one on the *Co-Education of the Sexes* (1871); *Warfare of Science* (1876); *The New Germany* (1882).

WHITE, RICHARD GRANT (1822-85), critic, philologist, and Shakespearean scholar, was descended from one of the first settlers of Cambridge, Mass., and was born in New York city, May 23, 1822. After graduating at the University of New York, 1839, he studied medicine and law, and was admitted to the bar in 1845, but

did very little practice. Either professionally or personally he was interested in the case of Bishop B. T. Onderdonk, and published an *Appeal from the Sentence* (1845); after the ecclesiastical trial. His newspaper career began the same year as editor of the short-lived *Alleghanian* and contributor to the *Courier and Enquirer*, of which he was associate editor 1851-58. He had been connected with *Yankee Doodle* in 1846, and later wrote for the *World*. His great versatility was early and eminently shown in his writings on music and art—topics which he never entirely abandoned, and on which he was an authority. In 1853 appeared his first volumes, one of them a *Handbook of Christian Art*, and his first magazine article on Beethoven. The civil war turned his literary activity into a new channel; *National Hymns* (1861), was followed anonymously by *The New Gospel of Peace*, in four parts, a pungent and effective satire on Northern sympathizers with the South. A series of letters to the London *Spectator*, from 1863 to 1867, showed no less strong loyal feeling. He edited Burton's *Book Hunter* (1863), the *Record of the New York Exhibition*, and *Poetry of the Civil War* (1866). He was for thirty years a constant contributor to *Putnam's Magazine*, *The Galaxy*, and *The Atlantic*. In the first of these he began to write upon his favorite subject, Shakespeare, or rather the plays, for of their author he professed the lowest opinion ever put forth. *Shakspeare's Scholar* appeared 1853. A variorum edition of the plays in 12 vols. (1857-65) included a memoir and essay separately published in 1865. In the same category belong his *Authorship of the Three Parts of Henry VI.* (1859), and in his last days *Studies of Shakspeare* (1886), previously printed in the *Atlantic* under the more vigorous title of *The Anatomizing of William Shakspeare*. These essays are models of vigor and suggestiveness, though their extreme position repels the sympathy of most readers. White pushes the "no nonsense theory" to all lengths, and berates unmercifully the German and other philosophizers, who insist on judging the man by his writings, and finding a human being with a great soul behind so much immortal poetry. His own view, however it may seem to fit with some of the facts, ignores others, and is less probable as well as less creditable to human nature. According to White, the man and his genius were apart and out of harmony: the man used his genius blindly and basely, caring nothing for what he wrote, reckless of fame and literary values, aiming only to fill his theatre and grow rich. Barely stated, this theory defeats itself and leaves the *Sonnets* unaccounted for; but White urged it with great boldness, tenacity, force, and plausibility, and his essays as well as his editorial labors on the text have an important place in Shakespearean literature. The same dogmatic and pugnacious positiveness, with the same industry, ability, and wide reading, appear in his philological books, *Words and their Uses* (1870; 3d ed., revised, 1880) and *Every Day English* (1879). In a field where every point is hotly and rancorously contested, White is thoroughly at home; had he lived a few centuries earlier he would have been equally zealous as a theologian. In his later years he was much abroad. His *England Without and Within* (1881), like most of his books, was a reprint of magazine articles; E. P. Whipple considered it the best account of the mother country since those of Emerson and Hawthorne. He attempted the international novel with less success in *Adventures of Sir Lyon Bruce in America* (1867) and *The Fate of Mansfield Humphrey* (1884). Mr. White is entitled to a high place in American literature; but his great ability and extensive product have not met adequate popular appreciation, though his record as a magazinist has scarcely been excelled. He had the virtues and some of the vices of a special pleader: he has been accused of hard egotism, narrowness, unfairness to opponents; but he was patient in investigation, honest in his

opinions, and fearless in stating them. His habits were studious and retiring rather than social. With all the enormous literary work that he accomplished, he held the chief clerkship in the revenue bureau of the New York Custom House from 1861 to 1878. He died in New York, April 8, 1885. (F. M. B.)

WHITE, WILLIAM (1748-1836), first bishop of the Protestant Episcopal Church in Pennsylvania, was born in Philadelphia, April 4, 1748 (March 24, O. S.). His father, Col. Thomas White, had emigrated from London 1720, settling in Maryland, whence he removed a year before the birth of his distinguished son. The boy's grave, devout, and blameless character seemed from earliest years to predict his future, and a friend declared that he was "born to be a bishop." From the age of seven he attended the College of Philadelphia, beginning with its English school, and graduated 1765. After a long course of theological study under the local clergy, Drs. Richard Peters and Jacob Duché, he went to England for orders in the fall of 1770 and passed his examination with great credit. He was ordained deacon in December, 1770, and priest in June, 1772. Soon after his return in September, 1772, he became assistant minister of Christ Church and St. Peter's (then and long after united), and married in February, 1773. His calm and gentle wisdom was exhibited on the outbreak of hostilities; he would not preach politics or make the church a recruiting station, but promptly took the oath of allegiance to the United States, retired to Maryland when the British approached the city, and on his appointment as one of the two chaplains of Congress at once proceeded to York and entered on the duties of this office, which he retained as long as Congress met in Philadelphia. On returning thither after the evacuation he was the only Episcopal clergyman in the State; but for his presence and example the prospects of his church would have been much darker even than they were. He became rector of the united parishes in April, 1779, stipulating for his resignation in case of the return of his predecessor, Dr. Duché (q. v.).

After the war had secured the independence of the United States, Dr. White did far more than any other to uplift the church from the confusion, depression, and unpopularity into which she had fallen. Without waiting for peace to be formally declared, he published in August, 1782, a weighty and memorable pamphlet, *The Case of the Episcopal Churches Considered*. Its proposals, that in the councils and government of the church all parishes should be equal and laymen admitted to a share with the clergy, were soon adopted; another suggestion, born of the crying needs of the times, that a superior order of clergy be temporarily provided to take as far as they could the duties of the episcopate till the succession could be procured, was presently invalidated by the conclusion of peace with England, which involved the possibility if not the near prospect of obtaining consecration there. Though few Episcopal ministers remained in America, White did not despair but opened a correspondence with them and with laymen of influence looking to measures of organization. He presided at meetings held in 1784 in his own city and at New Brunswick, N. J., and at the first General Convention in Philadelphia, September, 1785. Here he drafted an address to the English Bishops, which was sent through the U. S. minister, John Adams. At length Parliament authorized these prelates to consecrate Americans: conventions of the diocese of Pennsylvania had met in May, 1785, and June, 1786, and White was elected bishop Sept. 14, 1786. On Nov. 2 he sailed with Dr. S. Provost, who had been likewise chosen in New York. They were consecrated in Lambeth Chapel, Feb. 4, 1787, and landed in New York two months later. Dr. Seabury had been consecrated in Scotland, 1784, as Bishop of Connecticut; he joined his brethren in the convention of 1789 at which the P. E. Church in America was duly organized, Bishop White drawing up its constitution, and with Bishop

Seabury taking the chief part in the revision of the Prayer-Book.

As in forming, so in guiding, Bishop White was the father of his church: his kindly serenity, his wise tolerance, his dislike of extremes, the lofty purity of his character, his lack of narrow and self-seeking views, adapted him to the part alike of leader and peacemaker; his was the directing mind which shaped the church's early course; he was to it "what Washington was to the country," and his writings were its *Federalist*. His *Lectures on the Catechism* appeared in 1813, his *Comparative View of the Controversy between Calvinists and Arminians* in 1817, his *Memoirs of the P. E. Church in the United States*, 1820 (enlarged 1836). The latter has been criticised only as minimizing, if not concealing, his own great services. For forty years he was senior and presiding bishop, active in and beyond his own diocese which under him grew to 86 ministers and 91 congregations. He consecrated 26 bishops. A society which he founded in 1816 was the beginning of Episcopal home missions in the West. A third parish, St. James, was organized in Philadelphia in 1809, and he was rector of the three till his death. With hardly any stipend as bishop, he travelled over the State till 1827, when an assistant was provided. Minutely faithful to every duty, he never left his post, but ministered alike to the sufferers from yellow fever in 1793 and from cholera in 1832. From 1787 he occupied one house in Walnut street above Third. His views were moderately "Low Church," but he was the correspondent of Priestley, the friend of all good men and useful measures. He died July 17, 1836, universally honored and beloved. His *Memoir*, by Dr. Bird Wilson, appeared in 1836; his fittest epitaph is Wordsworth's line, "Sainted White, patriarch of a wide-spreading family." (F. M. B.)

WHITEFISH, the common name of all the species of the genus *Coregonus*, family *Salmonidae*, which are abundant in the Great Lakes and in all the British American Lakes perhaps as far north as the Arctic Ocean. In this section of the Salmon family the body is covered with scales of moderate size, the cleft of the mouth is small, the teeth, if present, are extremely minute and deciduous, the dorsal fin is of moderate length, the caudal deeply forked. The body is elongated but thick, the head small and pointed, the general appearance being like that of the shad. There are in all about two American species, all lacustrine in habitat, each species being localized, though in some cases three or more are found in the same lake. They vary in size from the large lake whitefish, averaging 3 to 5 pounds in weight, to the little "lake herring" of the Saranac Lakes. The whitefish are the most important food-fishes of the Great Lake region, and are of vital importance to some northern tribes of Indians. In quality of flesh they have no superior among our food-fishes, the flesh being white, tender, juicy, and of delicate flavor, and never producing a feeling of satiety like the salmon.

The most important species is *C. clupeiformis*, the large lake whitefish, which is found in all the Great Lakes, attaining its largest size in Lake Superior, where it averages over 5 pounds in weight, though a specimen has been taken of 23 pounds. In the other lakes it is smaller, the usual size brought to market being about 2 pounds. It is in color bluish-gray on the back, lighter on the sides, and white below. This species is supposed to feed on the small crustacea and other small animal forms of the lake waters. It comes in vast shoals into the shallow waters of the lakes to spawn and is then caught in large quantities in nets. Like the shad, it apparently eats nothing during the spawning season.

The species next in importance to the above is *C. artedii*, the "lake herring," of smaller size but one of the most abundant of the great lake fishes. It is a valuable food-fish though considerably inferior in quality to *C. clupeiformis*. In the lakes of the Rocky

Mountain region occurs *C. Williamsoni*, a fish of about a pound weight which ranks high as a food-fish. Another species, *C. Otsego*, known as the "Otsego bass," has as yet been found nowhere but in Otsego Lake. It is about half the weight of the lake whitefish and is said to surpass even this fine fish in excellence. The whitefish were among the first which were subjected to experiments in artificial reproduction. The efforts in this direction were very successful and there is good promise of keeping up a full supply in the lakes by this means.

Many other fish are known as whitefish in certain localities. This title has been given to the bluefish, the menhaden, the tile fish, and the silver salmon, and in Europe is applied to the numerous species of the genus *Leuciscus*, a genus which includes the roach, the chub, the dace, the smelt, the minnow, and other fish of well-known common names. (C. M.)

WHITEHOUSE, FREDERICK COPE, son of Bishop H. J. Whitehouse (1803-1874), of the Episcopal Diocese of Illinois, was graduated with honor from Columbia College in 1861. Possessed of abundant means, he has devoted his life to explorations in many fields of learning and has especially distinguished himself by his examination of Egyptian problems, chief of which is the siting of Lake Moeris. He has by personal and repeated visits and surveys assured himself of the identity of the Fayoum, including the deep depression of Raiyan, with the ancient lake and has suggested to the Egyptian government the expedient of again filling this region with the Nile through the Bahr Yusef and thus greatly enriching the land. His view sustains the truth of Herodotus, and, although many regard it as visionary, it has excited the interest of Egyptologists and the government of Egypt and has many supporters.

WHITE LEAD. In the latter part of the last century the first white lead manufactory was established in the city of Philadelphia, and the success of this establishment soon induced others to engage in the business of corroding lead for the production of the pigment. The growth of this industry was rapid, and early in the present century corroding works were established in the cities of Pittsburg and New York, in the former of which the manufacture of red lead was one of the principal articles produced. The quality of the pigment produced by these pioneers in the business was equal to the imported and the consumption of the home product increased rapidly. The process employed by these corrodors was what is known as the old "Dutch process," and it was not until later years that new processes were employed, but the product of these have never met with popular favor, although the price of what was known as "new process" and "patent process" white lead was lower than the lead made by the older method. At the present time there are thirty-six corroding works in the United States, located in the States of Pennsylvania, New York, Massachusetts, Maryland, Missouri, Kentucky, Ohio, Illinois, California, and Nebraska. Those located in the city of Brooklyn are the largest. Many of these have also added the manufacture of red lead and litharge, while several produce orange mineral superior to the imported.

The products of the corroding works in this country are almost exclusively from the native mineral, and that from the Rocky Mountain district is ordinarily preferred. It is only during seasons of unusual high cost of the native mineral and depressed value of Spanish lead that the crude mineral from the latter country is imported for corroding purposes. The annual consumption of white lead in the United States is about 65,000 tons and is growing rapidly, the average annual increase being about 10 per cent. The capacity of the several corroding works is largely in excess of the production, and for this reason the competition between the corrodors is keen and tends to keep the price of their product so low that the busi-

ness is not at all times profitable. Associations of manufacturers have at different periods been formed for the purpose of regulating the price, but they have been only temporarily successful. A "white lead trust" has recently been formed which embraces a majority of the corroding works in the country. The product of the American works compares favorably with that of the foreign. In former years adulteration was almost universal; later the manufacturers produced several grades with varying proportions of barytes, but now nearly all the corrodors sell the pure pigment only, leaving the adulteration to others. The reliability of the American brands has become so well known that white lead of foreign manufacture is being imported in yearly decreasing quantities. In 1871 the imports of white lead, mostly of English manufacture, reached a total of over 8,300,000 lbs., since which there has been a decline in the imports until for the past few years they have not averaged above 1,000,000 lbs.

The average price of white lead in 1850 was 7 cents per lb. During the late war, in common with all other manufactures, the price advanced rapidly, reaching the highest point in July, 1864, when 21 cents was paid in the New York market. In 1865 the highest price was 18 cents and the lowest price 13 cents per lb. Not until 1870 did the price go below 10 cents, and the average price remained under 10 cents only 3 years. In 1873 the average price was over 10 cents, as also during the succeeding 3 years. In 1879 the average price had dropped to 9½ cents per lb., since which year there have been only moderate fluctuations, with the average price gradually declining until 6 cents was reached, from which the variations have not been important, although the lowest price reached was 5½ cents in 1887.

Most of the red lead now manufactured in this country, owing to the exacting requirements of manufacturers of glass, is made from refined lead, the silver, copper, antimony, bismuth, arsenic, and other foreign metals being removed, so that the oxide produced is in a state of purity not equalled by the older processes. There is also considerable red lead of the very best quality made from the "scraps" produced in the process of corroding white lead. These scraps are the hard lumps of the imperfectly corroded white lead, and are simply oxidized in a reverberatory furnace. As the lead used in the manufacture of white lead must be quite pure, the red lead made from these imperfectly corroded scraps is also very pure and particularly well adapted for glass-making. No estimate of the amount of red lead produced in the United States can be given, as the manufacturers decline to state their output. The imports during the year 1875 exceeded 1,000,000 lbs., but since then there has been a gradual decline, the amount of late years averaging about 250,000 lbs. The price varies with the price of pig lead, while competition has always prevented excessive fluctuations.

The manufacture of litharge in this country has almost entirely excluded that of foreign manufacture, the imports now averaging barely 50,000 lbs. annually, while in 1868 the amount imported was 250,000 lbs. This is due to the quality of the domestic product, it being in every respect equal to the best imported, whereas the latter is of higher cost to the consumer. In the manufacture of glass litharge is not used to the same extent as formerly, red lead taking its place, but for other uses the consumption has increased, and the consumption is of steady growth. The amount produced is not available, as the manufacturers decline to give the desired statistics, although stating "capacity" of their works. The price varies with the cost of pig lead. (H. G. A.)

WHITE PLAINS. See REVOLUTIONARY WAR.

WHITING, WILLIAM (1813-1873), lawyer, was born at Concord, Mass., March 3, 1813. His ancestor came to Boston in 1636, and was the first minister of

Lynn. After graduating at Harvard, 1833, he studied law, was admitted to the bar, 1838, and entered upon successful practice at Boston. His reputation as an authority on the peculiar legal questions arising from the outbreak of the rebellion and civil war attracted the attention of the government and caused his appointment as solicitor of the war department in 1862. Here he wielded great influence in a quiet way on the counsels and activities of Lincoln's administration. His publications were confined to pamphlets, but one of these attracted no little attention at home, and was extensively sold in Europe. *The War Powers of the President, and the Legislative Powers of Congress, in Relation to Treason, Rebellion, and Slavery* (1862) opened and fully occupied a new field. This treatise passed through twenty-seven editions within a few years. In Carpenter's painting of Lincoln and his Cabinet the President directed that this book should have a prominent place. To its original chapters were added in the later editions others on Military Arrests, Military Government, and Reconstruction. Whiting was for some time president of the New England Historical-Genealogical Society, and in his last year was elected to Congress. He died in Boston, June 29, 1873.

WHITMAN, WALT, poet, was born May 31, 1819, at his parents' farm-house, West Hills, western Suffolk co., L. I.; of English stock from the father's side and of Holland Dutch from that of the mother, Louisa Van Velsor. The family moved to Brooklyn early, and in that place and New York city Whitman's boyhood and early manhood passed. He went to the public schools, and in due time learned the printer's trade and worked at it. He also lived in the country on Long Island, taught school, labored at farm toil and house-building, and published a weekly newspaper. New York and Brooklyn, however, were his principal head-quarters till he was nearly 30 years of age, when he started travelling, first to Louisiana, passing a year there, and then to leisurely visits and occupation, in nearly all the Southern and Western States, one after the other. Then, returning to Brooklyn, he put in shape and issued (1855) the first portion of *Leaves of Grass*, which has been fashioned and increased until now (1889) it is considered finished by the author's last pieces, *Sands at Seventy*, as annex to the previous ones.

During 1862 to 1865, inclusive, Whitman was arduously occupied in the area of the civil war in Maryland and Virginia and in and around Washington City, with the wounded and sick of the armies, both Northern and Southern, giving fully three years to those special ministrings. He had always possessed the best health and strength, but about the close of the contest he was prostrated by a severe stroke of paralysis. Though he surmounted it, a broken physique resulted, and some six attacks have at times followed from it since.

His literary works are comprehended under three titles, the *Leaves of Grass*, his main work and form of poetic expression, passing through five stages or increments, beginning in 1855 and completed in 1888; his prose book, *Specimen Days and Collect* (1883), forming biographical notes, personal memoranda during the civil war, with various essays, including "Democratic Vistas." He has never recovered from the physical paralysis of the war period and agitation of 1860 to 1865; but, his mental powers remaining unaffected, he has worked steadily at his literary plans, and during 1888, in his seventieth year, finished the booklet of *November Boughs*, his last work, containing both poems and prose.

The time has probably not yet come for pronouncing definitely on Walt Whitman's place in literature. His main characteristics may safely be said to be daring originality in thought as well as in form, contempt for conventionalities, marvellous fecundity and felicity of expression, and boundless admiration for democracy as developed in the America of to-day, or

rather, it may be, in that ideal America that looms up before his poetic eye. By not a few he is held to stand side by side with Emerson as one of America's truly representative geniuses. Others, startled by the outré appearance of his rhymeless verses, his defiance of conventionalities and his frequent mysticism, see little to admire in him. He is highly appreciated in England, and his pieces have been translated into several modern languages.

His tender care for the wounded and sick during our civil war have endeared him personally to every true American. Nothing can be more touchingly eloquent than some of his letters to his mother descriptive of the scenes he witnessed in the hospitals. He resides on Mickle street, Camden, in a plain frame dwelling which has become a shrine where he receives the homage of numerous devoted admirers, not a few from foreign lands. He is a bachelor, and his real amiability and charm of character endear him to all who know him.

WHITNEY, ELI (1765-1825), the inventor of the cotton-gin, was a farmer's son, born at Westborough, Worcester co., Mass., Dec. 8, 1765. His early advantages were limited, but his mechanical gifts were shown and utilized in childhood. At 16 he began to manufacture nails, and followed with pins and canes. Entering Yale College at 24, he worked his way through the course, and after graduating, in 1792, accepted a private tutorship in Georgia, but on arriving found the place given to another. The widow of Gen. Greene took pity on his necessitous condition, entertained him at her house near Savannah, and, finding him useful in making or mending any sort of implement, referred to him some neighbors who were troubled by the slow and laborious process of separating cotton from its seed. Whitney had then no acquaintance with the plant, but found specimens of its seed and went to work. Full of inward resources, though sadly lacking in external facilities, he made his own tools and wire, and had success in view when the eager impatience and selfish greed of unknown persons delayed the execution of his plans and opened the way to innumerable vexations and disappointments. His first machine, kept secret and under lock, was stolen when yet incomplete, copied, and put in operation before he was able to produce another and secure a patent. He would now have been helpless, but that Miller, tutor to Mrs. Greene's children and afterward her husband, entered into partnership with Whitney in May, 1793, and supplied funds till his death in 1803. Whitney went North to construct the gins and obtained a patent March 14, 1794, which was contested in Georgia. His history embraces all the proverbial trials of inventors, which he met with indomitable patience, resolution, and tenacity. One difficulty after another arose in his path. He could not manufacture enough machines to supply the demand of an increased crop of cotton, planted in reliance on the invention, and the stolen gins, however inferior to his, were eagerly purchased. Obligated to borrow money at high rates, the burning of his shop with all its contents made him a bankrupt. The gins were brought into discredit for a time by an unfounded idea in England that they weakened the cotton in cleaning it. When this prejudice subsided, the market was stocked with pirated machines, which became yet more abundant when the first suit brought for violation of patent was decided against the inventor. Worn out with the injustice of Georgia, he sought relief in other States. The Legislature of South Carolina in 1801 voted him \$50,000 for the State right to his gin, but many delays, annoyances, insults, and expenses ensued before the sum was paid. In Tennessee he received fair promises, which were soon disowned. In North Carolina alone was he fairly treated; a tax imposed in 1802 for five years on every saw employed in ginning supplied him with means to prosecute his suits in Georgia. There in 1807 he obtained a tardy injunction on infringe-

ments of his patent. Under the urgency of the Southern members, Congress in 1812 declined to renew this patent; though its inventor had doubled the wealth of the cotton States by developing their chief industry, he was not entitled to a continued reward. His chief means were drawn, not from the cotton-gin, but from the manufacture of implements of destruction. Seeing the need of another resource, he had begun to make arms in 1798, and obtained a large contract from Oliver Wolcott, secretary of the treasury. Obligated to do everything from the first steps on, he was unable to furnish 10,000 muskets in 2 years, as he had agreed; but the time was extended to 10 years and the funds advanced as he needed them. The treatment he received from government in this case was in happy contrast to the ingratitude and injustice which repaid his far more useful and important services. By degrees he built up a great arsenal at Whitneyville, Conn., filled large orders for the United States and New York, introduced improvements in firearms and other iron commodities, and realized a fortune. Yet it was the cotton-gin alone which, in Fulton's opinion, placed him with Watt and Arkwright among the greatest recent benefactors of mankind. He married a descendant of Jonathan Edwards in 1817, and his later years were passed in peace and comfort. He died at New Haven, June 8, 1825. (F. M. B.)

WHITNEY, JOSIAH DWIGHT, geologist, was born at Northampton, Mass., Nov. 23, 1819. He graduated at Yale College in 1839, and spent five years in scientific studies in Europe. He has been engaged on the geological surveys of Ohio, Mississippi, Michigan, and California, beside the U. S. government surveys of the Territories. In 1865 he was made professor of geology in Harvard University. He is a member of the American Association for the Advancement of Science and of other scientific bodies. His publications include *The Metallic Wealth of the United States* (1854), and *Reports on the Lake Superior region*, the upper Mississippi lead region, and the *Geological Survey of California* (1864-70). He contributed to the *ENCYCLOPEDIA BRITANNICA* that part of the article UNITED STATES which relates to physical geography.

His brother, WILLIAM DWIGHT WHITNEY, philologist, was born at Northampton, Mass., Feb. 9, 1827, and graduated at Williams College in 1845. After three years spent as a bank-clerk, he began the study of Sanskrit at New Haven, 1850, and went abroad the next year to pursue it more fully. For three years he labored at Berlin and Tübingen, and planned with Prof. Roth an edition of the *Atharva-Veda-Samhitā*, which appeared in 1856. For this he made copies and collations of all the MSS. in Europe. In 1854 he was appointed to the chair of Sanskrit in Yale College, founded for him by Prof. E. E. Salisbury (q. v.); to this was added comparative philology in 1870. Besides these he has long held an instructorship in modern languages. He joined the American Oriental Society 1849, was its librarian 1855-73, and its corresponding secretary from 1857, spending much time in its service, and contributing largely to its *Journal*, of which he was long the chief editor; the greater part of vols. v.-ix. is from his pen. His edition of the translation by E. Burgess and others of the *Sūrya-Siddhānta*, or text-book of Hindu astronomy, appeared at New Haven 1860. Two years later he published the *Atharva-Veda-Prātiśākhya*, text, translation, and notes, and in 1871 another Hindu grammatical book, *Taittirīya-Prātiśākhya*, which received a prize from the Royal Academy of Berlin. His lectures on *Language and the Study of Language*, delivered at the Smithsonian Institution 1864, and later at the Lowell Institute in Boston, appeared in 1867, and a German translation by Dr. J. Jolly, 1874. His labors have not been confined to Sanskrit; his *German Grammar* (1869) and *German Reader* (1873) have been much praised and used, and he has prepared similar works in French and English. His

Oriental and Linguistic Studies appeared 1872, and a second series 1874. His *Life and Growth of Languages* (1875) formed part of the "International Scientific Series," and was translated into French and German 1876. His *Sanskrit Grammar* was published at Leipsic, 1879. He aided in the preparation of the *Sanskrit Lexicon* at St. Petersburg (1872-5), and has written for several German publications, and at home for Appleton's *Cyclopædia*, the *Bibliotheca Sacra*, the *New Englander*, etc. He was the first president of the American Philological Association. He is chief editor of the *Century Dictionary of the English Language* (1889). He has a European no less than a national fame, and is considered by many the foremost expositor of the science of language.

WHITTIER, JOHN GREENLEAF, one of the most popular and representative of American poets, was born at Haverhill, Mass., Dec. 17, 1807, in the farmhouse built by his ancestor, Thomas Whittier (1620-96), who came from Southampton, England, to Boston in 1638, and settled at Salisbury on the Merrimac and 10 years later at Haverhill. The family, for a generation or more before the poet's time, were Quakers, and to that connection he has adhered. On his mother's side he had in Stephen Bachiler, first minister of Hampton, N. H., a common ancestor with Daniel Webster. His early life on the farm, and the various members of the family, are described in his poem *Snow-Bound*, and other of his writings record his childish experiences. He was fond of reading, and began to rhyme at fourteen, stimulated by the loan of a volume of Burns. His first printed verses appeared in a local paper in 1826, and W. L. Garrison, then editing the *Newburyport Free Press*, called at the farm-house, encouraged and praised the young poet, and urged him to seek further educational advantages than the district school had afforded. By making shoes during the winter he earned enough to cover his expenses for six months at the Haverhill Academy, which he entered in April, 1827. In the winter following he taught school at West Amesbury, now Merrimac. He began to write verses for the *Haverhill Gazette* 1828, and continued these contributions for nearly forty years. In the fall of 1828 Garrison, then in Boston, found him a place as writer on the *American Manufacturer*. This sheet he practically edited for some months, receiving \$9 a week, and meanwhile he wrote some verse for John Neal's *Yankee*. From June, 1829, to July, 1830, he was at home, working on the farm, the latter months editing the *Gazette*, and writing for the Hartford *New England Weekly Review*. He assumed the editorial chair of this paper in July, 1830, succeeding G. D. Prentice, and retained it eighteen months; during that time, besides many prose sketches and tales from his pen, it contained 42 poems of his, among them *The Vaudois Teacher*, which in a French version was greatly valued in the lower Alps, long before its authorship was known. His first volume, *New England Legends in Prose and Verse*, appeared at Hartford in February, 1831. Most of these early efforts were lightly regarded and suppressed by their author in after years, but they gave him a certain reputation at the time. Before leaving Hartford he edited Brainard's *Poems*, and prefixed a sketch of that writer's life; the book was published early in 1832. That year Mr. Whittier was at home writing for Buckingham's *New England Magazine*, in which appeared *Mogg Megone* (in a volume, 1836). *Moll Pitcher* was published at Boston 1832. Garrison's *Liberator*, begun 1831, much influenced Whittier, who printed at his own expense a well-reasoned pamphlet of 23 pages, *Justice and Expediency, or Slavery Considered with a View to its Rightful and Effectual Remedy, Abolition* (Haverhill, 1833). Of this Arthur Tappan (q. v.), of New York, soon had 10,000 copies struck off for gratuitous distribution. This was the beginning of the poet's long and active share in the anti-slavery agitation. He handled the same topic in

five pages of the *Providence Journal*, July, 1833, and again in the *Essex Transcript*. He was a delegate to the National Anti-slavery Convention at Philadelphia, Dec. 4-6, 1833, and as one of the secretaries signed its *Declaration of Sentiments*. An anti-slavery society was formed at Haverhill, April 3, 1834, of which he was an officer and doubtless a leading spirit. The unpopularity of the cause did not prevent his being sent to the Legislature in 1835. The same year he had several experiences with mobs. He concealed George Thompson for two weeks, and soon after, with that English leader, narrowly escaped ill treatment at Concord. Meantime he continued to write prose and verse, largely on this subject. His spirited attacks on the clergy of Southern opinions and sympathies, as a *Pastoral Letter* (in the *Liberator*, October, 1837), called forth by a Congregational council at Brookfield, which tried to silence the Grimké sisters, *Clerical Oppressors*, etc., won the honor of liberal denunciation. His *Poems chiefly relating to Slavery* were published by Isaac Knapp, of the *Liberator*, Boston, 1838. The poets were generally for freedom, but S. J. May with abundant truth called Whittier "our laureate," and testified that "from 1832 to 1865 his harp of liberty was never hung up." The effect of these fiery strains in moulding the slow-growing popular sentiment which at last swept the land was inestimable. From his father's death in 1832 to 1837 the poet managed the farm, just making ends meet for the family. From May to December, 1836, he again edited the *Haverhill Gazette*. In the summer of 1837 he spent three months in New York as a secretary of the National Anti-slavery Society. At the end of that year he went to Philadelphia to write for the *Pennsylvania Freeman*, and was its editor from March 15, 1838, to Feb. 20, 1840. Nearly a third of this time he was at home in Massachusetts, or travelling for the society in Western Pennsylvania. His *Ballads* (180 pp.) were published in Philadelphia by the society, November, 1838. In May, 1838, the office of his paper was in the new Pennsylvania Hall, which was promptly sacked and burned by a mob. In May, 1840, he left Philadelphia for Amesbury, Mass., whither his family had removed (partly to be nearer their meeting-house) after selling the farm. Here he lived by his pen, and continued his anti-slavery labors, travelling much with H. B. Stanton in the interest of the cause; Wendell Phillips called him "a superb hand" at lobbying. *Lays of my Home*, etc., appeared in 1843. In 1844 he spent six months at Lowell, Mass., writing for the *Middlesex Standard*; some of these articles were reprinted in Boston as *The Stranger in Lowell* (1845). The Mexican war called out his active opposition. *Voices of Freedom* appeared at Philadelphia in 1849, and added much to his reputation. From 1837 to 1846 he wrote much for the *Democratic Review*; in this some of his best poems appeared, as *The Bridal of Pennacook* (1844-5). *The Supernaturalism of New England* was published in New York and London in 1847. The *National Era* was established at Washington in January, 1847, and Whittier was its assistant and corresponding editor till September, 1859. During these years he contributed to its columns more than eighty poems and a great quantity of prose, including *Old Portraits and Modern Sketches* (collected, 1850), *Literary Recreations* (1854), and *Margaret Smith's Journal*, 1678-99, a historical novel reprinted in Boston in 1849, and called by Miss Mitford a clever mystification. An illustrated collection of his poems in octavo was brought out 1849 by B. B. Mussey & Co.; the plates were afterward bought by his later publishers, Ticknor and Fields. *Songs of Labor* (1850) were gathered from the *Review* and *Era*. A selection from his poems was published in London, 1852, by Routledge. *The Chapel of the Hermits* and *A Solitary Scene* appeared in 1853. *The Panorama*, etc., 1856, and a complete edition of his poems to date, 1857. Of his more notable short

pieces, *Ichabod* (on Webster) was first printed in the *Era*, May 2, 1850, to C. S. (Sumner) and *Maud Muller* in December, 1854. But many of his lyrics cannot be traced thus. He bore a part in founding the *Atlantic Monthly*, and was one of its writers from the start. Of his *Home Ballads*, etc. (1860), the *London Athenæum* said, "Here is poetry worth waiting for, and a poet worth listening to." In *War Time*, etc. (1863), contained some of his most fiery deliverances. *National Lyrics* (1865) was a small volume of selections. His *Prose Works* were collected in two volumes in 1866. With the abolition of slavery and the restoration of the Union, the great cause he had championed so earnestly was won, and the fighter could lay aside his weapons and turn gladly to congenial themes of peace. After the tremendous war-song, "We wait beneath the furnace blast," came the triumphant *Lauds Deo*. His muse, always pious, now became eminently sweet and saintly. *My Psalm* (1859) was a forerunner of *The Eternal Goodness* and *Our Master* (1867). From the last several hymns have been extracted, to be used and greatly valued both in England and in America; nowhere has the inmost spirit of Christianity been more exquisitely portrayed. *Snow-Bound* appeared 1866. *The Tent on the Beach*, etc. (1867), records a camping experience with Bayard Taylor and J. T. Fields. Several of the lyrics are among his strongest and loveliest. It was followed by *Among the Hills*, etc. (1868). *Miriam*, etc. (1870), *The Pennsylvania Pilgrim*, etc. (1872), *Mabel Martin* (1874), and *Hazel Blossoms* (1875); the last includes a few poems by his sister, Elizabeth Hussey Whittier (1816-64). On the poet's seventieth birthday, Dec. 17, 1877, the publishers of the *Atlantic* gave a memorable dinner in his honor: the *Literary World* issued a special Whittier number, with tributes in verse and prose from many eminent writers. Before this a college at Salem, Iowa, had been named from him. His later books are *The Vision of Echard*, etc. (1878), *The King's Missive*, etc. (1881), *The Bay of Seven Islands* (1885), and *St. Gregory's Guest*, etc. (1886). A complete edition of his *Works*, including both poetry and prose, has been supervised by himself (7 vols., 1888-89).

The poet and the man are not easily separable in Whittier. Vice-President Wilson said on his death-bed, "I believe him the purest man living on earth." Channing saw in him "noble simplicity of character, and the fire and energy of an ancient prophet." Whipple bore witness in 1844 to his "vehement sensibility, the stormy qualities of his mind," and "the soul of a great poet." H. T. Tuckerman in 1852 saw in him "the imaginative fervor of a devotee, both of nature and of humanity," as well as "a prophetic anathema and a bardlike invocation." Vapereau (1858) called him "full of clan and vigor." These great qualities have their defects. His task is not always perfect; his "fiery protesting spirit" is sometimes indifferent to literary detail and finish. Lowell wrote in 1864, "If the most fervid of our poets, he is sometimes hurried away by this very quality into being the most careless." His rhymes are often faulty beyond the most provincial license of Burns. That was in his polemic time, when his loveliest lyrics were not yet written. So *Fraser's Magazine* in 1859 pointed out "his faults, harshness, and want of polish," but recognized "more life and spirit and soul in his verses" than is apt to be found in those of more patient and elaborate workmen. Mr. Whittier, in a green old age spent between Amesbury and Danvers, Mass., enjoys the fruit of his faithful planting, in "love, honor, troops of friends." His life has already been written by W. S. Kennedy (1882) and by F. H. Underwood (1884). (F. M. B.)

WILDERNESS CAMPAIGN, THE. This title is intended to include the series of engagements in the American civil war fought during Grant's overland march to Richmond, embracing the battles of the

Wilderness. Spottsylvania Court-House, down to COLD HARBOR, already described in this work. It comprises a succession of great conflicts and skilful marches, occupying a single month of time (from May 3 to June 3, 1864), which radically changed the aspect of the war and placed the army of the North in position to successfully terminate the long-continued struggle. The whole campaign demands to be dealt with as but a single event of the war, its several incidents being parts of one great whole.

From the battle of Gettysburg, in July, 1863, to the beginning of May, 1864, no important military events had taken place in Virginia, the operations of the armies being confined to inconsequent marches in unsuccessful efforts to obtain advantages of position. On March 9, 1864, Gen. Ulysses S. Grant was made commander-in-chief of all the United States armies with the rank of lieutenant-general. He at once placed Sherman in command of the Western armies and took the field in person with the Army of the Potomac, though Meade still retained its immediate command. Grant's plan embraced a movement in concert of all the armies of the Union. The Army of the Potomac at that time lay just north of the Rapidan, a branch of the Rappahannock River, facing the Confederate Army of Northern Virginia, under Gen. Robert E. Lee, which lay south of the Rapidan with a strongly-intrenched position at Mine Run. The force under Gen. Grant is stated by himself to have been about 116,000 men; that under Lee is claimed by Confederate historians to have been only 64,000 men, but is estimated by Grant at 80,000. Such discrepancy in numbers as existed was negated in the succeeding engagements by the reversed relations of the two armies, Grant constantly fighting on the offensive, Lee usually on the defensive and behind intrenchments.

Shortly after midnight, on the morning of May 4, 1864, the movement of Grant's army toward the Rapidan began. At the same time Butler with 20,000 men moved from Fortress Monroe up the south side of the James River, and two days afterwards Sherman advanced from Chattanooga on his march towards Atlanta. The grand movement of all the armies had simultaneously begun. On the morning of the 4th the right wing crossed the Rapidan, followed during the day by the remainder of the army. Grant states in his *Memoirs* that he expected severe opposition in crossing the river, and considered that he had gained a great advantage in being suffered to cross unopposed. He believed that his success was due to Lee being taken by surprise by the suddenness of the advance movement.

The army now pushed immediately into that difficult country known as The Wilderness, in whose wilds Hooker had received so severe a repulse just a year before at Chancellorsville (*q. v.*). The region thus named was an exceedingly difficult one for military operations, being covered by a dense thicket of second growth, replacing the primeval forest which had been cut to supply fuel to neighboring smelting furnaces. This thicket extended for miles but was intersected by several roads, by which alone could troops be moved. The right column pushed directly into the Wilderness, the left to Chancellorsville, where it bivouacked for the night. Grant hoped that another day's march would take him through this region and that by a rapid advance on Gordonsville he might place himself in the rear of Lee's army. In consequence, early on the morning of the 5th, the whole army was put in motion for this purpose.

Lee, meanwhile, was well aware of the advantages of the Wilderness as a battle-ground, its intricacies being familiar to him and his generals while unknown to his opponents. He had already gained a victory over a superior force there and hoped to do so again. He therefore resolved to give Grant battle in those wilds. The thicket was traversed by a turnpike and a

plank road which ran eastwardly, nearly parallel to each other, from Lee's head-quarters near Orange Court-House. Along these roads Lee's army advanced on the morning of the 5th, Ewell's columns following the turnpike, the more northerly road, and Hill's the plank road. Longstreet's division, which had been stationed at Gordonsville, 20 miles off, did not arrive in time to take part in the battle of that day. This was the case also with Burnside's division of Grant's army, which had been lying on the Rappahannock.

Grant's army had not advanced far before the heads of the enemy's columns were felt. It was at first supposed that this was but a strong rear-guard to cover Lee's retreat, and dispositions were made to sweep it away and seize the intrenchments on Mine Run, the day being well advanced before it was clearly perceived that Lee's army was there with the intention of fighting. The affray opened with a struggle of skirmishers and of small parties of cavalry and infantry sent to their support, but action in force did not begin till about noon, when Ayres's and Bartlett's brigades of Griffin's division were sent through the thicket to the right and left of the turnpike to disperse the force in front. The Confederates were driven in, not being prepared for this onset, and a larger force might have crushed Ewell's corps had the true state of the case been known to the Union commanders. But the danger to the Confederates was averted by the quick advance of Stewart's brigade and the timely arrival of Rodes's division, these new troops at once attacking vigorously. Orders had been issued to support Warren's advanced brigades by the left of Sedgwick's corps, but the passage through the thicket proved so difficult that Ayres and Bartlett were hurled back before support could reach them. The fighting was desperate and ended in a decided advantage to the Confederates, who captured two guns and a number of prisoners and won the contested ground. Gen. Wadsworth, who had advanced to co-operate with Griffin, went somewhat astray in the woods and was met by a flank fire which drove him back in some confusion. On the left of Wadsworth the brigade of McCandless found itself isolated and nearly surrounded, and lost two full regiments in the effort to escape from its dangerous position. The result of the engagement was a loss of about 3000 men to Warren's corps and the possession of the contested ground by the enemy, Warren retiring to form a new line a little in the rear. Shortly after 1 P. M. the head of the Sixth corps, which was advancing to support the Fifth, was attacked by Ewell. In the conflict that ensued the Confederates were at first repulsed, then the Sixth was driven back by a furious charge of Rodes's division, and finally the Confederates were again driven, the Union forces holding the ground. This ended the fight for the day in that quarter.

Two hours before Griffin's advance Grant had fathomed Lee's intention to give battle in the Wilderness and made the necessary preparations. To Hancock, who was advancing with the Second corps, he sent word to march with all haste by the Brock Road which crosses the plank road nearly at right angles, while Gen. Getty, of the Sixth corps, was ordered to hold the junction of these roads with his division until joined by Hancock. He did so, though pressed severely by Hill, who was seeking to gain possession of the same strategic point. Hancock's advance reached Getty's position about 3 P. M., and soon the whole Second corps was there and the junction secured. Shortly afterward Hancock, who had begun to throw up breastworks, was ordered to advance on Hill and drive him back. A sanguinary battle ensued at close quarters, but Hill maintained his ground firmly until after nightfall, when the fighting ceased, the combatants resting for the night so near each other that both drew water from the same brook. Thus ended the first day's battle in the Wilderness.

The battle was resumed early in the morning of the

6th. During the night Longstreet had bivouacked near the intrenchments on Mine Run, and was ordered to take position on Hill's right; while Burnside arrived before daybreak and marched to occupy the position between Warren and Hancock. Grant's line of battle, now fully formed, extended from Todd's Tavern on the Brock road to near Germanna Ford, crossing the turnpike and plank road nearly at right angles and presenting a front of about five miles. Sedgwick occupied the right; Warren joined him on the left, his line crossing the turnpike; Burnside took position on Warren's left, and Hancock lay on the extreme left, occupying the Brock road and its junction with the plank road. Lee's army remained as on the day before, Ewell on the turnpike, facing Sedgwick and Warren; Hill on the right, across the plank road; while Longstreet was advancing towards his position on Hill's right, facing Hancock.

So stood the opposing armies on the morning of May 6, ready to engage in one of the most singular and desperate conflicts the world had ever known. Swinton well states the case: "Manœuvring here was necessarily out of the question, and only Indian tactics told. The troops could only receive direction by a point of the compass, for not only were the lines of battle entirely hidden from the sight of the commander, but no officer could see ten files on each side of him. Artillery was wholly ruled out of use; the massive concentration of 300 guns stood silent, and only an occasional piece or section could be brought into play in the roadsides. Cavalry was still more useless. But in that horrid thicket there lurked 200,000 men, and through it lurid fires played, and, though no array of battle could be seen, there came out of its depths the roll and crackle of musketry like the noisy boiling of some hell-caldron that told the dread story of death."

Grant recognized the difficulty of the situation and gave but a single general order: "Attack along the whole line at five o'clock." Lee, however, began the battle, by an assault a little before this hour, with the purpose, as is asserted, of occupying the Union lines till Longstreet could get into position, when he hoped by a sudden and vigorous attack on Hancock's flank to drive his antagonist back to the Rapidan. If such was his design it was defeated, Longstreet not reaching his position as early as hoped for. The battle began in a fierce musketry assault on the extreme right of Sedgwick's corps and a desperate effort to break through his lines. This was easily repelled, and Sedgwick made a partial advance, while at the same time Warren and Hancock attacked the foe in their front. Hancock's movement was at first successful. The Confederates were forced out of their rifle-pits, many prisoners with five battle-flags were captured, and Hill's troops driven back in confusion. At this critical juncture Anderson's division of Hill's corps came up and checked the retreat, and the head of Longstreet's column, which had been marching to flank Hancock, made its appearance in front.

It was now 9 A. M. Hancock reformed his lines, which had received reinforcements from Burnside, and resumed his advance, but found himself speedily checked by a large force. Longstreet had been recalled from his flanking march and ordered to Hill's assistance, and Hancock had the greater portion of the Confederate army before him. The battle that ensued was fierce and sanguinary, Hancock making vigorous efforts to break the strong lines in his front, and losing heavily in the effort. About 11 A. M. a fierce assault was made on his left, by a strong force which Lee had sent to carry out his original plan of flanking the Union line with the hope of doubling it up, and driving the whole army back to the Rapidan. Hancock was forced to fall back before this overwhelming charge, Gen. Wadsworth falling with a bullet through his brain as his line was forced to retreat.

At this point in the contest a serious misfortune befell the Confederate cause. Longstreet was pressing

forward with the vigor which he had shown since his first arrival on the field, pushing back Hancock in front and endeavoring to seize the Brock road on his flank, where he himself fell by a bullet from one of his own men. He was riding, with his staff, in front of his column, when he came upon the van of his flanking force. His men, mistaking the group of officers for Union cavalry, fired, and Longstreet fell with a severe wound, which disabled him for months. This accident seriously deranged the Confederate plans. The lines were thrown into confusion and the advance ceased, while Lee, as soon as he heard of the misfortune, hurried to the spot to take charge in person of the important movement he had ordered. This check was of vital importance to Hancock. While Lee was rallying and reforming the troops and preparing for a fresh advance, a labor which consumed four hours, Hancock had reoccupied his intrenchments on the Brock road and made preparations for the threatened attack.

At 4 P. M. the columns of Longstreet and Hill, led by Lee in person, advanced in serried masses upon Hancock's position, and vigorously assailed the line, which lay behind a strongly built breastwork of logs. The contest soon became hot and furious. The incessant volleys of musketry set fire to the woods, which quickly became filled with flame and smoke. Soon the Union breastworks were on fire, and ere long the whole line of logs was a mass of seething flames, the smoke and ashes being driven by the wind in the face of the Union troops. The battle went on through smoke and flame, a portion of the breastworks not yet on fire being taken by a fierce Confederate charge. The moment was a critical one, but Col. J. W. Hoffman rushed forward with a small body of men, drove the assailants out, and retook the works. This, as Hancock declared, saved the day on the left. The intrenchments had proved too strong to carry, and no further effort was made.

On the right the fighting was less severe. Sedgwick had made a strong effort to carry Ewell's intrenched lines, and had lost heavily in doing so. Warren had remained mostly on the defensive. As night approached it was supposed the battle was at an end, but Lee had another surprise in store. Just at sunset a heavy column, led by Gen. Gordon, advanced from Ewell's extreme left, and fell heavily and unexpectedly on Sedgwick's wearied troops, who were utterly unprepared for such an assault. It was a moment of peril. The right wing of the army seemed in imminent danger. The charging column fell first on the brigades of Seymour and Shaler, of Rickett's division, drove them back confusedly, and captured several hundred prisoners, including both commanders. But Sedgwick swiftly hurried men to the defence, the Confederate advance was checked, and the darkness of night soon put an end to the violently contested battle. During the day the cavalry had taken no part, except a brief contest between Sheridan and Stuart in the open country far to the left of Hancock's lines.

The losses were severe. Careful estimates place the Union loss during the two days' battle at nearly 18,000 men, of whom 6000 were made prisoners. The Confederate loss was probably about 11,000. Fierce as the battle had been no advantage in position was gained by either party. The Union army rested during the night on precisely the grounds it had occupied in the morning. With the dawn of the 7th the men rose ready to renew the battle, if necessary. But Lee had evidently had enough of offensive fighting, great as was the advantage to him of his knowledge of the ground. The skirmish line sent out at daybreak found the Confederates behind intrenchments, to attack which, in that impracticable wilderness, would have been a desperate and dangerous attempt for the Union army. Grant at once decided not to do so, but to get out of the wilderness and into more open country without delay. Thus ended the first act of the Wilderness campaign.

At 9 P. M. on the 7th Warren moved from his lines

and began a march along the Brook road, towards Spottsylvania Court-House, 13 miles distant. Hancock was to follow him, and Sedgwick and Burnside to march by way of Chancellorsville. The hope was entertained that the point in question could be reached before Lee became aware of the movement. Warren, however, met with obstructions, first from Union cavalry which occupied the road, and afterward from barricades of heavy trees which had been felled across it. Hours were lost in consequence, and it was 8 A. M. before the head of the column reached a point 2 or 3 miles from the Court-House. No opposition had been met except from dismounted cavalry, but at this point an unexpected and severe check was received, in a murderous fire of musketry which hurled the leading brigades backward, until met by Warren, who rallied and reformed them. Griffin's division was similarly received, and Warren's corps, as its divisions successively came up, formed into line of battle, and at once began to intrench.

This check was due to the head of Longstreet's column, then commanded by Gen. Anderson, which was already on the ground. The attempt to surprise Lee by a flank movement had, in fact, failed. He had been apprised by Gen. Stuart that the Federal wagon trains were moving southward. At once conceiving of Grant's design, though ignorant of the threatened point, he ordered Anderson to move from the breastworks, and encamp at a point where he would be in position for a march on Spottsylvania in the morning. The burning woods, however, rendered bivouacking impracticable, and Anderson marched on through the night, so that it was rather by accident than design that he reached Spottsylvania in the early morning, in time to throw the head of his column across Warren's line of march. Mingled accident and design had foiled the attempt to flank Lee's army.

The remainder of the day was consumed in the march of the two armies, and night found them both in place, Lee's veterans planted directly across the southward course of the Army of the Potomac. There had been several collisions during the day, but no events of importance. Anderson had occupied a range of hills about a mile north and north-east of the Court-House, where he hastily intrenched, the remaining corps of the army, as they came up, falling into line with him and throwing up defensive works. This process continued during the 9th, the Union forces similarly intrenching, so that by nightfall each army was covered by a continuous line of formidable breastworks.

Grant had decided to attack on the 10th. On the preceding evening Hancock had crossed with three of his divisions the Po River, a small affluent of the Mattaponi. Two of these divisions were ordered to be recalled to take part in the designed attack. The third, Barlow's, soon found itself in a perilous position. While it was repelling a sharp attack, the woods between it and the river burst into flames, and it became necessary to fight the Confederates and the fire at the same time. The stream was recrossed, but not without heavy loss, the assailants also losing heavily. During the day two assaults were made on Lee's lines, one at 10 A. M., the other at 3 P. M. The point assailed was a thickly wooded eminence known as Laurel Hill, which was crowned with earthworks. Both attacks were repulsed with heavy loss to the assailants. At 5 o'clock the main assault began. The Second corps had now joined the Fifth, and Hancock and Warren led their men against the position which had already been twice attacked. A desperate struggle ensued. The Union lines advanced with great intrepidity, and penetrated the breastworks at one or two points. But they were met with a storm of shot and shell that flesh and blood could not withstand, and were driven back with fearful slaughter. An hour later they marched to the assault again, and were again repulsed with heavy loss. The attempt was attended with far more serious consequences to the Union than to the Confederate troops.

Nearly 6000 of the former had fallen, while the latter had lost not more than 600. The losses of the whole day's dreadful work, however, were more evenly distributed. It is stated that the total losses by death, wounds, and captivity were 9000 Union and 8000 Confederate troops.

Thus ended the first day of the battle of Spottsylvania Court-House. Great as were the difficulties he had met and the losses he had sustained the determination of Gen. Grant was not weakened. On the morning of the 11th he sent to the secretary of war a despatch whose closing words have become historical: "I propose to fight it out on this line, if it takes all summer."

The 11th passed in preparations for another battle. Grant had determined to attack Lee's line at its right centre, which seemed a vulnerable point. We are told by Southern historians that Lee had weakened this point by the withdrawal of artillery, having reason to believe that Grant was contemplating another flanking march, and that a deserter had conveyed information of this fact across the lines. Hancock's corps was designated for the assault, and moved into the requisite position during the night. In the early morning, under cover of a dense fog, the attacking column swiftly and silently advanced towards the weakened salient, held by Johnson's division of Ewell's corps. The Confederates first knew of their danger by a sudden outburst of cheers, as Barlow's and Birney's brigades dashed upon and across the works, breaking down all opposition, and capturing Johnson and almost his entire division while unsuspectingly at breakfast. In addition two brigades under Gen. Stewart were taken, with nearly 30 guns and many colors. More than 3000 prisoners were captured. Lee's army was cut in two, and the most desperate efforts were necessary to avert irretrievable disaster.

One of the most terrible conflicts of the war ensued. Lee hurried up troops from both directions, while the flying Confederates, who had been pursued through the woods for about a mile, rallied behind a second line of breastworks and turned on their pursuers. The reinforcements from Hill's and Longstreet's corps drove back Hancock's men to the position they had captured, and heavy masses of troops pouring upon them confined them within the triangular area of the salient. On the other hand the Sixth corps was sent to the assistance of Hancock, while Warren and Burnside attacked the Confederate lines along their whole front. These lines, however, were so strong that, despite the attack, their defenders could spare men for the central struggle. Here the fight was furious and sanguinary. Lee was determined to retake the lost portion of his works, and hurled all the force he could gather on Hancock. The battle was hand-to-hand; both parties at times planted their flags on the breastworks within a few feet of each other. The carnage on both sides was dreadful, but despite Lee's persistence all his efforts were in vain. He continued to fight till after night had fallen, when he withdrew his shattered columns, leaving Hancock in possession of the works he had captured.

Thus ended the battle of Spottsylvania Court-House, one of the most desperately contested and sanguinary of the war. The losses during the campaign, from the crossing of the Rapidan to the close of the battle just described, were, according to the official report, 29,410 men killed, wounded, and missing. The Confederate loss is not known. It was less severe than the Union, in consequence of their defensive attitude and the strength of their intrenchments, but was severe, and probably greater in proportion to the disparity of forces than the Union loss. Lee could not as well as Grant afford to have his army depleted. On the morning of the 13th he withdrew his troops behind an inner and shorter line of intrenchments. His position seemed as strong as ever, and Grant hesitated to attack, confronting the enemy till the 18th, on which day an unsuccessful

ful attempt was made to carry a portion of the Confederate works. The repulse of this column was avenged on the succeeding day by a similar repulse of Ewell, who had been sent by Lee to demonstrate against the Union right, under the belief that another flanking movement was in progress. Ewell was repulsed, with a loss of about 900 men.

During these events the cavalry, under Gen. Sheridan, had made a dash on Richmond. The North Anna was crossed on the 9th, much railroad property and military stores destroyed, and on the 11th some Confederate cavalry under Gen. Stuart was encountered a few miles north of Richmond. A sharp fight ensued, in which the Confederates were routed and their general mortally wounded, the latter a severe loss to their cause, since Stuart had proved himself one of the ablest cavalry leaders of the war. Sheridan pushed on and attacked the defensive works of Richmond, but found them too strong and too well defended for success in a cavalry charge. He leisurely returned and rejoined the army on May 25.

Meanwhile the army was in motion. On the 20th it disappeared from the front of Lee's army, and began a flank march to turn the position of Spottsylvania. It had sent its sick and wounded men and its prisoners to the rear, received abundant reinforcements and supplies, and moved jubilantly forward, restored to its original strength. The movement was hardly begun before Lee was aware of it and had put his own army in motion. Once more a race between the two armies began, in which Lee, having the shorter line, had the advantage. The point aimed for was Hanover Junction, an important railroad intersection, on the south side of the North Anna River. Lee occupied this position on the 22d, immediately threw up defensive works, and when Grant arrived on the 23d, it was to find his antagonist again in his front, strongly intrenched, and with a river as part of his line of defence. Lee's army occupied a singular position. Its centre touched the stream while both wings were thrown back at an obtuse angle, facing the corps of Warren and Hancock respectively. This put Grant at a decided disadvantage, for after his two wings had crossed the stream they were isolated from each other, and to reinforce either wing from the other it was necessary to make a double passage of the river. Lee's army, on the contrary, lay compactly behind its intrenchments. Despite this disadvantage Grant at once attempted to force his antagonist from his path. Warren, on the right, reached the river at an unguarded ford, and crossed without opposition. Ere he had advanced far, however, he was attacked by a strong Confederate force, and a severe conflict ensued, which ended in the repulse of the Confederates with the loss of nearly a thousand prisoners. Warren at once proceeded to intrench his chosen line without further opposition.

Hancock crossed on the left, but not with the same ease. A division of Longstreet's corps held the river at this point, occupying the bridge and a redan-shaped battery in front of it. This battery was stormed and taken, and during the night the Confederates attempted to burn the bridge. Failing in this, they withdrew from their advanced works to a stronger position in the rear, and Hancock crossed in the morning without opposition. At the same time Wright crossed above and joined Warren's corps. Burnside, in the centre, endeavored to cross, but without success.

The position of the Army of the Potomac was a perilous one. Its two wings were on the south side of a river difficult to cross and liable at any moment to a sudden swelling by rains, while the weaker centre lay north of the river. Lee's army lay between the two wings, isolating them from each other, and holding the river so strongly in front of Burnside that he was unable to cross. For two days the armies lay thus facing each other, when Grant, evidently considering that it would be madness to risk a battle under such disadvantages of position, secretly withdrew his forces to the

north of the river on the night of the 26th, and put his army in motion on another flanking movement. This march was made well to the eastward, so as to avoid a blow on the flank, its objective point being the passage of the Pamunkey, an affluent of the York formed by the junction of the North and South Anna Rivers. Possession of this point would give Grant an excellent water base of supplies at White House, while forcing Lee to abandon the line of the rivers named.

Sheridan led the way with the cavalry in this movement, and was rapidly followed by the infantry, the Pamunkey being reached and crossed on the 28th, at Hanover town, about 15 miles from Richmond. Lee had at the same time abandoned his works on the North Anna, and marched quickly southward by the shorter line, and awaited Grant on the Totopotomoy, near Mechanicsville. There had been a cavalry struggle in this vicinity on the 28th, Sheridan driving back Hampton and Fitzhugh Lee, who lost nearly 800 men, his loss not being more than half that number. On the 30th the advancing infantry came into contact with Lee's forces, and some sharp fighting took place, with no decisive advantage on either side. Grant, deeming it injudicious to make a direct attack on Lee's front, moved slowly by his left flank towards the Chickahominy, while Lee kept pace with him by a similar movement to his right, confronting him at every stage. This movement continued till a flank of each army rested upon the Chickahominy, both armies protecting themselves with breastworks at every point of the movement. They were now on the old battle-field of Gaines' Mill, where so fierce a struggle had taken place in 1862. (See PENINSULAR CAMPAIGN.) For the details of the battle which succeeded, and the conclusion of Grant's overland march to Richmond, see COLD HARBOR. (C. M.)

WILKES, CHARLES (1801-1877), naval officer and explorer, was a nephew of the celebrated John Wilkes, of England, and was born in New York city. He entered the U. S. navy as a midshipman in 1818, and served five years on the Mediterranean and Pacific squadrons. In 1826 he became a lieutenant, and in 1830 was assigned to the department of charts and instruments, where his bent for science was exercised. In 1838 he received the important appointment of commander of the U. S. Exploring Expedition, for which great preparations were made. With six vessels well equipped and an able staff of officers (Prof. J. D. Dana being the geologist and mineralogist) he sailed from Norfolk, Va., Aug. 18, and visited Madeira and the Cape Verde Islands. Touching South America at Rio de Janeiro, he coasted down the Atlantic and up the Pacific as far as Callao, and thence crossed the ocean to Australia, stopping at the Samoan Islands and sundry other groups. In December, 1839, he started from Sydney on a voyage of discovery along the Antarctic Continent, as far as latitude 101 E. The Fiji and Sandwich Islands were next visited and observations taken on the summit of Mauna Loa. After examining the Californian and Mexican coasts in 1841, the expedition sailed for Borneo and the Cape of Good Hope and returned to New York June 10, 1842, after nearly four years at sea. Charges were soon preferred against Wilkes by some of his subordinates; he was court-martialled, acquitted, and promoted to commander the next year. His memorable *Narrative of the expedition*, one of the most notable of government publications, came out in six quarto volumes in 1845, yet material remained for more. An abridgment appeared in 1851, a volume on *Western America* in 1849, and one on the meteorological observations of the expedition in 1851. The London Geographical Society honored Wilkes with a gold medal in 1848, in recognition of the gains to science through his labors; of these there was in general but one opinion, though some of his observations on the Antarctic Continent were afterwards contested by those of H. M. S. *Chal-*

lenger. He was made captain in 1855, and the next year published *Theory of the Winds*. After many years of special duty at home the outbreak of the rebellion brought him again to the front, and afforded an opportunity of supposed service and abundant distinction of which he was just the man to avail himself. He was in the West Indian waters in search of the Confederate cruiser *Sumter*, when, in the Bahama Channel, he came upon the British steamer *Trent*, carrying the mails and having on board as passengers two commissioners of the Confederate States, Mason and Slidell, accredited respectively to France and England. Valuing the end far above the means, and taking the law into his own hands, he promptly overhauled the vessel, Nov. 8, 1861, disregarding all protests, took from her the Confederate officials and conveyed them to the North as prisoners of war. No early event of the conflict caused greater sensation. In the fervor of patriotic feeling legal questions were apt to be overlooked. Wilkes was loaded with demonstrations of popular applause and received the thanks of Congress. But in England his action was regarded in a very different light; the British ministry inclined to make a declaration of war for the outrage on its flag, but Prince Albert is said to have caused the way to be left open for reconsideration by the American government. It was plain on reflection that international law had been violated with however praiseworthy intentions. The U. S. government bowed to necessity and released the commissioners, and Secretary Seward, by an adroit stroke of diplomacy, represented Great Britain as having acceded to the application of international law long insisted upon by America. Yet Wilkes did not suffer, but was presently made a commodore in 1862. Placed in command of a flotilla on the Potomac, he destroyed City Point, Aug. 28. In 1863 he was busy along the Southern coast in enforcing the blockade and capturing blockade-runners. He was retired July 25, 1866, with the rank of rear-admiral. He died at Washington, Feb. 8, 1877. A hero is nearer to the public heart than a scientist, and Wilkes' great services to geographical and other knowledge hardly made him so famous as the momentary deed of a patriotic but reckless impulse, which might have involved ruinous consequences to his country had it not been quietly but practically disavowed by the cooler heads of his superiors. (F. M. B.)

WILKINSON, JAMES (1757-1825), for some years commander-in-chief of the U. S. army, was born in Charles co., Md., and at 18 was a captain in the Revolutionary war. He served under Arnold and Gates, became adjutant-general to the latter, and carried to Congress the tidings of Burgoyne's surrender. He was to some extent involved in the Conway cabal, and left the army as a colonel in 1778, but the next year was appointed clothier-general to it. Going into business in Kentucky, he rendered great service to that region by opening the Mississippi to its trade; having gone to New Orleans in 1787 with a flat-boat, he managed not only to sell his cargo, but to obtain free entrance for others and for himself a contract to supply tobacco. This won him great local repute and popularity, and in 1789 Louisville sent 25 flat-boats loaded with provisions to New Orleans. His adventurous and speculative character was never above reproach; he was soon accused of complicity with Spanish intrigues in Kentucky, then disaffected. He took part as lieutenant-colonel in the expedition against the Indians on the Wabash, was commissioned brigadier-general in March, 1792, and commanded the right wing of Wayne's army at the Maumee, Aug. 20, 1794. He was commander-in-chief, 1796-98, and again, 1800-12, though laboring under constant suspicions and accusations of the gravest nature. He was one of the two commissioners who received the cession of Louisiana from the French in 1803, and in 1805-6 was its territorial governor. At this time he was charged, not without apparent reason, with corruption and

complicity with the treasonable plans of Burr, with whom he had sustained close relations and conducted a correspondence in cipher. The charges were embodied by Daniel Clark, of New Orleans, in an octavo volume of 349 pages (1809). The inmost facts of this connection and the general's real motives are matters of conjecture; but he suddenly assumed an attitude of vehement and energetic loyalty, put Burr's agents to the question, arrested certain persons as conspirators, sent a report to Pres. Jefferson in October, 1806, and made vigorous preparations to repel any hostile or insidious attack. The affair made a great stir, not only on the spot, but throughout the country and at the seat of government, where it presently became a party issue. Jefferson and his followers defended Wilkinson, while the Federalists accused him of illegality and abuse of power in the arrests. Randolph denounced him in Congress, and was challenged to a duel in 1808. Wilkinson's conduct was a burning question for four years; he was indicted by the grand-jury, investigated by two committees of Congress, and tried by a court-martial, in which Taney pleaded his cause and procured an acquittal in 1811. After this he went back to New Orleans, improved the defences of the city, and came into collision with Jackson. He received a major-general's commission in March, 1813, reduced Mobile the next month, and in May went to the Canada border, where he accomplished nothing. His movement on Lake Champlain in 1814, through lack of co-operation between himself and Wade Hampton, was such a fiasco that he laid down his command and asked for a court-martial, by which he was again acquitted. At the reorganization of the army in 1815 he was not included, but received a pension from Maryland, which adhered to him as a favorite son. Disgusted with the ingratitude of republics, he put forth his own side of the story in *Memoirs of My Own Times* (3 vols., 1816), purchased an estate near the city of Mexico and spent his latter years in self-imposed exile, dying there Dec. 28, 1825. His large volumes are vigorously written and show no mercy to his numerous enemies, but documentary evidence has been published which establishes his guilt. See Gayarré's *History of Louisiana: Spanish Domination* (1854).

(F. M. B.)

WILL in law denotes the disposition of one's property to take effect after death. Wills See Vol. XXIV. are usually written, yet they may be p. 570 (p. 600) unwritten or nuncupative. To make Am. Rep.). a valid nuncupative will, the person must be *in extremis* and in immediate prospect of death. In England the power of making such a will is restricted by statute to soldiers in military service, *i. e.*, on an expedition, and sailors at sea. In some of the United States these wills are specially restricted by statute, while in others they exist as they did in England previous to the limiting statute, *i. e.*, confined to a small amount of personal estate. Wills written in pencil have been held valid.

The Testator's Capacity.—He must be of the age of discretion, which is fixed by statute in England and in most of the United States at twenty-one years. Under the common law in England aliens could not devise real estate, but in the several States this has been altered by statutes. Formerly married women did not have testamentary capacity, but, together with most other of their disabilities, this has very generally been removed by statutes. In the case of wills of persons who are blind or deaf and dumb, there must be proof that the testator understood the contents of the will and communicated with the witnesses. Idiots are wholly incapable of executing a will; so also are lunatics, except during a lucid interval allowing the exercise of memory and judgment. It has been held that mere weakness of understanding will not invalidate a will, if the testator were capable of comprehending the object in view. Delirium, whether from disease or stimulus, while the paroxysm continues to

such an extent as to deprive a person of the right exercise of reason, is a sufficient impediment to the execution of a will. It differs from ordinary insanity, however, in that there is no presumption of its continuance. Senile dementia, or loss of mental faculties through old age, if shown, will also invalidate a will. If, however, the testator has sufficient memory left to collect the elements of the transaction, *i. e.*, the amount and kinds of his property, the number of his children, etc., and to form an understanding judgment concerning them, he has proper testamentary capacity, though his mind be not so strong as it once was. Fraud or undue influence, by which a person is induced to make a will, will invalidate it.

The Mode of Execution.—The statutes of the States differ as to the number of witnesses required. In Connecticut, Florida, Georgia, Maine, Maryland, Massachusetts, Mississippi, New Hampshire, South Carolina, and Vermont, three witnesses are required. In most of the other States two are sufficient, though in some the number is not specified. As a general thing the witnesses must sign in presence of the testator, and should not be interested parties. The testator may sign in their presence or may produce the instrument already signed, and acknowledge his signature in their presence.

Revocation.—A will may be revoked by the testator effacing his signature thereto, or by an evident attempt on his part to destroy it. The same capacity is requisite to revoke as to make a will. Moreover, the making of a new will purporting to be testator's last will, and containing no reference to any other paper, and being a disposition of all the testator's property, and so executed as to be operative, will be a revocation of all former wills, notwithstanding that it contains no express words of revocation. A will is revoked by the subsequent marriage of the testator and the birth of issue. This is generally regulated in the different States by statute.

Republication.—As a general rule a will revoked can only be republished by an instrument of as high a nature as that which revoked it, *e. g.*, a will revoked by written declaration cannot be republished by parol; such a republication has, however, been allowed in Pennsylvania.

Probate.—A will must be proved in the probate court. In England the probate of a will is not evidence in regard to real estate, but in the United States the probate courts have, as a general thing, exclusive jurisdiction of wills and estates, whether the property be real or personal. The probate of wills passing realty is governed by the law of the place where it is situated; of personalty by the law of the testator's domicile. Any one interested in a will may compel probate of it by application to the probate court, who will summon the executor or person having the custody of it. The witnesses must appear and prove the authenticity and execution of the will and the competency of the testator. If, however, they are absent from the State, deceased, or disqualified, their handwriting must be verified. Wills more than thirty years old, appearing regular and perfect and coming from proper custody, are said to prove themselves. Wills lost, mislaid, or stolen at the time of the testator's death may be admitted to probate upon proper proof of the loss and execution. In most of the United States there are statutes providing for the probate of foreign wills by exemplified copy.

As a general rule a will is said to speak from the death of the testator, unless a contrary intention be very plainly indicated.

Parol evidence is admissible to show the state of the testator, the nature and condition of his property, his relation to the contestants, and all the surrounding circumstances. It is inadmissible to supply any word or defect in the will or to indicate the testator's intention, which is to be gathered from the language of the instrument alone. As a general rule where a

wrong name has been inserted by the scrivener, parol evidence is not admissible to carry into effect the testator's intention, though the contrary has been held in some instances. Where there are portions of a will wholly incapable of standing with other portions, generally speaking the later provision will control, as being the latest declaration of the testator's intention.

(T. B.)

WILLARD, EMMA HART (1787-1870), educator, was born at Berlin, Conn., Feb. 23, 1787, the youngest but one of seventeen children. She entered upon her vocation at seventeen, was invited to Westfield, Mass., in 1807, soon removed to Middlebury, Vt., and there was married in 1809 to Dr. John Willard, State marshal. His fortune becoming impaired five years later, she reopened her school and by degrees introduced new studies. Her plans for the higher education of girls, previously little thought of, were so extensive as to require State aid and practically to aim at a college. They were laid before Pres. Monroe, and, in an *Address to the Public*, 1819, before the New York Legislature. In that year her school was removed to Waterford, N. Y., chartered, and promised public help, of which little came. She was induced to remove to Troy in 1821 by the offer of a large building and other facilities. Over 300 pupils entered at once, and the seminary became famous. For 17 years she conducted it with eminent success, aided by able teachers, especially her younger sister, Mrs. Almira Lincoln (afterwards Mrs. Phelps), who was with her 1823-32. Her series of text-books began in 1822 with a *Geography*, and was continued in sundry publications of which over a million had been sold at her death. Her *History of the United States*, called by another name in its first edition 1828, was translated into German and Spanish and much used by Daniel Webster. Her *Universal History* was very widely circulated. Her *Poems* (1830), suppressed by her, contained the familiar lyric "Rocked in the Cradle of the Deep;" Lafayette shed tears at another in his honor, 1825. A foreign trip in 1830-31 furnished material for a *Journal and Letters* (1833), the profits of which went to found a missionary school at Athens. Dr. Willard died 1825, and in 1838 his widow gave up her school and contracted an unfortunate marriage from which she was released by a divorce. After this she travelled much, took part in educational conventions and the like, and published treatises on *The Circulation of the Blood* (1846), and on *Respiration* (1849); *Last Leaves of American History* (1849); an *Autobiography* (1853); *Morals for the Young* (1857); and *Via Media* (1862). The last followed sundry efforts to avert the civil war, wherein she overrated her influence. She died at Troy, N. Y., April 15, 1870. Her *Life* was written by Dr. John Lord (1874).

WILLARD, FRANCES ELIZABETH, noted for her temperance work, was born near Rochester, N. Y., Sept. 28, 1839. Her parents removed to Wisconsin and she was educated at the Milwaukee and Northwestern Female Colleges. She taught in several schools and academies and contributed to various journals. While teaching in the Pittsburg Female College in 1863 she wrote a memoir of her sister under the title, *Nine Beautiful Years*. In 1868 she went to Europe and spent eighteen months there. On her return she began lecturing on reform in women's education, and in 1871 she was made president of the Women's College at Evanston, Ill. In 1874 she was made secretary of the Women's Christian Temperance Union, and in 1876 she assisted Mr. Dwight L. Moody in his evangelistic work. In 1878 she became chief editor of the *Chicago Evening Post*, but afterwards resigned to devote all her time to temperance work. As president of the Women's Christian Temperance Union she has travelled through the country addressing legislatures and people in behalf of temperance and prohibition.

WILLIAM II., emperor of Germany and king of

Prussia, eldest son of the crown-prince of Prussia (afterwards Emperor Frederick III. of Germany) and Victoria, princess-royal of England, was born Jan. 27, 1859, and succeeded to the throne June 15, 1888, on the lamented death of his father after his brief reign of 99 days. His full name is in German Friedrich Wilhelm Victor Albert. He received his early education, military as well as literary, from tutors at home, and in 1874 entered the gymnasium of Cassel, where he studied till his graduation in 1877. He was then assigned to the 1st regiment of foot-guards, in which he completed his military training under the professors of the Potsdam military academy, and was soon made colonel of the hussars of the guard, of the 1st Pomeranian regiment of grenadiers, and of the 2d Landwehr regiment of grenadiers. On Feb. 27, 1881, he married the Princess Augusta Victoria, daughter of the deceased Duke Frederick VIII. of Schleswig-Holstein, by whom he has four sons, the eldest, the present crown-prince, having been born May 6, 1882. During the last illness of his grandfather, Emperor William I., the present emperor (in the absence of his father in consequence of the malady of which he died) acted as the aged monarch's representative, and at his obsequies again took the place of his father, of whom he afterwards continued to be the representative on important occasions.

On the present emperor's accession the political sky of Europe was much overcast. Both France and Russia seemed to be preparing for war, and Germany responded in the end of 1887 by an augmentation of the Landwehr and other reserve classes of her army through extending the age of service, so that she was in a condition to place 3,850,000 men in the field, while in February, 1888, a further warning was given to the suspected powers by the simultaneous publication of the Germano-Austrian treaty—defensive and offensive—to which Italy shortly after gave in her adhesion. In such conditions the military predilections of the emperor and his supposed strongly pronounced character were regarded with widespread anxiety. His first public act was an energetic address to his army and navy. This was followed by an address to his people in which he pledged himself to walk in the paths of his just and peace-loving father. The Reichstag met on June 25, and was opened by William with much pomp. In his speech from the throne he declared himself resolved "to live at peace with all men so far as in him lay." On June 27 the new king took the oath to the constitution before the Prussian Landtag and again declared for a pacific policy. In July and August he paid visits to the northern courts of Europe—Russia, Sweden, and Denmark. In the beginning of October he visited the court of Vienna, whence he proceeded to Rome on a visit to King Humbert of Italy. Before going to the Quirenal he waited on the pope, and his Catholic subjects drew good auguries from this. In September there appeared in the *Deutsche Rundschau*, excerpts from the diary kept by his late father during the eventful epoch of 1870–71, by which it was made to appear that the consolidation of Germany into an empire was due in a much higher degree to the late emperor than to Prince Bismarck, to whom the original conception had been accredited. These extracts are said to have been given by a confidant of Emperor Frederick to Professor Geffcken, who communicated them to the *Rundschau*. The emperor, and Prince Bismarck especially, were seriously offended by the publication. Prof. Geffcken was cast into prison but was finally released, though he had been threatened with trial for high treason, the revelation of state-secrets being a treasonable offence in Germany. Even the ex-empress became the object of obloquy as having connived at the publication. She had returned to her mother in England in November, 1888, and her son appears estranged from her and full of antipathy to England and English customs. In Germany this is

popularly accounted for by saying that he attributes the malformation of his left arm, which is shorter than the other and hangs listlessly by his side, to his having been brought unskilfully into the world by an English accoucheur recommended by Queen Victoria.

It is yet too early to speak with confidence of William II.'s policy and character as a ruler. From measures announced as about to be submitted to the diet in behalf of industry and of the working classes, it is inferred that he is opposed to socialistic schemes. His foreign policy is indicated by his choosing for his special confidant his war-minister, Count Herbert Bismarck, son of his great chancellor, Prince Bismarck.

A somewhat severe ear trouble prevented him from appearing much in public during the latter part of 1888. The emperor's personal appearance is in his favor. He stands nearly six feet high and is well built, though inclined to stoutness. In complexion he is a fair blonde, though his hair inclines to a darkish brown. His features are regular and prepossessing, the eyes blue and honest and capable of smiling when he is pleased, his mouth small, and nose demi-Roman. When he stands, his left hand rests quite naturally on the hilt of his sword, so that an onlooker would not readily detect the deformity; when he sits, it hangs in seemingly soldierly fashion by his left side. Some critics accuse him of coldness and unattractiveness of manner and an aggressive bluntness in speech and action with little regard to the feelings of others.

WILLIAMS, SAMUEL WELLS (1812–1884), sinologue, was born at Utica, September, 1812. He was educated at the Rensselaer Institute, Troy, N. Y., and went to China in 1833 as a printer for the American Board of Commissioners of Foreign Missions. He was engaged at Canton in printing and editing, and also visited Japan for the same purpose. From 1845 to 1848 he resided in the United States teaching. In 1853 he was made interpreter to Commodore M. C. Perry's expedition to Japan, and rendered most valuable service. In 1855 he became secretary and interpreter of the American Legation at Peking, where he assisted U. S. Minister W. B. Reed in negotiating the treaty of 1856. Returning to the United States finally in 1876, he was appointed lecturer on Chinese at Yale College, and became president of the American Bible Society in 1881. He died at New Haven, Feb. 17, 1884. Of his various text-books and dictionaries, published in China, the most important is the *Syllabic Dictionary of the Chinese Language* (1874). He is best known by *The Middle Kingdom* (1848; but greatly improved, 2 vols., 1883). He also published *Chinese Immigration* (1879). See his *Life* by his son, F. W. Williams (1889).

WILLIAMSON, HUGH (1735–1819), scholar and statesman, was born in West Nottingham, Pa., Dec. 5, 1735. His parents were Irish. After graduating at the College of Philadelphia 1757, he studied theology, was licensed to preach and admitted into the Philadelphia Presbytery, but was never ordained, and soon turned to secular pursuits. His abilities and tastes were of such varied character that he found it difficult, if not impossible, to concentrate on any one field of activity; and, indeed, he attained distinction in several which had little natural connection. He was professor of mathematics in the College of Philadelphia 1760–3, then turned to medicine, and went abroad in 1764 to study at Edinburgh, London, and Utrecht. Returning to Philadelphia, he entered upon successful practice, but his own health became impaired. Cultivating astronomy and other sciences, he made observations on the transits of Venus and Mercury in 1769, and studies of climate in 1770: these were inserted in the *Transactions* of the Philosophical Society. He went to the West Indies in 1772, and the next year to England to solicit funds for an academy at Newark, Del. The political feeling against the colonies prevented success for such a mission. Questioned before the Privy Council in February,

1774, as to the state of things in America, he told the story of the destruction of the tea at Boston, and frankly said that war was probable if the policy of coercion were not abandoned, at which Lord North expressed much surprise. The tale of his obtaining the Hutchinson letters, though long believed and often repeated, has been disproved. After his return he entered into business, removed to Edenton, N. C., and during the war served as an army surgeon, and was sent to the legislature. He was a member of Congress 1782-5 and 1787-8, and of the Constitutional Convention in 1787: at home he pleaded the cause of the Constitution, and bore a part in bringing North Carolina into the federal Union. In 1793 he removed to New York, where he attained a conspicuous place as a citizen and scholar. He contributed to the *American Museum* and to the *Transactions* of several learned bodies, wrote upon comets and canals, and delivered an address before the New York Historical Society in 1810 on *The Benefits of Civil History*. His *Observations on Climate* (1811) had a patriotic object—to defend America from the aspersions of certain foreigners in this respect—and received praise from Jefferson. His *History of North Carolina* (2 vols., 1812) added less to his reputation. He died in New York, May 22, 1819. A *Memoir* of him by Dr. Hosack is preserved in the *Collections* of the New York Historical Society.

WILSON, DANIEL, Canadian scientist and archaeologist, was born in Edinburgh, Scotland, in 1816. After a full course of study in its High School and University, he went to London to engage in literary work, but soon returned to his native city. Here his devotion to archaeology procured for him the appointment of secretary of the Scottish Antiquarian Society. In 1843 he removed to Canada, where he was made professor of history and English literature in University College, Toronto. In Canada Dr. Wilson found a wide field for his favorite researches, while he also devoted himself assiduously to his academic duties. In 1881 he was chosen to be executive head of the college. His first publication was *Memorials of Edinburgh in the Olden Time* (2 vols., 1847), and, after an interval of thirty years, he produced a similar work, *Reminiscences of Old Edinburgh* (1878). His more ambitious work, *The Archaeology and Prehistoric Annals of Scotland* (1851; 2d ed., 1863), won the praise of Hallam as the most scientific treatment of the archaeological evidences of primitive history ever written. Yet this work was only preparatory to his greater achievement, *Prehistoric Man: Researches into the Origin of Civilization in the Old and the New Worlds* (1863). Its later editions have been considerably rewritten, but it still stands conspicuous not only for scientific value but for grace of literary style. Besides these archaeological works, Dr. Wilson has published *Chatterton: a Biographical Sketch* (1869); *Caliban, the Missing Link* (1873), and *Spring Wild Flowers*, a volume of verse. He has also contributed to the *Proceedings* of antiquarian, anthropological, and other scientific societies. The Marquis of Lorne, in instituting the Royal Society of Canada, nominated Dr. Wilson its vice-president. To the ninth edition of the *ENCYCLOPÆDIA BRITANNICA* he has contributed not only the articles on "Canada" and "Toronto," but even that on "Edinburgh," besides biographical notices of "Ferguson" and "Chatterton." Dr. Wilson still lives in the city of his adoption and discharges the duties of his professorship.

WILSON, JAMES (1742-1798), signer of the Declaration of Independence, was born near St. Andrew's, Scotland, and passed from the University of that place to those of Glasgow and Edinburgh. Having finished his studies, he crossed the sea about 1763, and taught for a time in the college at Philadelphia. He and William White, afterwards bishop, became friends, and wrote in company some essays called *The Visitant* (1767-9). After studying law under Dickinson (q. v.),

and practising for a few years at Carlisle and elsewhere, he returned to Philadelphia, and soon attained very high rank in his profession. His pamphlet on *The Authority of the British Parliament* (1774) was much praised. By this time he was a colonel of militia and member of the convention of the province. Sent in 1775 to the Continental Congress, he won repute as a scholar and debater, but did not favor independence. In February, 1776, he sought to open the ports, and offered an address to the country, which, being highly conservative in substance and spirit, met with no favor, and was not even voted on. He continued to oppose all measures of separation until the will of his constituents was declared for independence; then, July 4, he signed the Declaration with his colleagues. In the same month he proposed a tax upon slaves. The next year he was made a commissioner to treat with Indians. He defended certain Tories and merchants who refused to lower their prices to a scale proposed in popular resolutions, and by these and similar acts incurred much odium. A mob attacked his house with cannon Oct. 4, 1779; he and his friends defended it; the City Troop came to his aid, and blood was shed. He acted as advocate-general of France in the United States 1779-81, and continued to give advice for some time after; the post was more laborious and honorable than lucrative. But his gains at the bar, of which he was long the acknowledged head in his city and State, were large. He was a director of the Bank of North America from 1781, and its counsel 1785; agent for his State in 1782 in the controversy with Connecticut concerning the Wyoming tract on the Susquehanna; again a leading member in Congress in 1782 and 1786. In the Convention of 1787 he was "the best-read lawyer," and chairman of the committee which reported the draft of a constitution, August 6. His services here and afterward were perhaps more illustrious than in Congress. At the State Convention which followed he lauded the Constitution as "the best form of government ever offered to the world," and in the ceremonies which celebrated its adoption, delivered at the State House, July 4, 1788, a weighty and memorable oration. Yet as a member of a committee to harmonize the State constitution with that of the United States, he took the other side in objecting to the choice of senators by electors. Washington appointed him in October, 1789, one of the first judges of the U. S. Supreme Court. This post he retained till his death, though his talents were thought to shine more brilliantly at the bar than on the bench. One of his decisions, in a case concerning Georgia, asserted the sovereignty of the nation; in this Chief-Justice Jay and two others concurred. He received in 1790 the first appointment as professor of law at the City College, which was united with the University of Pennsylvania in 1792. Here he delivered but three courses of lectures. Appointed in March, 1791, to revise and digest the laws of Pennsylvania, he submitted in August an elaborate plan. The Senate did not concur, and he carried on the task for his own satisfaction, without authority or compensation. His later practice was chiefly in the admiralty courts. Large as were his gains, they were swallowed by the land speculations then so disastrously rife; he became involved, and to avoid arrest for debt, exchanged circuits with a Southern colleague. He died at Edenton, N. C., Aug. 28, 1798, of strangury, according to the older accounts. Prof. McMaster goes so far as to say that he "died a broken-hearted fugitive from justice." His *Works*, including his law-lectures, were edited by his son, Rev. Bird Wilson (3 vols., 1803-4).

(F. M. B.)

WINCHELL, ALEXANDER, geologist, was born at North East, Duches co., N. Y., Dec. 31, 1824. While still young he evinced a strong inclination towards what has been the pursuit of his life, and began teaching at the early age of 15. After several years thus engaged, he entered Wesleyan University, Middletown, Conn., from which he graduated in 1847.

During the two or three succeeding years he taught the natural sciences in New York seminaries, engaged in the study of botany, and in 1849 married Miss Julia Frances Lines, of Utica, N. Y. In 1850 he removed to Alabama, where for several years he had charge of institutions of learning, and continued actively his natural history studies, sending a valuable collection of plants, animals, and fossils to the Smithsonian Institution in 1853. In the same year, on the recommendation of Prof. Louis Agassiz, he was nominated professor of physics and civil engineering in the University of Michigan, and early in 1854 entered upon his duties in this institution, with which he has been so long connected. In 1855 he was made professor of geology, zoölogy, and botany, which chair he continued to fill until June, 1873.

During this period he performed other labors of importance. In 1859 he served as President of the State Teachers' Association, and edited and published the *Michigan Journal of Education*, and about the same time began that system of popular writing and lecturing on science which he has diligently kept up since. From 1859 to 1861 he occupied the position of State geologist of Michigan, and again from 1869 to 1871, acting also as director of the geological survey of Minnesota in 1870. The results of his labors in this field of duty were embodied in several volumes of reports of the surveys. They include *The Grand Traverse Region of Michigan*; a *Geological Map of Michigan*; and an *Official Geological Survey of the Salt Lands of Minnesota*, with numerous papers in scientific journals. His study of the zoölogical and palæontological material collected during the survey yielded seven new genera and 304 new species of animals, mostly fossil. During this period also he filled from 1866 to 1869 a chair in the Kentucky University similar to that occupied in the University of Michigan.

In 1872 he accepted the position of chancellor of Syracuse University, N. Y., but resigned in 1874, and during several successive years held the chair of geology and zoölogy in that institution, while lecturing on the same subject at Vanderbilt University, Tenn. In 1879 he was recalled to the University of Michigan and assumed the chair of geology and palæontology, which he still holds.

While thus actively engaged as a geologist and educator, Prof. Winchell has been an industrious writer, and, in addition to the works named, has produced a considerable number of works of popular science. His first production of this kind was *Sketches of Creation* (1870). About the same time appeared a work on *The Genealogy of the Winchell Family in America*. Later works comprise *Geology of the Stars* (1872); *The Doctrine of Evolution* (1874); *Reconciliation of Science and Religion* (1877); *Pseudomites* (1880); *Sparks from a Geologist's Hammer* (1881); *World Life* (1883); *Geological Excursions* (1884); *Geological Studies* (1886), and *Shall we Teach Geology?* (1889). In addition to the foregoing, *Walks and Talks in the Geological Field* (1886) was written for the "Chautauqua Literary and Scientific Circle."

Within recent years Prof. Winchell has been engaged on geological work under the auspices of the U. S. Geological Survey, and in the summers of 1886 and 1887 served on the Minnesota Geological Survey in the region north of Lake Superior, publishing extended reports of each year's explorations. In 1888 he was chairman of a committee to organize the American Geological Society, and became vice-president of the society when organized. Early in 1888, he, with six others, established the *American Geologist*, to whose pages he has since been an active contributor. In 1867 he received the degree of Doctor of Laws from the Wesleyan University. He has been a member of the American Association for the Advancement of Science since 1850, and is a corresponding or honorary member of most of the scientific societies in the United States and of many in Europe.

Prof. Winchell occupies a high rank among American scientists. His long continued services as an educator in advanced institutions of learning, his labors in the field as a practical geologist, the valuable reports in which his geological observations are embodied, the collections he has made and the new genera and species described, and his many works devoted to the popularization of science, constitute a vast amount of important labors, indicative of unusual industry in the field of scientific study. His works of popular science are written in a clear and interesting manner which goes far to explain their popularity, while at the same time they are of a fulness and accuracy and possess an abundant reference to authorities which are indicative of the carefulness and very wide reading of the author, and make them of value to learned as well as unlearned readers. He is a Christian scientist. While a believer in the theory of evolution, he does not consider that this is irreconcilable with the teachings of Christianity. He has done important work in the direction of harmonizing the doctrines of religion and science. Prof. Winchell contributed to this work the article on DARWINISM. (C. M.)

WINEBRENNER, JOHN. See CHURCH OF GOD.

WINES, ENOCH COBB (1806-1879), prison reformer, was born at Hanover, N. J., Feb. 17, 1806. After graduating at Middlebury College, Vt., 1827, and teaching for two years in Vermont, Virginia, and Washington, he was attached to the U. S. ship Constitution, 1829-31, and described the Mediterranean and other experiences in *Two Years and a Half in the American Navy*, 1832. He taught in a Princeton school, 1833-38, in the Philadelphia high-school, 1838-44, and at Burlington, N. J., 1844-48. After entering the Congregational ministry 1849 and holding charges in Vermont and Long Island, he was appointed classical professor in Washington College, Pa., 1853, and was president of the City University of St. Louis, 1859. His specialty was not discovered till 1862, when he became secretary of the New York Prison Association, and gave himself to its line of work. In 1870 he was transferred to a similar position in the National Prison Association, then organized at Cincinnati, chiefly by his means. In 1871 he was sent to Europe by the U. S. government to bring about an international penitentiary congress. At its meeting in London, July 4, 1872, twenty-six countries were represented, and Wines was made chairman of a permanent international committee, which after several meetings called together a second congress at Stockholm in 1877. Of this he was as before the directing and inspiring mind. His work in these later years is shown by his various reports, and in *The State Prisons and Child-saving Institutions throughout the World* (1880), which he did not live to see in print. Of his earlier books the more notable are *How shall I Govern My School?* (1838) and *Commentaries on the Laws of the Ancient Hebrews* (1853); the latter received much praise. He died at Cambridge, Mass., Dec. 10, 1879. His work in gathering the statistics of prisons, etc., has been carried on by his son, F. H. Wines.

WINLOCK, JOSEPH (1826-1875), astronomer and mathematician, was born in Shelby county, Ky., Feb. 6, 1826, and died suddenly in Cambridge, Mass., June 11, 1875. His father, Fielding Winlock, was a lawyer, and his grandfather, Gen. Joseph Winlock, a Virginian by birth, was one of the early settlers of Kentucky, and for some years a member of the State Senate. The latter having joined the American army at the outbreak of the Revolutionary war, when he was only eighteen years old, was promoted to the rank of ensign, lieutenant, and captain, and in the war of 1812 held the commission of brigadier-general. His grandson was graduated with distinction from Shelby College in 1845, and was immediately appointed professor of mathematics and astronomy in that institution. He held this position till 1852, when he went to

Cambridge to take part in the computations for the newly established *American Ephemeris and Nautical Almanac*, and remained in this service till 1856, when he was appointed professor of mathematics in the U. S. Navy. He was first assigned to duty at the Naval Observatory in Washington, but in September, 1856, was placed in charge of the *Nautical Almanac* office, in Cambridge. In 1859 he was ordered to the Naval Academy, Annapolis, as head of the department of mathematics. At the outbreak of the war in 1861 he was again appointed superintendent of the *Nautical Almanac* and held this post till he resigned from the navy in 1866 to accept the position of Phillips professor of astronomy in Harvard College and director of the observatory. Up to this time his work had been almost entirely in theoretical astronomy and in class instruction, but upon assuming the directorship of the observatory, he devoted himself to practical astronomy, to the improvement of the instrumental equipment of the observatory, and to the establishment of its time-service upon a very effective and simple plan. In the new meridian circle mounted at the observatory in 1870, he introduced a number of modifications which have been generally adopted in the large meridian circles constructed since that time. In 1869 Prof. Winlock was chief of the party organized under the U. S. Coast Survey (of which he was consulting astronomer), for observing the eclipse of the sun of Aug. 7, and he was here the first to obtain a direct photograph of the corona. In 1870 he had charge of a similar party to observe the solar eclipse of Dec. 22 at Xerez de la Frontera in Spain, numbering among his colleagues Profs. Young, Langley, and Pickering. While preparing for this second eclipse he devised the form of "photoheliograph" (see TELESCOPE) used by the American parties in observing the transits of Venus in 1874 and 1882. In August, 1874, he was appointed by Pres. Grant chief of the commission established by act of Congress for the purpose of inquiring into the causes of steam-boiler explosions, and his preparations for preliminary experiments were nearly completed at the time of his death.

Professor Winlock wrote but little. His published work is found chiefly in the *Annals of the Harvard Observatory* and among the official publications of the *Almanac* office and the eclipse *Reports of the Coast Survey*. He was a Fellow of the American Association for the Advancement of Science and of the American Academy of Arts and Sciences, a member of the Astronomische Gesellschaft, and a corporate member of the National Academy of Sciences. (W. C. W.)

WINSOR, JUSTIN, librarian, was born in Boston, Jan. 2, 1831, and received his education at Harvard and Heidelberg. He was superintendent of the Boston Public Library during 1868-77, and then became librarian of the Harvard University Library. From 1876 to 1886 he was president of the American Library Association, being the first to hold that office. Widely known as a librarian, he has also gained an enviable position as an author. His writings include *History of Duxbury, Mass.* (1849); *Reader's Hand Book of the American Revolution, 1761-83* (Boston, 1880); *Was Shakespeare Shapleigh?* (Boston, 1887); and various pamphlets on historical subjects. He has also edited the *Memorial History of Boston* (4 vols., 1880-81), the valuable *Narrative and Critical History of America*, the *Harvard University Bulletin* (since 1871); *Bibliographical Contributions*, for which he has himself furnished several valuable bibliographies of Ptolemy's Geography, J. O. Halliwell Phillips, etc.; and the *Record of the Commemoration 5-8 Nov., 1886, on the 250th Anniversary of the Founding of Harvard College* (Cambridge, 1887). He received the degree of LL. D. from the University of Michigan.

(F. L. W.)

WIRE. See ROLLING-MILLS.

WISE, HENRY ALEXANDER (1806-1876), Governor of Virginia, was born at Drummondtown, Va.,

Dec. 3, 1806. He graduated at Washington College, Pa., 1825, was admitted to the bar in 1828, and after a year or two of practice at Nashville, returned to Virginia in 1830. In the national Democratic convention of 1832 he supported the nomination of Jackson, but opposed that of Van Buren. Steering a middle course, he approved neither the doctrines of nullification nor the stern repression of them by the government. In Congress, 1833-44, he won considerable reputation as a speaker, opposed Jackson's removal of the deposits, favored Clay's nomination in 1840, and urged that of Tyler as Vice-President. After Tyler's accession to the Presidency, Wise was one of his chief friends and counsellors. Named in 1843 as minister to France, but not confirmed by the Senate, he was appointed to Brazil in 1844, and remained there three years. He was a member of the Virginia Constitutional Convention of 1850. In 1855 he was an Anti-Know-Nothing candidate for Governor, and was elected. His four years in this office, 1856-60, cover a period of great historical importance. In September, 1856, he called upon the governors of other Southern States to meet in October for consultation as to the steps to be taken in the event of Fremont's election. In 1858, as a Douglas Democrat, he sketched and attacked, in a letter to W. Sargent, the scheme of the disunionist intrigues, as carried out two years later. In February, 1861, he urged pacific measures of compromise; these failing, he soon went with his State. His career as a Confederate brigadier was a succession of disasters, ending with the capture of his forces and the death of a son at Roanoke Island, Feb. 7, 1862. His later years were spent in the practice of law at Richmond. He died Sept. 12, 1876.

WITHERSPOON, JOHN (1722-1794), president of Princeton College and signer of the Declaration of Independence, was the son of a Scotch minister at Yester, near Edinburgh, and descended on his mother's side from John Knox, whose vigor, tenacity, and combativeness he in some degree inherited. Born Feb. 5, 1722, he was educated at the University of Edinburgh, licensed to preach in 1743, and ordained minister of Beith 1745. The next year he witnessed the battle of Falkirk, was arrested with other spectators by the victors, and imprisoned in Donne Castle. His earliest honors were won in the controversies of the time, wherein he warily espoused the stricter side against Robertson and the Moderates. His first book, *Ecclesiastical Characteristics* (1753), an anonymous satire, made much stir, and was followed by a *Serious Apology*, which bore his name. An *Essay on Justification* (1756) retains fame among treatises of the high Calvinistic order. An *Inquiry into the Nature and Effects of the Stage* (1757) was aimed at Home and his tragedy of *Douglas*; the guilty author soon left the ministry. The Moderate faction in Presbytery opposed Witherspoon's preferment to the Low Church at Paisley, but he was installed in January, 1757, and shortly became moderator of the Synod of Glasgow and Ayr. Here he was prosecuted and fined for preaching against certain sinners by name. His literary career, arrested for a time, was resumed by the publication in London of his *Essays* (3 vols., 1764). He now received the degree of D. D. from Aberdeen, and invitations from Dublin, Dundee, and Rotterdam. These he declined, as also a first call in November, 1766, from the College of New Jersey (q. v.), but when this call was renewed he bade farewell to Scotland in the spring of 1768 in a volume of *Practical Discourses*. He was inaugurated as president at Princeton College Aug. 17, and began an active and fruitful administration, introducing lectures—then a new experiment in American colleges—and the study of French and Hebrew. The latter he taught himself, besides divinity, moral philosophy, and rhetoric; in addition to all this he was pastor and preacher to the town. These labors did not prevent his travelling in New England in search of funds, and seeking them in Virginia and

South Carolina, and even Jamaica, the hearts of whose inhabitants he strove to win by a published *Address*. He obtained books and apparatus, with an orrery said to be the first made by Rittenhouse. He promptly took a leading place in Presbyterian councils, and had a hand in training many of the chief ministers and laymen of that church.

Dr. Witherspoon's expansive energies found even a larger field in the American struggle for independence, in which he was as warm as any; he said he had "become an American the moment he landed." His fast-day sermon, May 17, 1776, on the *Dominion of Providence over the Passions of Men*, was dedicated to John Hancock as president of the Continental Congress, and reprinted with notes in Glasgow to show the wickedness of rebels. The war, which closed the college for a time, enabled him to devote himself to the service of the State. He was a member of the New Jersey convention called to frame a constitution for the State, and of its first Congress, which he opened with prayer. Here his gift of sarcasm was exercised upon William Franklin, son of Benjamin and royalist governor, who when arrested by the Congress strove to treat it with supercilious contempt. Witherspoon was sent to the Continental Congress June 21, and almost his first act in Philadelphia was to sign the Declaration. "The Colonies," he said, "were not only ripe for independence, but rotting for want of it." His patriotism was as solid and consistent as it was ready and outspoken. Except in 1780, when he made an effort to revive the college, he sat in Congress till November, 1782, always in clerical attire, and accounting himself "God's minister both in a sacred and in a civil sense." Already noted as a theologian, he took equal rank as a civilian, drew up many of the papers of Congress, and did his full share of work in its committees and on the floor. He was a member of the Board of War in 1777, and in February, 1781, proposed to give Congress power to regulate trade. He supported the financial measures of Robert Morris, and opposed paper issues after the second; his *Essay on Money* had solid value. His last work was *The Druid* (1781). Few civilians of the revolutionary period occupied a more prominent place in the public eye; of all the leaders of that time, after Washington, he was thought to have the most impressive presence. His important work seemed to be ended with the war. Against the advice of Franklin and Jay, he unwisely undertook in 1783-84 to solicit aid for the college in Great Britain, where popular irritation against America made the attempt useless. He yielded to the mania for land speculation, and had trouble thereby. At the age of 69 he married a lady of 23. The chief duties at Princeton in these later years were assumed by his son-in-law, the vice-president, for Dr. Witherspoon was afflicted by failing health and sight. He died at his house, "Tusculum," near Princeton, Nov. 15, 1794. His *Works* were collected in 4 vols., N. Y., 1800-1 (reprinted in 3 vols., Phila., 1803, and in 9 vols., Edinburgh, 1804). A *Life* of him by Dr. Ashbel Green remains in MS. in the library of the N. J. Historical Society. His statue was unveiled in Fairmount Park, Philadelphia, Oct. 20, 1876; the *Proceedings and Addresses* on that occasion were published in 1877.

WOLSELEY, SIR GARNET JOSEPH, VISCOUNT, an eminent British general, son of a major of the same name, was born at Golden Bridge House, County Dublin, Ireland, June 4, 1833. Educated at a private school and by tutors at home he early showed a fondness for military studies, especially engineering. He entered the army on March 12, 1852, as ensign, and went to Burma, arriving in March, 1853. He led an attack on the works of the insurgent Myntoon, was dangerously wounded, and lay six months in a critical condition. In the Crimean war he arrived before Sebastopol Dec. 5, 1854, and was under fire the next day; was actively engaged in repulsing the Russian sorties, and was posted at the right in the attack of Dec.

30. He soon volunteered as an assistant engineer, was made a captain in January, 1855, took a prominent part in the siege, serving often in the trenches, and receiving several wounds, one of which gave him trouble years after. On Dec. 30 he lost an eye and was disabled by numerous wounds, through a round shot striking a gabion close to him. Recovering he was appointed on the staff of the quartermaster-general. Of twelve officers in three messes he was the only one not killed or sent home wounded. He remained in the Crimea till the last soldier had left it. After brief service at Aldershot he was sent to India and wrecked in the *Transit*, July 10, 1857, on the island of Banca. He marched under Sir Colin Campbell to the relief of Lucknow, commanded the storming party which carried the mess-house and drove the enemy from the Motu Maheel palace, took part in the later actions with the rebels, and had charge of the quartermaster-general's department of Sir Hope Grant's division during the operations in Oude and on the Nepaul frontier. Made lieutenant-colonel in April, 1859, he went to China with the same commander, reaching Hong-Kong March 13, 1860, and took part in the expedition to the island of Chusan, which surrendered. In June he went with Grant to the north of China, and in the movement toward Peking he had charge of the topographical department, surveying the country in advance of the troops, carrying his life in his hand and twice narrowly escaping capture. He witnessed the sacking of the Summer Palace and the surrender of Peking, Oct. 15. After the embarkation of the troops he made a trip to Japan, went on a confidential mission to Nankin to inquire into the condition and prospects of the Taeping rebels, and reached England in May, 1861. He sailed in December as assistant quartermaster-general to an army of 10,000 ordered to Canada. Disregarding the orders of his government he visited in August the Confederate armies in Virginia, meeting Lee and Jackson. The succeeding years were uneventful; he became colonel in 1865. The breaking out of an old Crimean wound in the leg sent him back to England, whence he returned to command a camp of exercise in Canada, and took the field against the Fenian invasion near Niagara, 1866. In 1870 he commanded the expedition which put down Riel's rebellion on the Red River. Leaving Toronto May 21 with 1200 men, he made a road from Thunder Bay, on Lake Superior, took Fort Garry in August, restored order, installed a new governor of Manitoba, started eastward Sept. 10, and returned to England to be knighted and placed on half-pay.

Six months later he was appointed assistant adjutant-general of the Horse Guards, and was a member of Cardwell's commission for the reorganization of the army. In August, 1873, he was ordered to the Gold Coast of Africa as governor and major-general to conduct the Ashantee war. Embarking at Liverpool Sept. 12 he arrived at Cape Coast Castle Oct. 2 with 27 selected officers, and twelve days later attacked Essaman with success. After a dangerous attack of fever he received reinforcements, instructed them in bush-fighting, and marched into the interior. With 1500 English and 500 natives he defeated King Coffee Calculi at Amsapel, Jan. 31, 1874. He entered Coomassie Feb. 4, and burned and left it three days later. The king now submitted, and the treaty of Fommanah was concluded, Feb. 13. Sir Garnet sailed for England March 4, having rapidly and successfully finished this war at a cost of £900,000. At home he received the thanks of Parliament, the permanent rank of major-general, a grant of £25,000, the ribbon of the Bath, and various other honors.

He was presently made inspector-general of the auxiliary forces, and sent, February, 1875, to Natal to reform the administration and secure the defences of the colony. After acting as governor five months, instituting many reforms, he returned to England in October and resumed his duties at the war office. In

November, 1876, he accepted a seat in the Council of India. While war with Russia threatened, 1877-78, he was chief of staff to Lord Napier of Magdala, who was in command of the expeditionary army. Cyprus having been ceded by Turkey to Great Britain, he sailed July 15, 1878, as high commissioner and commander-in-chief of that island, where he reformed the administration. He predicted the Zulu war, and in June, 1879, was sent to South Africa as governor and high commissioner of Natal and the Transvaal to reorganize Zulu affairs. The natives had been subdued at Ulundi before his arrival, but he settled the country by dividing it under a number of petty chiefs. Returning to England May, 1880, he was quartermaster-general at army head-quarters till April, 1882, when he succeeded Sir Charles Ellie as adjutant-general.

Placed in command of the expeditionary force sent to Egypt in 1882 to crush Arabi, he landed at Alexandria on Aug. 15, stormed Arabi's lines at Tel-el-Kebir Sept. 13, received his surrender, and finished the campaign without much loss, leaving Egypt Oct. 14. He again received the thanks of Parliament, was gazetted Baron Wolsley of Cairo and of Wolsley in county Stafford, and raised to the rank of general. In 1883 he received the degree of D. C. L. from Oxford, and that of LL. D. from Cambridge and Dublin. In 1884 he was again sent to Egypt as commander-in-chief to direct the expedition for the relief of Khartoum and Gen. Gordon. This was a task greater than had previously been laid upon him, and perhaps beyond human skill; at any rate his previous successes were not now repeated. Leaving England Aug. 30 he went up the Nile, and by Dec. 31 had a large force at Korti. Sir H. Stewart was sent across the desert to Metemuch, which he found too strong to be attacked. Sir Charles Wilson went up the Nile by steamer, but learned of the fall of Khartoum and the death of Gordon, Jan. 28, 1885. This disaster changed the aspect of affairs. Lord Wolsley, feeling that Khartoum should be retaken, but unwilling to exceed his limits of responsibility, sent to England for instructions, and received orders to retire upon Korti. Gen. Earle had meantime advanced up the Nile, but was killed, and Col. Brackenbury withdrew his troops. By the end of May the British forces had retired to the frontier of Upper Egypt. This somewhat inglorious campaign appeared to demonstrate the inability of European armies to cope with a large and organized force of Arabs on their native sands of the remote Soudan. The Mahdi has never been overthrown, and Gordon is still unavenged. The commander, though much criticised, was sustained by the government and by general opinion. Returning home he was a third time thanked by Parliament, and made K. P. and Viscount Wolsley of Wolsley, county Stafford.

He is still adjutant-general to the forces, and represents the modern school of the British army. His many accomplishments and honors afford a natural mark for detraction; he has been sneered at as a skillful concocter of despatches, a courtier, politician, and carpet-knight. To such accusations the facts of his life are a sufficient answer. He has published *A Narrative of the War in China* in 1860 (1862); *Soldier's Pocket-Book for Field Service* (1869), which has been called "invaluable" and has reached a fourth edition (1882); *System of Field Manœuvres, in Essays for the Wellington Prize* (1872); *Field Pocket-Book for the Auxiliary Forces* (1873); and various contributions to periodicals, among them *France as a Military Power in 1870 and 1878* in the *Nineteenth Century* for January, 1878. His *Life* was written by Charles Rathbone Low (1878).

WOMEN, LAW RELATING TO. In the United

See Vol. XXIV, p. 633 (p. 673 Am. Rep.).

States the national government, being a government of ceded powers, has no power by legislation to determine the status of the citizens of the several States or of its own citizens resident within the

States, or to make laws governing the rights of real or personal property situate within the States; hence there can be but little national legislation in regard to women. Each State makes laws governing the status of its own citizens and of the United States citizens resident therein, also of property located within its borders, the only restrictions upon State legislation upon this or any other subject exclusively within the jurisdiction of the State governments being that it shall not be in conflict with the United States Constitution and the laws made in pursuance thereof. From this peculiar construction of the United States government the laws in regard to women, their personal and property rights, are not uniform throughout the United States.

1. *Law of the United States.*—Amendment XIV., Section 1, of the United States Constitution declares that "All persons born or naturalized in the United States and subject to the jurisdiction thereof are citizens of the United States and of the State in which they reside. No State shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any State deprive any person of life, liberty, or property without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws." Amendment XV. declares that "The right of citizens of the United States to vote shall not be denied or abridged by the United States or any State on account of race, color, or previous condition of servitude," and Section 2 of Amendment IV. provides that "The citizens of each State shall be entitled to all privileges and immunities of citizens in the several States."

Under these provisions of the United States Constitution no State can, by its legislation or by constitutional amendment, deprive women resident within its borders, either native-born or naturalized by the naturalization laws of the United States, of citizenship of the United States and of the individual State in which they reside nor of the "essentials" of such citizenship.

But what are the essentials and rights of citizenship has been the subject of judicial construction in both the Federal and State courts, and notwithstanding the express recognition of the "right to vote" as a right of the United States citizens, given in Amendment XV. of the national Constitution, it has been held that although all United States citizens are capable of becoming voters, the right to vote is not a right, immunity or essential of citizenship, and that the States may so regulate its exercise as to determine what class of inhabitants may vote, and may deny this right on account of sex and upon all grounds except race, color, or previous condition of servitude, an anomalous construction of the fundamental law of a government whose existence depends upon the exercise of the elective franchise by its citizens.

A similar construction has been given as to the civil rights apparently guaranteed to all citizens of the United States by these constitutional provisions; hence in general terms it may be stated that the political and civil rights of women citizens of the United States are determined not by the Constitution and law of the United States, but by the constitution and law of the State in which they reside, and are indices of the progressive intelligence of the States. The subject of naturalization being exclusively within the jurisdiction of the general government, the naturalization laws are national and provide for the naturalization of women aliens, either upon direct application or as wives and children of naturalized citizens; also as children of native-born citizens resident abroad, that is, outside of the jurisdiction of the United States, at the time of their birth.

As citizens of the United States women may be commissioned by the general government as post-mistresses, U. S. marshals, captains of steamboats, surgeons in the army, nurses and matrons in governmental

hospitals, clerks in the several departments of government, and by special act of Congress women may be commissioned as attorneys-at-law of the Supreme Court of the United States. Her right to a commission as an attorney-at-law of the Circuit and District Courts of the United States depends upon the provisions of the law of the State in which such court holds its sessions. Women citizens of the United States may also pre-empt lands under the laws of the general government. They are counted in the basis of representation, both in the State and national governments, and are subject to the general laws governing taxation; are capable of committing treason and for treasonable acts are held responsible to the general government.

2. The State Law.—The characteristic difference in the personal rights of men and women in the United States consists in the enjoyment of political rights by the former. In every State and Territory of the United States every man not convicted of an ignominious crime is a voter or capable of becoming a voter, clothed with all political rights, and eligible to the highest office in the government, if he be native-born, although in many instances exempt from many of the corresponding political duties of citizenship, while women are very generally deprived of political rights. From this deprivation of political rights arise all the legal disabilities of women in the United States which are not incident to the marriage relation under the common law of England. Each State has the power to extend the right of suffrage to its women citizens, either by constitutional amendment or by virtue of a constitutional provision already existing—as in Wisconsin and Colorado—by a majority vote of its qualified electors at any general election; also by a three-fourths vote of the States the national Constitution may be amended so as to secure to women throughout the United States the right to vote. Strenuous and continued efforts have been made to secure these constitutional amendments, and it is believed that soon women in the United States will be very generally clothed with political power.

Already in the Territories of Wyoming, Washington, and Utah women vote, serve upon juries, and are eligible to office; in short, are clothed equally with men with full political rights, and are subject to the corresponding political duties of citizenship.

In Kansas women have equal suffrage upon all municipal questions and at all municipal elections, and are eligible to all municipal offices—absolutely filling the office of mayor of the municipality in several instances, but may not vote at Presidential and Congressional elections.

Since the adoption of Amendments XIV. and XV. to the national Constitution, the right of women citizens of the United States to vote at Presidential and Congressional elections has been tested in New York, Illinois, Missouri, California, Connecticut, and Pennsylvania. In Pennsylvania, in 1872, the right of women to vote at the State elections under the word "freemen" in the State Constitution describing the qualifications of voters in that State was claimed and resulted in a change in the State Constitution, by which the words "male citizens" were substituted for the word "freemen," thus confining suffrage to men.

Pennsylvania recognizes the right of women to direct representation upon the public school question, by making her eligible to an elective office upon the school board, thus indirectly recognizing the correlative right of suffrage. At the present time more than half of the States recognize the right of married and unmarried women to the school franchise; noted among which in the East are Massachusetts and New York.

In several instances married women have been called upon to serve upon the school board—always an elective office—and in one instance to fill the office of State school superintendent.

In a number of the States strenuous efforts have

been made by those opposed to woman suffrage to have the right to vote upon the question of "license or prohibition" generally extended to woman. No State has as yet extended equal suffrage to women, nor has any woman yet been called upon to fill the higher political and judicial offices of the State or nation. England, accustomed to women occupying the highest office in the kingdom, more easily extends the franchise, subject to a property qualification, to unmarried women and widows.

Professional Rights.—The civil right of choosing one's profession or trade apparently guaranteed to all citizens by the Declaration of Rights, adopted as a constitutional provision in all of the States and in Amendment XIV. of the U. S. Constitution—has not until recently been practically recognized as a right of women in any of the States, and now but partially prevails throughout the United States.

The profession of medicine is open to women in all of the States, and thousands of women in the United States are successfully engaged in this profession. Women are admitted upon equal terms with men into the medical department of many American colleges and universities. There are also numerous medical colleges—chartered and well-endowed—for women exclusively, and medical societies, both State and national, are gradually recognizing their right as medical practitioners to become members thereof, in full fellowship.

All of the States in which the question has been raised have either by direct legislation or by a generic interpretation of the existing law recognized women's right to enter the legal profession—Pennsylvania being one of the first in which application was made, and one of the last to extend this recognition to women. In Pennsylvania a woman attorney-at-law may, as an officer and appointee of the court, serve as master and examiner in equity cases, in which office she is clothed with the power of the court to subpoena witnesses and to administer the oath, but may not be appointed by the governor as a notary public. In Connecticut, Massachusetts, New York, and generally in the Western States woman may act as notary public, United States and State commissioner of deeds, and very generally as administratrix and executrix. The University of Pennsylvania in Philadelphia, Howard University in Washington, Washington University in St. Louis, Columbia Law College of New York, also many other law colleges east and west, afford women equal opportunity with men to become qualified as legal practitioners and confer upon them the degree of Bachelor of Law. Probably not more than one hundred women in the United States are actually engaged in the legal profession.

The government neither recognizes nor denies woman's right to enter the clerical profession. The orthodox religious denominations very generally refuse to ordain her as a minister, but the Society of Friends and the most liberal religious sects give her official recognition. Women occupy high and responsible positions as educators, public and private, authors, editors, artists, and musicians, and in commercial life, and although they may receive the well-earned degree of Doctor of Medicine, Doctor of Dental Surgery, Doctor of Philosophy, Bachelor of Laws, Bachelor of Arts, Bachelor of Music, and Master of Arts—no theological school is yet open to them, and as yet they are ineligible for the degree of Doctor of Divinity.

Neither do the oldest colleges and universities admit women in all departments to a full course of instruction. Harvard, to meet the demand for their higher education, has created a department known as the Harvard Annex, in which they may study and receive a certificate of proficiency. Manual schools of training are now being established in connection with schools for girls, and normal and art schools, also business and commercial colleges very generally afford educational opportunities to women and girls.

Women and girls are generally admitted into all

trades, subject to the laws prohibiting child labor, and are very generally admitted into labor organizations, but are not found at the stock exchange. Female children may be bound out or apprenticed to learn a trade or as domestic servants by their guardians, parents, or if paupers by the town or municipal authorities.

Family Rights.—A girl generally becomes of age at twenty-one; but in some of the States, as in Vermont, she is of age at eighteen, or, as in some parts of the United States, at the time of marriage, provided the marriage takes place before she arrives at the regularly prescribed age of legal majority. She, however, arrives at the age of consent so as to be capable of committing crime at from twelve to sixteen years, and may at this age generally contract a valid marriage—although in many of the States to marry a girl who is a minor without the consent of her parents or guardians is a misdemeanor punishable with fine and imprisonment. In Louisiana marriage is a partnership in which there is community of interests. In all the other States marriage is a civil contract, regulated and controlled by the law of the State in which the parties reside, and may generally be solemnized by a clergyman or by a justice of the peace, or other civil magistrate. In New York, Pennsylvania, and some other States this contract may become completed by any sufficient words or form chosen by the parties in the present tense.

The legal disabilities of married women, arising under the common law legal merger of the wife's individuality in that of her husband, who thereby becomes the head of the house and family, obtains in some of the States so that a married woman may not make a valid contract except as to her own estate. In Ohio, New York, Georgia, Nebraska, and Wyoming, in consequence of this inability to contract, a married woman may not act as an administratrix. These disabilities are gradually being superseded by a general recognition of a reciprocity of duties and a joint tenancy in rights and responsibilities in the married relation, so that in many States married women may make contracts and enforce them by legal action; also are liable on their ante- and post-nuptial contracts.

In the Eastern States a married woman is entitled to respect and honor from her children, but generally is not entitled to their custody nor bound for their maintenance and education, unless she has a separate estate and the father is unable to support them. On becoming a widow the mother is invested with full parental authority, is bound for their support and entitled to their earnings.

In the newer Western States the more liberal law is that the father and mother have equal parental rights, duties, control, and custody of their legitimate children, and in all of the States, in case of a separation of the parents, the custody of their children is determined by the court, having reference only to the welfare of the child and the ability of the parents, which provision may be inserted, in case there is a judicial separation, in the deed of separation.

An unmarried woman has all the rights and duties of parental control of an illegitimate child, and may inherit from and transmit property by the laws of descent through said child. Female heirs in the United States are under no disability as to their intestate succession to real estate, as in England, but their right to administration is in some States postponed in favor of an older male heir.

Marriage may be dissolved by the law of the State in which the parties reside, or by the law of the State in which the husband has his domicile, or in that where the wife has acquired a legitimate residence and citizenship, and is the libellant in the case, for causes specified by the laws of the several States. But very generally desertion, cruel and barbarous treatment, wanton indignities to the person too great to be endured, adultery, imprisonment for three years, and conviction of an ignominious crime are grounds upon which to found a proceeding in divorce, subject to the

rules of practice in the State in which the action is brought. In this proceeding the husband and wife stand upon an equality, the husband being compelled to furnish the wife with counsel fees and alimony during the pendency of the suit if she has not a sufficient separate estate. A woman may not testify to any confidential communications of her husband, nor against her husband, nor the husband against his wife, unless in case of a proceeding in divorce. Neither can a wife be sued by her husband for her tort committed during coverture unless in a proceeding in the nature of a divorce.

Married women may maintain an action of slander against their husbands. They may also maintain an action against their husbands upon an ante-nuptial contract, in which the husband abrogated his marital rights under the statute law in consideration of marriage, such contract being good as between the parties.

Married women may not be arrested or imprisoned for debt in any State, but may be imprisoned for contempt of court. They are generally liable for their torts, and all women, married or single, are liable to the criminal law of the State to the full penalty of the law, even though that be death. Women may maintain an action in damages for breach of promise and for seduction in their own right.

Property Rights.—The laws governing the rights of property of married women form a large part of the laws of the several States in regard to women. There is nothing peculiar in the law governing the property rights of unmarried women and widows, except in those States in which there is a property qualification of suffrage, the rights of unmarried women and widows arising from the ownership of property are not the same as those of men.

Prior to 1848 the common law of England, as to the property rights of married women, prevailed very generally throughout the United States. In the years 1848 and 1850 several of these existing States passed a Married Woman's Property Act, securing to a married woman all legal and equitable estates owned by her at the time of her marriage or acquired by her during coverture by gift, devise, or purchase, other than from or through her husband, for her sole and separate use, to be hers absolutely, and not liable to be taken in execution for her husband's debts.

These acts very generally empowered her to dispose of her separate estate by sale, her husband giving his consent thereto and joining in the deed of conveyance, also by last will and testament (her husband having first given his written consent thereto), subject to the husband's right of curtesy, or otherwise to dispose of it according to the terms of the articles of settlement by which her separate estate was created.

These acts, designed only to protect the separate estate of the wife from execution for the husband's debts, were so construed as to give to the husband, as the natural guardian of the wife, the exclusive right of control and management, also the rents and profits of her separate estate, thus depriving her entirely of the rights of ownership—so "jealous" was the law for the "protection of the rights of the wife." These laws all failed to emancipate her person from the common law control of the husband, so as to recognize her right to her earnings after marriage, or to any interest in their joint earnings other than her dower, which, as at common law, she had in all lands possessed by the husband during coverture. Many of these older States have since so modified their laws as to give to married women absolute power to dispose of their separate estate by will, subject only to the husband's right of statute or common law curtesy, and to secure to a married woman her own earnings, either as a *feme sole* trader, or by petition filed declaring her intention to claim her earnings subsequent to the date of the petition, the effort being to gradually remove the legal disabilities of married women as to property, and to secure to them all the rights of ownership consistent

with the common law idea of marriage. The newer States erected since that period have very generally made more liberal laws, equalizing the property rights of the husband and wife in the separate estate of the other, making a statutory dower and curtesy which shall be equal, or abolishing all dower and curtesy and giving widow and widower equal rights under the intestate laws, both in their separate and joint estates; in short, recognizing the legal individuality of the wife, and giving a community of interests with equal rights of control over the property secured by their joint earnings after marriage.

Some of the States, as Mississippi, Delaware, and Indiana, have also abolished all dower and curtesy, and given instead statutory rights under the intestate laws, while Florida, West Virginia, and Louisiana have created a statutory dower of a life-interest in all of the estates of the husband and in their joint earnings. In general both the husband and wife must join in the deed of conveyance of the joint property, and of the property acquired by either before marriage; but in many of the States the husband may yet mortgage his property and the property secured by their joint earnings, such property standing in his name, without the wife joining in the deed of conveyance. Massachusetts gives all the property to the widow if there are no children, if the property does not exceed in value \$5000. Some other States make the limited value which the childless widow may take \$20,000, the surplus being divided among the relatives of the husband; but if there are no kindred of his living, then the widow may take the entire estate. Pennsylvania gives the widow and widower equal shares in the separate estates of husband and wife; if there are no children, the husband and widower possesses absolutely the joint property secured and acquired by their joint earnings after marriage, unless during the lifetime of the wife she is recognized as a business partner, while the widow, if there are no children, has one-half of the personalty absolutely, and but a life-interest in one-third of the realty, the remaining portion being given to the relatives of the husband; but in case there are no kindred of the husband living, she takes, under the intestate laws, the entire property, as does the widower, without regard to her kindred, if there are no children.

In New Jersey, Maryland, and South Carolina the common law rights of the husband and widower still prevail as to the property acquired after marriage and the separate property of the wife, while the widow takes but the common law portion in the husband's estate.

A very general provision is made for the exemption of certain property from execution for the benefit of the family, ranging from the sum of \$300 to a homestead of 160 acres of land; or if located within a town or city, a homestead of the value of \$5000, which homestead can neither be mortgaged nor sold unless the wife joins in the deed of conveyance and a separate acknowledgment is taken from her. These homestead laws are for the benefit of the wife and children. To understand the laws governing the rights of property of married women accurately it is necessary to become familiar with the statutes of each State, but in general it may be stated that the wife has the absolute control and management of her separate estate, and is entitled to receive therefrom the rents and profits, and appropriate the same to her own use, and may make valid contracts for the benefit of her own separate estate, upon which she may sue and be sued; and while the tendency is uniform and steady throughout the United States to equalize the property rights of married men and women, and while married women may very generally have the rights of ownership over their own separate earnings after marriage secured to them, the husband has generally the superior right of control and ownership of the property acquired by their joint efforts after marriage—a vestige of the common law merger of the legal individuality of the wife in that of

the husband destined soon to be relegated like its other provisions to the past. (See DIVORCE, HUSBAND AND WIFE, INTERNATIONAL LAW, etc.) (C. B. K.)

WOOD, GEORGE B. (1797–1879), physician and medical author, was born in Greenwich, Cumberland co., N. J., March 13, 1797. He began his education in New York but afterwards entered the University of Pennsylvania where he graduated in 1815, and received his degree of M. D. in 1818. In 1820 he delivered a course of lectures on chemistry, and in 1822 was appointed to the chair of chemistry in the Philadelphia College of Pharmacy, and in 1831 to that of materia medica in the same school. In 1835 he was appointed professor of chemistry and pharmacy in the University of Pennsylvania, which position he filled for 15 years, with eminent distinction. In 1850 he was transferred to the chair of the theory and practice of medicine, which he continued to fill till 1860, when he resigned and was appointed *professor emeritus*. Dr. Wood had devoted himself earnestly to the advancement of his students and had promoted the interests and enhanced the reputation of the University of Pennsylvania. He procured at great expense living specimens of exotic plants for exhibition to his students. In 1865 he endowed, in connection with the university, an auxiliary faculty of medicine consisting of five chairs: zoölogy and comparative anatomy, botany, geology and mineralogy, hygiene, medical jurisprudence and toxicology. In 1859 Dr. Wood was elected president of the American Philosophical Society. He died March 30, 1879. Besides preparing a *History of the University of Pennsylvania* (1827), Dr. Wood was author of a number of works which rank high in medical literature. Among these were *Treatise on the Practice of Medicine* (2 vols., 1847), which passed through several editions and was adopted as a text-book by the University of Edinburgh; and *A Treatise on Therapeutics and Pharmacology* (2 vols., 1856). *Pharmacopœia* (1850), prepared with the aid of Dr. Bache, was adopted by the national convention of physicians, and became the basis of the present *United States Pharmacopœia*. His *Dispensatory of the United States* (1st ed., 1833), a work thoroughly exhaustive in its description of many medical agents peculiar to the American practice, has gone through 16 editions, the later editions having been revised by his son, Dr. Horatio C. Wood, and others.

WOOL. See SHEEP.

WOOLSEY, THEODORE DWIGHT, president of Yale College, was born in New York city, Oct. 31, 1801. He graduated at Yale in 1820, studied law and theology at Princeton, and was a tutor at Yale for two years. He then spent three years in Germany, studying Greek at Leipsic, Bonn, and Berlin. On his return in 1831 he was made professor of Greek at Yale College. In 1843 he assisted in founding the *New Englander*, and was one of its editors. In 1846 he was chosen president of Yale College, and held this office for 25 years, during which the institution was enlarged and improved in many ways. Since 1871 he has retired from public duties, but was president of the American Company of revisers of the English New Testament from 1871 to 1881, and has been engaged in a variety of literary work. He edited as college text-books, Euripides' *Alcestis* (1834); Sophocles' *Antigone* (1835) and *Electra* (1837); Æschylus' *Prometheus* (1837) and Plato's *Gorgias* (1843). He also published *Introduction to the Study of International Law* (1860; 5th ed., 1879); *Divorce and Divorce Legislation* (1869; 2d ed., 1882); *Religion of the Present and the Future* (1871); *Political Science* (2 vols., 1877); *Communism and Socialism* (1880). He has also contributed to the leading reviews.

WORM. See EARTH-WORM.

WRIGHT, SILAS (1795–1847), statesman, was born at Amherst, Mass., May 24, 1795; removed in infancy to Addison co., Vt. His father was a farmer in moderate circumstances; his ancestor had been one of the

first settlers of Springfield and Northampton. He graduated at Middlebury College, Vt., 1815, and after admission to the bar in 1819 settled at Canton, St. Lawrence co. Here he became an active member and officer of militia, and rapidly rose to prominence in State affairs, opposing Clinton and espousing the cause of Van Buren. He was sent to the State Senate in 1823, and to Congress in 1827, where he helped to frame the tariff of 1828, which he afterwards considered "a great error." Re-elected 1829 his seat was disputed, and he resigned it to succeed Marcy as comptroller of New York. This post he held four years, and during that time was a member of the Democratic State and national conventions. He was sent to the U. S. Senate 1833 for an unexpired term, and re-elected 1837 and 1843. In this body he won a high reputation and the compliments of Webster. Benton entitled him "the Cato of the Senate." He supported Pres. Jackson's measures, opposed the U. S. Bank, and voted for Clay's compromise bill. He was a delegate to the convention which nominated his friend, Van Buren, and strove to prepare the public mind for the independent treasury plan. The bill, after three failures, was passed July 1, 1840. He favored Van Buren's bankrupt bill, and labored for his re-election in 1840; supported the tariff bill of 1842, and the bank vetoes of Tyler, but opposed the other measures of that President. On the slavery question he occupied a middle ground, favorable neither to the meddling with the institution as it stood nor to the extension of its area; he resisted the extreme proposals of Calhoun, and approved measures looking towards abolition of slavery in the District of Columbia. A speech at Canton, July 4, 1839, promulgated his opinions on this topic. He declined the Chief-Justiceship, offered by Tyler in 1844, and in that year he defeated Fillmore in the contest for the governorship of New York, and resigned his seat in the Senate. This, as the issue proved, was a mistake, for he was better fitted to the national arena than to a smaller one, and to a legislative than to an executive office. Long practice had made him more familiar with measures than with men, a statesman rather than a politician. His term was troubled by the agitations of the Anti-renters and outrages of the "Indians;" these he suppressed with a strong hand, putting down an insurrection in Delaware co., and declining to pardon persons sentenced to terms of imprisonment, though he advised the mitigation of future laws by abolishing distress for rent, and other measures to modify a system which had become oppressive. His party was then divided into "Hunkers" and "Barnburners" (*q. v.*); he would lead neither, but followed a middle course, first opposing revision of the State constitution and then approving the bill for a convention after it had passed. He was renominated and defeated in 1846, and died at Canton, Aug. 27, 1847. In manners he was always a plain countryman, and this failure at home may have gone to his heart. See his *Life* by J. S. Jenkins (1847) and by J. D. Hammond (1848).

WYMAN, JEFFRIES (1814-1874), comparative anatomist, was born in Chelmsford, Mass., Aug. 11, 1814, his father, Dr. Rufus Wyman, being the first physician of the Maclean Insane Asylum, the earliest institution of its kind in New England. Young Wyman was prepared for college at Phillips Academy, Exeter, entered Harvard in 1829 and graduated in 1833. He studied medicine with his father and Dr. Dalton and took the degree of M. D. in 1837. His first appointment after graduation was as demonstrator to Dr. J. C. Warren, professor in Harvard University. Soon afterward he received the appointment of curator of the Lowell Institute, and in 1841 delivered a course of lectures before the Institute. He used the money earned by this for a voyage to Europe and attended the lec-

tures of the most noted anatomists, physiologists, and natural historians in France and England. In 1843 he was appointed professor of anatomy and physiology in Hampden College, Richmond, Va., and in 1847, Hersey professor of anatomy in Harvard; and began the formation of the museum of comparative anatomy with which his name is associated. In its behalf he was wont to make long voyages in America, Europe, and Asia. In 1856 he was made president of the Boston Natural History Society, filling this position till 1870, and in 1857 was chosen president of the American Association for the Advancement of Science. On the foundation of the archaeological museum by Mr. Peabody of London in 1866, he was appointed its curator, an office which, as well as the Hersey professorship, he held till his death. Prof. Wyman was one of the four members in addition to Prof. Agassiz who constituted the faculty of the Museum of Comparative Zoölogy, and entered with unflagging interest into all the large designs of his illustrious colleagues, who regarded him as ranking among the greatest comparative anatomists. A threatened attack of periodical catarrh compelled him in August, 1874, to leave Cambridge for the White Mountains, but before doing so he put both his museums into the most perfect order. On Sept. 4, 1874, he succumbed to a sudden hemorrhage which proved almost immediately fatal, the place of his death being Bethlehem, N. H. Prof. Wyman was the author of numerous scientific papers on anatomical and physiological subjects, the titles of 64 of which appear in the *Catalogue of Scientific Papers*, published by the Royal Society of London.

WYTHE, GEORGE (1726-1806), statesman, jurist, and signer of the Declaration of Independence, was born in Elizabeth City co., Va., of a wealthy family. His education was mostly private, and largely his own work in later years: his youth was spent in reckless dissipation. At thirty he altered his course, was admitted to the bar 1757, and the next year entered the House of Burgesses, where he acquired the greatest consideration and influence. He was one of the earliest and most ardent of patriots, and near the end of 1764 was a member of the committee appointed to draw up a petition to the king and addresses to Parliament. The remonstrance to the Commons on the proposed Stamp Act was written by Wythe, and his colleagues found it much too outspoken for prudence or propriety. As a member of the Continental Congress, 1775-7, he held the same views, and was ripe for independence. With Mason and R. H. Lee he framed the Virginia constitution in 1776; some months later, with Pendleton and his pupil Jefferson, he was set at a revision of the State laws. The next year he was Speaker of the House of Delegates and one of the three judges of Chancery; in this court he disregarded his popularity in maintaining the rights of British creditors. The war, which he so strongly favored, caused the loss of much of his property. He was professor of law at William and Mary College 1779-89. In the Constitutional Convention, and in that of Virginia, which ratified the document, he was active and prominent on the side of union. The court was reorganized in 1786 and he made sole chancellor. He was "singularly able to foresee the latent powers of great men, and help them to great careers." One of the most determined of the Virginia abolitionists, his will freed his slaves and made provision for them. To legal abilities and acquirements of a high order he united a liberal taste for letters, eminent social gifts, and a fondness for instructing and influencing the young. He lived at Richmond from 1789, and there died by poison, June 8, 1806; judicial proceedings failed to bring the supposed murderer to punishment. Jefferson, to whom his library and instruments were bequeathed, said that "no man ever left a character more venerated."

Y.

YALE UNIVERSITY. This famous institution of learning at New Haven, Conn., was named from an early benefactor, Elihu Yale, F.R.S. (1648-1721), born at New Haven, to which his father Thomas had emigrated 1738. The family returned to England 1658, and he never revisited America, but went about 1678 to India, where he acquired wealth, married a native lady, and was governor of Fort St. George, at Madras, 1687-92. Taking home a quantity of Eastern products about 1700, he had them sold at the first auction known in England. He became governor of the East India Company. But his name is preserved by his gifts of books and money, amounting in all to nearly £500, to the nascent school at his birthplace. In 1717 Cotton Mather had advised these donations, and on their account the collegiate house, erected in 1718, received his name, which in the charter of 1745 was extended to the institution. He died in London, July 22, 1721. A college had been in view from the settlement of New Haven in 1638, but Massachusetts urged that Harvard was enough for all New England. The project was revived by a few ministers and on Oct. 9, 1701, a charter was granted for a "collegiate school," and the government vested in a rector and ten fellows, all clerical. Saybrook was chosen as "the most convenient place at present," and Pierson, pastor of Killingworth, put in charge. For six months he taught a solitary student at home; in September, 1702, seven more came, a tutor was chosen, and a commencement held. The transfer to New Haven in 1716 was vehemently opposed, and most of the library lost in the process. For many years the rector was assisted only by two or three tutors; the charter of 1745 changed his title to president. A professor of divinity was added in 1755, and in 1771 one of mathematics, physics, and astronomy, though this chair was not permanently filled till 1794. Before the Revolution occasional grants were made by the legislature; in 1792, the State gave some \$30,000, and added to the Board of Fellows the governor, lieutenant-governor and the six senior assistants in the Council. For the last senators were substituted from 1818, and these by request of the corporation were in 1872 displaced by graduates, one to be chosen annually, to serve six years. These have been the only changes in the government.

The presidents have been Abraham Pierson, 1701-7; Samuel Andrew, *pro tem.*, 1707-19 and 1722-5; Timothy Cutler, 1719-22; Elisha Williams, 1725-39; Thomas Clap, 1739-66; Naphtali Daggett, 1766-77; Ezra Stiles, 1777-95; Timothy Dwight, 1795-1817; Jeremiah Day, 1817-46; Theodore D. Woolsey, 1846-71; Noah Porter, 1871-86; Timothy Dwight (a grandson of his namesake), 1886. The growth of the institution has been chiefly within the present century. Under the vigorous administration of the first Dr. Dwight the faculty was strengthened in 1802 by the acceptance of Benjamin Silliman (for whom see *ENCYCLOPEDIA BRITANNICA*), as professor of chemistry; in 1805 J. L. Kingsley was made professor of Hebrew, Greek, and Latin. A department of medicine was established in 1812, of theology in 1822, of law in 1824. As reorganized in 1871, the college has also departments of philosophy and the arts. The last now includes the academical department or "Yale College," the Sheffield Scientific School, begun 1847 and endowed 1869, the courses for graduates first arranged in 1847, and the School of the Fine Arts, founded in 1864 by A. R. Street.

Degrees were first given in law in 1843, in philosophy in 1852, in theology in 1867. The present number of graduates is about 13,000. There are some 72 professors, 50 or more tutors, instructors, lecturers, etc.; 117 students in divinity, 26 in medicine, 94 in law, 58 in fine arts, 291 in the scientific school, 69 in the graduate courses, and 614 in the college proper, making a net total of 1245. The annual cost of tuition in the college and scientific school is \$150, and in the other departments somewhat less; in that of theology it is free. Beneficiary aid is given to students needing it, and there are sundry fellowships, scholarships and prizes. Changes have recently been made in the direction of greater freedom of study, though to a less extent than at Harvard; in 1885 four-fifths of the work of the seniors, and over half that of the juniors, was made elective. Over ninety elective studies are now open, besides several courses of lectures. The Sheffield Scientific School received in 1863 through the legislature the national appropriation under the law of July, 1862, for agriculture and the mechanic arts, yielding some \$8000 per annum; it gives the degree of Ph.B. and of Civil and Mechanical (or Dynamic) Engineer.

The University buildings occupy a square of some nine acres in the midst of New Haven, adjoining the public green. They are numerous and of various dates; the most recent are the Sloane Memorial laboratory for physics, opened 1884; Lawrence and Dwight halls, 1886; and the Kent chemical laboratory. The handsomest is that of the School of Fine Arts, which cost \$175,000; to this the Trumbull paintings were removed in 1868. The Peabody Museum of National History was erected 1876, at a similar cost, from the proceeds of a gift made in 1866; it has geological, zoological and mineralogical collections, with a curator for each. The observatory was built from a bequest of O. F. Winchester. The University Library contains about 135,000 volumes, the Linonian and Brothers' Library 29,500, and those of various departments bring the sum total up to 188,000. The invested funds amount to \$2,000,000, and the annual income from tuition over \$150,000. *The Annals of Yale* were written to 1766 by President T. Clap, and to 1831 by E. Baldwin. Prof. W. L. Kingsley prepared its *History* (2 vols., 1879), and Prof. Franklin B. Dexter is engaged on a still more elaborate one, of which one volume has appeared. He has also published a neat *Handbook* of the College.

YANCEY, WILLIAM LOWNDES (1814-1863), proslavery politician, was born at Ogeechee Shoals, Ga., Aug. 10, 1814. After admission to the bar and a brief sojourn in South Carolina, he removed to Alabama, 1837, became an editor, was sent to the State Assembly and Senate, and to Congress 1844-7. For the next ten years he was little known to the country at large, but was gathering reputation and influence in what he considered his country. His whole mind and heart were given to the South and to her "peculiar institution," and of that cause he was the most adroit, brilliant and indefatigable champion, though he long labored, conspirator-like, in the dark. General attention was first drawn to him by the unauthorized publication of his so-called "Scarlet Letter," dated June 15, 1858, to James Slaughter; in this he assumed for the South a revolutionary attitude, urged the formation of committees of safety, and organization in the Cotton States to resist Northern aggression. Undaunted by this premature exposure of his plans, he continued his

crusade with almost unexampled energy and activity, laboring with tongue and pen throughout his section to bring Southern sentiment to a point at which continued union with the North would be no longer possible. He wrote, Sept. 4, 1858: "I am a secessionist and not a revolutionist, and would not precipitate, but carefully prepare to meet an inevitable dissolution," which became inevitable largely through his efforts. The biographers of Lincoln call him "the Wendell Phillips of the South, a born agitator, the brain and soul of the proslavery reaction." The course of the National Democratic Convention of 1860 was outlined and almost dictated by him three months before it met; at the Alabama Convention in January, he said: "The States' Rights men should present their demands. If denied, they should secede from the convention, appeal to the whole people of the South, and organize another." In the event of the election of a Republican to the presidency, he provided a plan for State conventions, whereby "the South should seek her independence out of the Union." As he said, so it was done. At the Charleston Convention in April, he was the leading spirit and (to Southern ears) the most welcome and persuasive orator. He showed the Southern members their mistake in admitting theoretical objections to slavery, and assured them that the only logical Democratic position was one of reverence for the institution as essentially good and holy. A majority having accepted Douglas's platform, the Alabama delegate set the example of withdrawal from the Convention, April 30, and were followed by those of the other Cotton States. At the Baltimore Convention in June, Yancey and his co-workers were present, and effected (if they had not done it before) a complete severance of the party, passing to a convention of their own at Richmond. These schemes of disunion had already been explained and denounced in the Senate (May 16) by Douglas, who bore witness to the "ability, courage and sincerity" of Yancey. He was in his element for the last time at the Convention of his State in January, 1861, requiring submissive reverence to the ordinance of secession from the Union, and urging "the penalties of treason" for those who disobeyed it, the members from the Northern counties, not then prepared to go all lengths at once, scoffed at his position, and burned him in effigy. He went abroad in March as a Confederate Commissioner to seek for recognition in Europe, but was unsuccessful; he was an agitator rather than a diplomatist, and could better kindle a fire than support or direct the flame. Returning in February, 1862, he was sent to the Confederate Senate, but died near Montgomery, Ala., July 28, 1863.

YELLOW FEVER. See **FEVER.**

YELLOWSTONE NATIONAL PARK. Of

the many striking examples of natural phenomena in America there are none to surpass those included within the limits of the government reservation known by the above title, which, by Act

of Congress of March 1, 1872, was "dedicated and set apart as a public park or pleasuring ground for the benefit and enjoyment of the people." The marvels of this locality, of which rumors had for some years been afloat, were first made known in 1869 by a party of surveyors who visited the Yellowstone region, and who were followed in 1870 by an expedition under Gen. Washburn, surveyor-general of Wyoming Territory. The report of its wonders excited much interest, and in 1871 a government exploring party under Professor F. V. Hayden visited, explored, and mapped the district, and gave the first detailed report of its striking features of natural scenery and phenomena. Congress at once took measures to preserve it from spoliation or speculative occupation, by setting it aside as a national park for

the permanent use of the people. It was well worthy of this prompt action, for in its special range of phenomena it has no rival upon the earth, and is well worthy the name of "The Northern Wonderland," which Professor Hayden gave it, in distinction from "The Southern Wonderland" of New Zealand.

The Yellowstone Park is situated in the extreme northwestern portion of Wyoming Territory, extending slightly beyond its boundaries into Idaho and Montana, and embraces an oblong tract 55 miles east and west, and 65 miles north and south. Its area is 3575 square miles, the whole of which is at an altitude of more than 6000 feet above sea level. The Yellowstone Lake, which is included within its borders, has an altitude of 7788 feet, while its bordering mountain ranges are from 10,000 to 12,000 feet high, and covered with perpetual snow. This region, while containing varied examples of striking natural scenery, is specially notable for the hot springs and geysers which it possesses in extraordinary abundance, they being without parallel in the world in number and magnificence. These are the final stages of a great volcanic activity which seems to have affected the whole region in recent geological times, and whose temperature conditions still exist at no great distance below the surface. Outside this region, geysers (periodical eruptive springs) are found only in Iceland and New Zealand, the so-called geysers of California being rather fumaroles, or vapor vents. In magnificence of display, however, the great geysers of Iceland are far surpassed by those of the geyser basin of Firehole River, in Yellowstone Park.

The Yellowstone region is, in its geographical features, one of the most interesting of North America. Within its limits or in its vicinity are the sources of several of the great rivers of the continent, which flow from that centre to the east, west, and south.

On the north are the head waters of the Yellowstone; on the west those of the principal forks of the Missouri; on the south and southwest those of the Snake, an affluent of the Columbia, and of the Green, a branch of the Colorado; and on the southeast, those of the Wind River. The Yellowstone, a tributary of the Missouri, is, with the exception of the Colorado, the most remarkable river on the continent. It has its source in Yellowstone Lake, near the southeast corner of the park. This lake, 22 miles long by 10 to 15 wide, is nearly surrounded by snow-clad mountains, its waters are exquisitely clear, its shores rugged but picturesque. The lake is fed by the Upper Yellowstone, after a run of 25 miles from its sources. From its north end flows the main stream of the Yellowstone, with a course of 1300 miles to the Missouri. Near its point of exit from the lake is a belt of hot springs 3 miles long by $\frac{1}{4}$ mile wide, some of them extending into the lake. About 15 miles below the lake the river descends to the lower level in two magnificent cataracts, that known as the Upper Falls being 140 feet in vertical height. About a quarter of a mile below this are the majestic Lower Falls, one of the principal attractions of the park. There the stream falls down a declivity of about 330 feet in height, forming a cataract which far surpasses that of Niagara in beauty, though not its equal in grandeur. Below this the river enters the Grand Cañon, a mighty cleft in the volcanic rocks, 20 miles long, with perpendicular sides from 200 to 500 feet high. There is no scenery of the kind in the world that surpasses this cañon in sublimity, even the Grand Cañon of the Colorado, though exceeding it in dimensions, not surpassing it in grandeur of effect, while its many colored walls give it a magnificence of aspect not to be indicated by any description. Just below the cañon the main stream is joined by Tower Creek, which flows for 10 miles through a

See Vol.
XXIV. p.
730 (p. 734
Am. Rep.).

deep and gloomy cañon known as Devil's Den, in which the basaltic rock is evolved into multitudes of tower-like pinnacles and columns, just above its mouth the creek breaks into a highly picturesque and beautiful fall of 156 feet in vertical height, which constitutes one of the chief attractions of the locality. Below this point the Yellowstone flows through an open country, bounded by lofty hills.

The Yellowstone, though not the region of the great geysers, possesses a remarkable abundance of hot springs, significant of excessive volcanic activity in past times. Some of these are dead, their former existence being indicated by calcareous deposits; others are evidently failing; but many are still in full activity. There is an interesting group of these springs on the east side of Mount Washburn, extending over an area of 10 to 15 square miles. But the most remarkable group, not merely in that locality but in the world, is that of the Mammoth, or the White Mountain Hot Springs, near the northern boundary of the Park. These extend from the margin of Gardiner's River, up the sloping side of White Mountain, to an elevation of nearly 1000 feet above the river level. As springs they are less remarkable at present than some of those in other regions of the Park, but the conditions produced by their former history give them peculiar value. An area of about two square miles is covered by snow-white calcareous deposits, which extend over the entire side of the mountain, and present the appearance of a series of frozen cascades.

The steep mountain sides are ornamented with a succession of semi-circular basins, with margins from a few inches to 6 or 8 feet in height, which are scalloped and adorned with bead-like tracery in every shade of scarlet, green, and yellow, on a white groundwork. The water from the active springs gathers in pools in these basins, and flows over their margins in cascades, gradually losing its heat as it descends the mountain slope. On the summit of the hill is a large spring, whose dimensions are 25 by 40 feet. Its water is perfectly transparent, while the sides and rim of basin are beautifully ornamented with coral-like and other forms of calcareous deposits, of many shades of color. The overflowing water of this basin makes its way down the hill in the cascades described, while the whole scene, with the delicate fretwork of its terraces and its exquisitely soft shades of color, is of a beauty seldom equaled. The branch of the Northern Pacific Railroad which enters the Park from Livingston, ends near this locality at Cinnabar, whence coaches convey tourists six miles further to the Mammoth Hot Springs Hotel, which is the initial point of the usual Park tours.

Another interesting locality on the Yellowstone, about ten miles below the falls, is Sulphur Mountain, which rises on the west side of the river to a height of 150 feet from a nearly level plain. This hill is perforated by numerous fissures and craters, from which sulphurous vapors issue in profusion, while the sides of the fissures are lined with crystals of sulphur, and the ground is hot from internal fires. Near by are some springs of boiling mud. Two miles to the east of this locality is another remarkable group of mud springs, and a few miles above Sulphur Mountain occurs what is known as Mud

Volcano, a crater of boiling mud 25 feet across. The surface of the mud is about 30 feet below the crater level, and is in constant ebullition, while dense clouds of steam rise to a height of several hundred feet. By the occasional explosive outbursts masses of mud are hurled to great distances. There are three large hot springs in the vicinity, one of them a geyser, with a period of activity about every six hours.

The whole region of the Yellowstone Park contains from 5000 to 10,000 hot springs. These are chiefly of two kinds, calcareous and silicated, and deposit lime or silica around their borders, often in elaborate and elegantly ornamented forms, whose colors vary almost as greatly as their shapes. The temperature of the calcareous springs range from 160 to 170 degrees or over, the boiling point of the region being from 198 to 199 degrees. The Gardiner River hot springs are principally calcareous; in other places, as on Firehole River, the springs are silicated.

The most surprising phenomena of the Park, its geysers, are principally found on the stream just named, and near Shoshone Lake, at the head of Lake Fork of the Snake River. Firehole River is a fork of the Madison, which in its turn is a tributary of the Missouri. Within the locality here indicated there are probably 50 geysers which throw columns of water to a height of from 50 to 200 feet, while the vents of all kinds number thousands. On every side is seen evidence of volcanic activity on

Pulpit Terrace.

a stupendous scale in past ages, of which the geysers and hot springs form the slowly subsiding remnant throughout the Park, indeed, the work of ancient lava outflows is visible in broad sheets of basalt, which form mesas or table lands in the valley, while on the hills volcanic breccias are weathered

into varied and fantastic forms. On the Firehole River the geysers compose two large groups, included within an area of about 30 square miles. Here much of the ground is covered with a snowy

Mud Volcano.

deposit from the geyser waters, while the surface of the variously shaped mounds from which the waters spring is in some cases exquisitely ornamented by deposits like "scalloped embroidering set with pearly tubercles." In other cases the deposit of silica assumes the most fantastic forms. Occasionally it is deposited in a gelatinous condition to a depth of 3 or 4 inches, resembling starch paste. Trunks and branches of trees immersed in these waters quickly become covered with a stone-like deposit of silica; or are petrified, in popular language.

Of the two geyser basins on the Firehole, the Lower Basin contains a number of interesting geysers, about half a dozen in all, one of which throws a column of water to the height of 60 feet and another to half this height. Its boiling springs number 693 in all. Between the two basins are the Halfway Springs, the principal one of which is a large cauldron of 250 feet diameter, with walls of about 20 feet high. From it rise constant clouds of steam, while its overflowing waters make their way to the river over a snowy platform of their own deposits. In this locality is the great Excelsior Geyser, whose eruptions are very irregular, but whose great power is attested by the roar which accompanies its outbursts, and the dense volume of steam which it emits.

The Upper or Great Geyser Basin is far more wonderful than the lower in its manifestations of subterranean activity, and as a geyser group has no parallel in the world. It covers an area of about three square miles, extending for several miles along the river, with a width from half a mile to a mile. The river banks here are composed of silicious deposits of the springs, and, in the words of Professor Hayden, are "literally honey-combed with springs, pools and geysers that are constantly gurgling, spitting, steaming, roaring and exploding." Most of the springs and geysers are near the river. The springs are very numerous, there being 414 boiling springs, and many others of lower temperature and tranquil. The average temperature is about 170°. The large geysers number 26 in all. At the head of the valley, near its southern extremity, appears the remarkable geyser, known as Old Faithful, from the frequency and regularity of its discharges. At intervals of about an hour it shoots up a column of water 6 feet in diameter to a height of from 100 to 150 feet, continuing to play for about 6 minutes. When it ceases the water disappears, but an underground hiss of steam indicates the continued activity of the eruptive forces.

On the other side of the river from Old Faithful is the Beehive, so called from the shape of its mound. It throws a column of 2 or 3 feet diameter to a height of from 100 to 220 feet, and continues to play from 5 to 15 minutes. About 200 yards distant is the Giantess, one of the largest of the geysers. This has an oval aperture of 18 by 25 feet, down which one can look for a hundred feet without seeing water, though it can be heard gurgling below. At intervals of about 11 hours, however, the water is hurled upwards in a grand column of 20 feet diameter, to a height of 60 feet, while several smaller jets rising through this carry the discharge occasionally to the extreme height of 250 feet. The eruption continues for about 20 minutes. At a short distance, Sawmill Geyser throws an almost continuous steam to a height of 10 or 15 feet; while near by is Grand Geyser, one of the most powerful, its column of 6 feet diameter at bottom being thrown in a succession of jets to a height of 175 to 200 feet, and continuing for 20 minutes. Its period of eruption is irregular, and is preceded by rumbling noises and shaking of the ground, while the cloud of steam which accompanies the eruption ascends to a height of more than 1000 feet.

Near Grand is a small geyser, known as the Turban, from the peculiar shape of its mound, and beyond this is Giant Geyser, whose water is thrown from a cone 10 feet high and 25 feet diameter at base, diminishing to 8 feet at top. This throws a column of 6 feet diameter, and plays for hours. In 1871 Dr. Hayden found it to play 1 hour and 20 minutes, the water being thrown to a height of 140 feet, but Lieut. Doane, who visited the locality in the preceding year, describes it as playing 3½ hours at times, and throwing its column from 90 to 200 feet. In addition to the geysers described may be named the Castle, which in 1870 threw a column 3 feet in diameter to a height of 140 feet for 3 hours together, and in 1874 played for 40 minutes to a height of 250 feet; the Grotto, throwing its stream from 25 to 60 feet; the Punch Bowl, the Soda, the Pyramid, the Bath, etc., all named from certain peculiarities of form or character, while others worthy of notice are yet unnamed.

Another geyser basin exists at the west end of the western arm of Shoshone Lake, its springs and geysers being said by Prof. Hayden to be not surpassed in beauty and hardly less active than those of Firehole Creek. North of the Firehole geyser basin is the Norris basin, which contains two important geysers, the Monarch and the Hurricane, the latter a recent outburst, and one of the most

vigorous displays of subterranean energy to be seen in the Park. Between this and the Firehole basin is the Gibbon Paint Pot basin, with 500 springs of boiling mud, of every shade of color, and the Gib-

gers within the northern boundary of the Park. Hotels have been built, and several others are to be erected, so that ere long the whole Park promises to be well provided with accommodation for travellers.

Then, too, excursion arrangements are so shaped, that tourists can enjoy the pleasures of the Park in complete safety and at greatly reduced cost. The way to see the wonders of the Park to best advantage, is, at present, by camping out, while all its important localities can be readily visited on horseback. In addition to the marvels of scenery there is excellent hunting and fishing, the Park being full of large and small game, while the rivers and lakes afford excellent sport to the angler. The Act of Congress forming the Park, however, provides that the Secretary of the Interior shall take steps to prevent a wanton destruction of fish and game within its boundaries, and against their capture or destruction for merchandise or profit.

This provision is destined to prove of great advantage in the preservation of the herbivora of the West, the bison, elk, antelope, Rocky Mountain sheep, etc., which have of late years been so recklessly slaughtered, and which are threatened with speedy extinction. It is reported that of those animals a few hundred bison, and several thousand elk, deer, antelopes, and mountain sheep have found a place of refuge within the limits of the Park, and with proper protection, which will no doubt be accorded, there need be no need of these interesting species becoming extinct. Their presence here, if they become

extinct elsewhere, will in the future add another to the many attractive features of the Yellowstone National Park. (C. M.)

YOSEMITE VALLEY. The remarkable and famous mountain cleft or valley known under this title (which is of Indian origin and signifies "large grizzly bear") is situated on the course of the Merced River, in Mariposa County, California, on the western slope of the Sierra Nevada Mountains, and nearly midway between the northern and southern extremities of the State. It is distant 140 miles from San Francisco, in a line nearly due east, but over 220 miles by the usually travelled routes. The valley through which flows the Merced is nearly level, its length being about 6 miles, its width varying from $\frac{1}{2}$ mile to nearly 2 miles, but in that small space is found some of the most magnificent natural scenery in the world. The valley, in fact, is inclosed between lofty granite walls, which rise almost vertically, and are from 3000 to 6000 feet in height; this height being rendered more impressive by the absence of a talus, or sloping heap of debris, at their feet. At several points over these precipitous walls flow streams, which in the season of rains and melting snows form cataracts of unrivalled beauty and magnificence. In the early spring, indeed, to the larger waterfalls are added numerous cascades, as the minor streams and rivulets made by the rains flow over the edge of the mountain walls, and dart downward in lines of glancing light to the valley below. At this season the combined effects of cascades and cataracts give an indescribable beauty and grandeur to the scene. The nearly vertical walls of the valley and their great height, both absolutely and as compared with the width of the space between them, with the added charms of the waterfalls, form features of unusual attractiveness, to which may be added the fact that during the proper season the valley is one vast flower bed, the ground being carpeted thickly with plants of great variety, which bear flowers of every hue and of great brilliancy of color, while the air is filled with their fragrance. Trees also in great variety adorn the val-

"Old Faithful" Geyser.

bon Cañon and Falls, the latter a beautiful cascade of 160 feet height.

The curiosities here named are by no means all the marvels of the Park; there are hot springs

Crater of Giant Geyser.

falls, and other attractions in several other localities, and there is scarcely a portion of the Park without its objects of interest. It is doubtful if there is any locality on the face of the globe that contains so much of the attractive and wonderful, while it is said to surpass in the number of its hot springs and geysers all the remainder of the earth.

The Park was formerly difficult of access, but the railroad extension of recent years has overcome this difficulty, there being a Yellowstone Park branch of the Northern Pacific Railroad which lands passen-

ley level, some of them of centuries' growth and great loftiness, though they are dwarfed by the towering cliffs against which they measure their height. To these varied elements of beauty must be added the stream which wanders down the centre of the valley. It is of mountain origin and icy cold, while its water is so clear that every detail of its bottom can be seen, the mountain trout which haunt its depths being revealed in all their graceful charms to the eye of the eager angler.

The Yosemite was discovered in the spring of 1851 by a party of soldiers in pursuit of a band of predatory Indians, who made this valley their stronghold, considering it inaccessible to the whites. The report of its great beauty quickly brought tourists thither, and has spread until the Yosemite Valley has become one of the places of pilgrimage of the sightseers of the world. In 1864 Congress took measures to preserve this remarkable locality from the greed of speculation by setting it aside as a permanent national park. The Yosemite Valley and the Mariposa grove of big trees were granted to California on the express conditions that they should be kept "for public use, resort, and recreation," and "be inalienable for all time." They were placed under the care of guardians appointed by the government, the guardian of the Yosemite residing in the valley during the season in which it is accessible to visitors, and having under his direction a small army of guides, drivers, care-takers, and others who make up the resident population. In addition to the residence of the guardian, the valley contains three well-kept hotels, a post-office, a small chapel, in which religious services are held, and various minor buildings, such as stables, guides' cottages, etc., these being all so situated as to detract in no sense from the attractions of the natural scenery.

In passing up the valley from its outlet the first grand feature that meets the eye is the huge and lofty cliff known as "El Capitan." This is not so high by several thousand feet as some of the others, yet rises so vertically from base to summit, and stands out so prominently from the general line of the mountain wall as to make it the most striking feature of the valley, and the chief of its lofty cliffs. "El Capitan" is 3300 feet high, its sides are bare and smooth, and, in the words of Prof. J. D. Whitney, "it is doubtful if anywhere in the world there is presented so squarely cut, so lofty, and so imposing a face of rock."

As if to soften the grandeur of this great cliff, on the opposite side of the valley there descends in indescribable charm one of the most beautiful of its many cascades, the celebrated Bridal Veil Fall. In this fall the stream leaps from the brow of a cliff 900 feet high, and comes down in a broad sheet of tremendous white spray, which is converted into mist by the depth of the descent. As it is swayed by the wind in ever changing yet ever pleasing outlines, the title given it seems most appropriate to its fleecy beauty. Opposite this fall, down a deep recess of rock near the lower corner of El Capitan, the Virgin's Tears Fall flows over the cliff and descends 1000 feet, in a beautiful cascade, which, however, is only visible during the early spring, the stream completely disappearing during the dry season. In fact a visit in the season of rains and of melting snows is necessary to see any of the falls in their perfection, the largest of them losing much of its beauty in the period of drought.

A short distance above the Bridal Veil Fall appears Cathedral Rock, a nearly vertical cliff, 2660 feet high; and just beyond it tower The Spires, two graceful columns of granite which are in part isolated from the valley walls, and rise above the edge of the cliff like the towers of a Gothic cathedral. From one point of view they appear of equal height and

symmetrical form, and add much to the charm of this portion of the valley. Further up, and on the opposite side, rises a triple group known as the Three Brothers, or, as named by the Indians, the Pompompasus or Leaping Frog Rocks. They seem, indeed, from below, like three huge frogs sitting with their heads all turned in the same direction. The highest of them is 3830 feet in altitude, and affords from its summit a superb view of the valley and its surroundings. Nearly opposite these projects a cliff which terminates with a slender obelisk of granite. The total height is 3043 feet, and its resemblance to a gigantic watch tower has gained it the name of Sentinel Rock.

Directly opposite Sentinel Rock appears what is justly regarded as the most wonderful feature of the valley scenery, the grand and lofty Yosemite Falls, which descends in all 2660 feet in two cataracts and a series of cascades. The first of these is a sheer fall of 1500 feet. Then the stream descends 626 feet in a series of cascades, and makes a final plunge of 400 feet to the bottom, seeming to shake the earth as it strikes the ground, while its roar can be heard far away. The stream is about 25 feet in width at the crest, while the total depth of the descent is more than a half mile. No other cataract in the world can compare with this in height and romantic beauty, the celebrated Stubbach of Switzerland being greatly its inferior both in height and volume. It is seen at its best from May to July. In August and September both this and the Bridal Veil Fall shrink almost to nothing from decrease in volume of their feeding streams. East of the fall is a cliff 3030 feet high whose summit is easily reached by a trail up Indian Cañon and affords a magnificent view of the whole region.

At a short distance above the Yosemite Falls an affluent flows into the Merced, making its way to the level below, not by a cataract but down a deep gorge known as Teneya Cañon. At this point are some of the most remarkable cliff effects of the whole valley. From the northern wall rises a lofty columnar mass known as Washington Column, immediately to the left of which is a series of immense arches in the rock strata named The Royal Arches. Above these towers the symmetrical North Dome to the height of 3568 feet. Opposite to this, on the other side of Teneya Cañon, rises the loftiest and most imposing of all the cliffs of the valley, the vast granite crest known as the Half Dome, which ascends to a height of 4737 feet. This mighty cliff, nearly a mile in vertical height, was long considered inaccessible, but in 1879 improvements were made by which tourists can now reach its summit, though not without a long and weary climb. Between these domes lies in the bed of the cañon the exquisite little Mirror Lake, formed by an expansion of Teneya Fork, while beautifully reflect in its sparklingly clear surface the surrounding cliff and the overhanging mass further up the cañon called Mount Watkins.

The main valley ends about two miles above Yosemite Falls. Here it branches into two cañons, one traversed by the main stream of the Merced, the other, or South Fork Cañon, traversed by a stream of minor size, yet which, at some distance up the rough and difficult cliff, descends in a fine fall estimated at 600 feet in height, which has received the soft sounding name of Illilouet Fall. Down the main cañon flows the Merced River, its waters making their way from the upper level in two grand cataracts and a series of rapids and cascades which are among the most attractive features of the valley scenery. The first fall reached in ascending the cañon has been named Vernal Fall. Here the whole stream, of perhaps 100 feet in width and of considerable depth, plunges vertically downward about 400 feet in a cataract of great grandeur.

A steep path, whose difficult portions have been made easy of ascent by a stairway, lead to the summit of this ledge, from which a fine view down the cañon can be had. For a mile beyond this point the river flows in a series of cascades and rapids of striking character, the water rushing with a force approaching that of the rapids at Niagara, while on the north side of the cañon appears a huge isolated, and nearly perpendicular mass, known as the Cap of Liberty, 2000 feet high, and little inferior to the Half Dome in grandeur. Beyond this is seen the second fall of the Merced, Nevada Fall, which in height, volume, and impressive character of the surrounding scenery, ranks with the grandest waterfalls of the world. The height is about 600 feet, but the descent is not quite vertical, there being a rocky ledge near the summit which throws a part of the water aside with a peculiar twist which gives the fall a character of its own and adds greatly to its scenic effect.

Such are the principal features of this remarkable valley, which, taken as a whole, with its great variety and profusion of grand and beautiful scenery, is matchless among the valleys of the world. In the vicinity of the Yosemite are waterfalls which elsewhere would be considered as marvels of scenery, but which are left unnoticed by travellers in consequence of the much greater attractiveness of those of the valley. The cañon of the Tuolumne River, parallel with and a few miles north of the Merced, is full of attractive scenery, the stream descending 4650 feet in a flow of 22 miles, and presenting at short intervals cascades of great beauty and variety. At its mouth the gorge opens into a valley resembling the Yosemite in its general features, yet inferior to it in grandeur, and lost sight of in the superior charm of its neighboring rival.

Of the several localities from which a general view of the valley may be had, three deserve special mention. One of these, well named Inspiration Point, is situated at the entrance of the valley. Here the Merced flows through a deep and narrow gorge, and entrance can be effected only by a climb over the lofty cliffs at one side or other of the river. In this climb the tourist suddenly finds himself on Inspiration Point, and the whole valley laid out before him in one grand bird's-eye view, in which its looming cliffs and gleaming falls are all visible up to the point where the Merced flows out from its cañon to the broad level of the valley. The first view but adds zest to the delight with which the marvels revealed are afterwards to be seen near at hand. Up the valley nearly opposite the mouth of Tenaya Cañon is another outlook, known as Moran's Point, being the point of view from which the artist, Thomas Moran, sketched his celebrated picture of the Yosemite Valley. This point of view is 2000 feet high, and brings under the eye most of the scenic effects of the valley. A yet more embracing view can be had from Glacier Point, just east of Moran's Point, and about 3000 feet high. From this height the tourist can look over the obstructions to view at lower altitudes, and take in almost the entire valley at a glance.

As to the formative agencies of this noble production of nature scientists somewhat disagree, though the balance of evidence seems in favor of the active agency of glaciers in scooping out the valley. Abundant traces of glacial action can yet be seen, some of the cliff sides being polished to a slippery smoothness by the action of the ice. Earthquakes also seem to have had their share in the work, and huge fragments of rock now lie on the valley level, which have evidently been torn from the summits of the cliffs above. Probably still other agencies were at work, for nature seldom performs such mighty labors with a single tool. The whole surrounding scenery is full of evidence of titanic forces, and from the

summit level above the valley the Sierras present a magnificent panorama of mountain and valley scenery, unsurpassed even in Switzerland. (C. M.)

YOUMANS, EDWARD LIVINGSTON, editor of scientific publications, was born of poor parents, June 3, 1821, in Albany co., N. Y. Assisting his father in the work of the farm, the want of means, and also an affection of the eyes, that adhered to him throughout life, prevented him from entering college. Later he studied medicine, and devoted himself to popularizing the sciences, in which he discovered a remarkable aptitude, both as a lecturer and as a compiler. He avoided technicalities, and his style was distinguished by a clearness of phrase and elegance of diction little known till then in the scientific domain. It was doubtless owing to the reputation he had acquired, in these respects, as well as to his powers of broad, though strictly scientific generalization, that he was named, though himself a non-collegian, for the presidency of Antioch College, which he declined. However, he accepted there, in 1866, the chair of chemistry, as non-resident professor, and delivered a course of lectures. In 1856 the writings of Herbert Spencer attracted his attention, and thereupon a correspondence ensued which led to a life-long friendship, which brought about the publication of Spencer's *works* in America. In 1872 Prof. Youmans induced Messrs. Appleton & Co., of New York, to start the *Popular Scientific Monthly*, which, under his editorship, attained deservedly high position among the scientific periodicals of the world. He also planned the "International Scientific Series," comprising works by the ablest European and American authorities, and went to Europe to perfect the scheme by which the simultaneous publication in London, Paris, New York, Leipsic, Milan, and St. Petersburg was inaugurated. Besides his contributions to the two works, *Correlation and Conservation of Forces* (1864) and the *Culture demanded by Modern Life* (1867), Youmans prepared the "Class-book of Chemistry" (1851), the "Hand-book of Household Science" (1857), and other manuals. In his editorial labors he was constantly and ably assisted by his sister, Miss Elizabeth L. Youmans. He died at New York, Jan. 18, 1887. (J. W. W.)

YOUNG, CHARLES AUGUSTUS, astronomer, was born at Hanover, N. H., Dec. 15, 1834. He graduated at head of his class at Dartmouth College, in 1853, then taught classics at Phillips Academy, Andover, Mass., until 1856, when he accepted chair of mathematics, natural philosophy, and astronomy in Western Reserve College, at Hudson, Ohio. He was called thence in 1865 to Dartmouth College to assume the same chair, in which he had been preceded by his father and grandfather. In 1877 he removed to Princeton College, N. J., to take the chair of astronomy. He was entrusted with an expedition to Denver, Col., to observe the eclipse of the sun on July 29, 1878. As member of the observing party at Burlington, Iowa, of another eclipse, Aug. 7, 1869, he discovered the green line of the corona spectrum, and identified it with line 1,474 of the solar spectrum. As member of the Coast Survey observing party, on Dec. 22, 1870, at Jerez, Spain, he discovered what is called the "reversing layer" of solar atmosphere, giving a bright-line spectrum correlative to the ordinary dark-line spectrum of sunlight. As member of the Coast Survey party at Sherman, Wyoming Territory (summit of the Pacific Railroad), he made solar spectroscopic observations. In 1874 he was assistant astronomer in Prof. Watson's party to Peking, to observe the transit of Venus. He devised a form of automatic spectroscopic; established what is known as Doppler's principle applied to light experimentally, and measured the sun's rotation by the displacement of the lines in the spectrum. Prof. Young is a member of the National Academy of

Science, and other prominent learned societies. He holds high rank as a writer of scientific papers. He has lectured in various cities, and by his treatise *The Sun* (International Science Series) (1881), he has popularized the topics of solar physics and spectroscopy. His latest publication is a *Manual of Astronomy* (1888). (J. W. W.)

YOUNG, EDWARD, statistician, was born Dec. 11, 1814, at Falmouth, Nova Scotia. After receiving academic education, and spending some years in Windsor, N. Y., in mercantile affairs, he emigrated in 1835 to Indiana, where he engaged in business. In 1840 he returned to his native province, married and settled in Halifax, N. Y., where besides his commercial pursuits he edited the *Oliver Branch*, a pioneer temperance publication. After sustaining losses in shipping, he removed in 1849 to Boston, and, in 1851, to Philadelphia where in partnership with E. T. Freedley, he published books and a weekly newspaper devoted to American industries. Their most important publication was *A History of American Manufactures from 1608 to 1866* (3 vols.), edited by Dr. J. L. Bishop, his wife's brother. A statistical work compiled by Mr. Young having attracted attention he was offered and accepted a place in the U. S. treasury department, removing to Washington in 1861. Here, as chief of division, he superintended the compilation of the statistics of industry and prepared for publication a voluminous report on the *Manufactures of the United States*, the precursor of all such reports. In 1865 he accepted a place on the revenue commission tendered by its chairman, Hon. D. A. Wells, but soon resigned. On Mr. Wells' recommendation Congress authorized the establishment of a bureau of statistics, and when this was organized in 1866 Mr. Young was made its chief clerk. After a few months, he was promoted to be chief of the bureau, which under his management became the peer of the older similar institutions in Europe. In addition to the official reports, Mr. Young published a *Special Report on Immigration* (1871), which was translated into German, French, and Swedish, and circulated by tens of thousands throughout Europe, the result being a great annual increase in the influx of immigrants. In the same year he published a *Special Report on the Customs—Tariff Legislation of the United States*. For these two works the Columbian University conferred on him the degree of Ph.D. His most important work is *Labor in Europe and America* (1875), which gives the results of personal investigation of the condition of the working classes. Dr. Young withdrew from the bureau of statistics in 1878, and lent his services for a few months to the Canadian government in the construction of tariff-tables, etc. He has since been U. S. Consul at Windsor. (J. H.)

YOUNG, ROBERT (1822-1888), author of the *Analytical Concordance*, was born at Edinburgh, Scotland, Sept. 10, 1822. He became a printer, then a bookseller, editor and publisher of many works in Hebrew and other Oriental languages. In 1856 he went to India to superintend the Mission press at Surat. After his return in 1861, he conducted for some years a missionary institute, and in 1867 visited the United States. He was still diligent in labors connected with the Bible, its original languages, and its interpretation. In his well-known *Analytical Concordance* he gives 311,000 references, and furnishes various means of comparing the English text of any passage with the original. He afterwards prepared *Contributions to a New Revision; Concordance to 8000 changes of the Revised New Testament; Dictionary and Concordance of Bible Words and Synonyms; Twofold Concordance to the New Testament*, and other helps to the study of the Scriptures, besides an excellent translation of the New Testament. He died Oct. 14, 1888.

YOUNG MEN'S CHRISTIAN ASSOCIATION.

Within the past half century organizations of men have been formed under this name for the purpose of carrying on evangelical work in addition to that commonly performed by the system of Protestant churches. In 1845 the first Association of this kind was formed in London, and in 1851 the first one in America was organized in Boston. The second Association was formed in Montreal; the third in Buffalo; and the fourth in New York city. The general American Association, in its early days, met in annual conference; but latterly has convened once in two years. It was at the instance of the American Association that the first International Conference was held in Paris in 1855. At that conference the "Evangelical Test" was adopted, which limits the active membership to members of Evangelical churches. Every association admits others as associate members, but they are not allowed to vote upon amendments to the constitution, or to hold offices.

The latest reports (1888) of the condition of the organization show that there were 3804 associations in the world at the time when the tabular statements were prepared, of which 1240 were in the United States and Canada. Great Britain has 624, Germany 673, and the rest of Europe 1171. The remaining associations are scattered through Asia, Australasia, South Africa, South America, Mexico, and other countries. The island of Ceylon has 15. Full statistics of membership, property owned, and like details are available only in regard to the American associations, but the strength of the Y. M. C. A. in the world may be inferred from the fact that in 1888 the American associations, one-third of the total number, have 175,811 members, showing an increase of about 29,000 or 13 per cent. in one year. These American associations have real estate to the value of \$6,708,230, showing an increase of about \$1,100,000, or nearly 20 per cent. in a year. The total value of the property owned is put at \$7,261,658, and there are pledges for building funds to the amount of \$1,325,000. In 1887 about \$1,200,000 was spent to carry on the associations in the United States and British America, or \$200,000 more than in 1886. The buildings erected for the several associations in the cities of New York, Philadelphia, Boston, Buffalo, Cleveland, and Albany are of a most beautiful and substantial character.

Briefly stated, the work accomplished by the associations may be given as follows:—1. They have founded such historic union prayer meetings as those in Fulton Street, New York, from 1856 to the present time, and in Jayne's Hall, Philadelphia, from 1857 to 1868. 2. They have acted the part of Howard societies in seasons of devastating epidemics. 3. During the civil war they organized and supported the U. S. Christian Commission, which followed the armies with beneficent ministrations to the bodily and spiritual wants of the soldiers. (See CHRISTIAN COMMISSION.) 4. The American associations originated and secured stringent legislation in the United States for the suppression of obscene literature, and began the vigorous efforts still continued for the thorough enforcement of this legislation. 5. They have stimulated a taste for the best reading by carefully selected libraries. 6. They have encouraged the most instructive class of lectures. 7. They have been foremost in evangelistic services in their home fields and throughout entire states and provinces. 8. In times of sudden calamity to any community by fire, storm or flood, they are ever ready as almoners of the benevolent to distribute wisely their contributions in aid of sufferers, and in scores of cities and towns during the trying season of the year they secure and discriminatingly use funds for the

relief of the deserving destitute poor of the community.

In reviewing the work of the American associations since the close of the civil war, the following points seem worthy of special notice: 1. The American associations have sought to give rightful prominence to specific work for the improvement of young men. 2. They have maintained their organizations for the purpose of associating Christian young men in this work for their fellows. 3. They have insisted that this improvement is to be sought primarily by the conversion of the soul and the consecration of the life to the love and service of Jesus Christ. 4. They have united Christians of the various churches in this work and in other work that can best be performed by united effort. 5. In summer they hold hundreds of open-air services every week. 6. In thinly settled districts they have united the active members of various churches in holding meetings in homes and school-houses. 7. They carry the gospel among the 800,000 railroad employes of the country. 8. They organize the young men in colleges for Christian work. 9. They co-operate with German-speaking Christian young men for the salvation of their fellows. 10. They bring together into Christian sympathy and companionship the young men of Canada and the United States, the young men of the North and the South, so promoting peace upon earth, good will to men. 11. This broad, deep work they accomplish by insisting that Christian laymen are called of God to give time and effort as well as money to active service in winning souls and leading them to Christ. 12. While these associations are each individually active in carrying on this varied and useful work, they also meet yearly in international, state and provincial conventions, and by means of deliberative action and efficient committees promote the common cause.

The several states have passed laws incorporating nearly all of these associations within their borders. A state executive committee of the Young Men's Christian associations of the State of New York was incorporated in 1886. The same state, in 1883, passed a law incorporating the International Committee of Young Men's Christian Associations. This committee is to be composed of not less than 27 members, one-third of whom are to be elected at each of the international conventions.

As a consequence of the great and good work accomplished by the Young Men's Christian Association, Women's Christian Associations have also been organized to carry on a similar work among females.

(F. G. M.)

YUCCA, a peculiar genus of the family of *Liliaceae*, which is a native of North America, from New Jersey and Iowa to Yucatan, and is most abundant between 25° and 35° N. lat. There are about a dozen well characterized species and many varieties, the stems of the more northerly species being under-

ground, and sending up a tuft of bayonet or dagger-shaped leaves; while the more southerly have an aerial stem, palm-like in some species, the trunk, which reaches 10 to 20 feet in height, being crowned with a dense tuft of leaves. The yucca is known by various common names, as bear-grass, Adam's needle, and Spanish bayonet. *Y. filamentosa*, to which the first two of these names are given, is found in sandy soil from Florida to Virginia and westward. The trunk rises to a foot or less above the ground, and is crowned with the lance-shaped, unarm'd, coriaceous leaves, which bear delicate filaments on the margins. It is from these threads and the sharp-pointed leaves that the name Adam's needle is derived. *Y. angustifolia*, which is abundant between the Mississippi and the Rocky Mountains, is known as the soap plant, the root stocks of this as of other species being full of mucilaginous and saponaceous material, which, under the name of amole, is used as a substitute for soap in many Mexican houses, and also by the negroes of the South. Its leaves are from 1 to 3 feet long, and very stiff and pointed.

Two other United States species, *Y. aloifolia*, the Spanish bayonet, and *Y. gloriosa*, occur from North Carolina southward. The latter gets its title from its magnificent inflorescence. The flowers of the yucca are borne on a flower stem, which rises from the centre of the leaves, and bears a large panicle of snowy white, lily-like blossoms, which are attractive at all hours, but particularly so in the evening, when the flowers are fully expanded. The fruit of the yucca is dry in some species, fleshy in others, and in the latter cases is edible and savory. It is eaten by the negroes of the coast regions of South Carolina and Georgia under the name of banana, which it somewhat resembles. The fruit of *Y. baccata*, a species of Arizona and the neighboring States, is largely eaten in the fresh state by whites and Indians, and is cured by the Indians for winter use. The roots of some species abound in farina, and are used by the Indians as food. Another species is *Y. recurvifolia*, of the sea-coast of Georgia, whose white flowers are occasionally tinged with green and purple.

Several species of yucca are planted for ornament in landscape gardening, while all the plants of the genus have an important economical use, as they yield a fibre of great strength and value. Sisal hemp comes from a member of this genus, and from the leaves of every species may be obtained a long staple. *Y. gloriosa* furnishes a fibre of extreme durability, which is used for cordage, rope, and packing cloth. *Y. filamentosa* also yields a strong fibre, from which ropes have been made of unsurpassed strength. As these plants grow spontaneously on light sandy soils, often of the poorest character, from Virginia to Florida, and are very hardy, they may become of considerable economic value as fibre-yielding plants.

ZECHARIAH. See **PROPHETS.**

ZEISBERGER, DAVID (1721-1808), missionary to the American Indians, was born April 11, 1821, at Zauchenthal, Moravia, and educated at Herrnhut. In 1738 he followed his parents, who were descended from the Bohemian Brethren, to Georgia and two years later removed with them to Pennsylvania, and had a share in founding Bethlehem and Nazareth. In 1743 he narrowly escaped being sent back to Germany with Zinzendorf. In 1745 he began to preach and labor among the Delawares at Shamokin, and soon transferred his efforts to the Iroquois

at Onandaga, N. Y. For 63 years he lived in the woods, devoted to his pious calling, in which he displayed zeal and fortitude not surpassed by any of the Canadian Jesuits, taking long journeys on foot and by canoe, indifferent to hardships and perils. At first he met a good degree of apparent success; the Six Nations adopted him (as did afterwards the Monseys), made him a sachem, and entrusted him with their records. The commotions of those times sadly disturbed and interrupted his peaceful work, and between contending parties or armies, he was exposed to troubles and suspicions, as in the French

war. He settled with his converts at Wyalusing, on the Susquehanna, after the conspiracy of Pontiac, and in 1767 started a mission on the Alleghany. In 1772 he founded Schoenbrunn on the Tuscarawas, in Ohio. After nine years of increasing prosperity and influence, his loyal service to the American government, in preventing the Delawares from taking the field against it, was punished by the British authorities at Detroit, who instigated the Wyandots to destroy his settlements, and had Zeisberger and his assistants tried as spies. What was left of his work was ruined in 1782 by the massacre at Gnadenhutten, in which ninety-six Christian Indians, peacefully returning to their fields, fell at the hands of settlers. Zeisberger, with such of his converts as remained faithful, sought refuge in Michigan, then at New Salem, Ohio, and in 1791 at Fairfield, in Canada. In 1798 they were allowed to repossess their old lands in the Tuscarawas valley. Here, at Goshen, he spent his last years among a few forlorn and drunken Indians, to whom he preached industry and sobriety in vain. He died Nov. 19, 1808, leaving the memory of a devoted if defeated life, and some valuable contributions to philological lore. His *Delaware Spelling-book* (1776; and again 1806 and 1816), *Hymn-book* (1805; reprinted 1847), *Sermons to Children* (1813) and *Harmony of the Gospels* (1821), are all in the Delaware tongue. His *German and Onondaga Lexicon* (7 vols. 4to.), two *Onondaga Grammars*, a *Delaware Grammar and Dictionary*, and some vocabularies, are preserved in MS. in Philadelphia, or at Cambridge, Mass. His *Life and Times* was written by E. De Schweinitz (1870; 2d ed. 1886); his *Diary*, translated by E. F. Bliss, was published in 2 vols. 1885, by the Ohio Historical and Philosophical Society.

ZEPHANIAH. See **PROPHETS**.

ZOECKLER, OTTO, German theologian, was born at Grünberg, Hesse, May 27, 1833. He was educated at Giessen, Erlangen, and Berlin Universities,

graduating in 1856. He began to teach at Giessen, and in 1863 was made professor extraordinary. In 1866 he became ordinary professor at Greifswald, and in the next year began to edit the *Allgemeine literarische Anzeiger* which he conducted for seven years. In 1882 he was made editor of the *Evangelische Kirchenzeitung*. Among his works are *Theologia Naturalis* (1860); *Kritische Geschichte der Askese* (1863); *Hieronymus* (1864); *Die Urgeschichte der Erde und des Menschen* (1868); *Das Kreuz Christi* (1875); *Geschichte der Beziehungen zwischen Theologie und Naturwissenschaft* (2 vols. 1877-79); *Die Lehre vom Urstand des Menschen* (1879); *Gottes Zeugen im Reich der Natur* (2 vols. 1881); *Hand-buch der theologischen Wissenschaften* (3 vols. 1833-84), in which he was assisted by others.

ZUNZ, LEOPOLD (1794-1886), Jewish author, was born at Detmold, Lippe, Germany, Aug. 16, 1794. He was a teacher for some years before he went to Berlin to study philology. There he became preacher to the Jewish congregation in 1820, editor of a newspaper in 1824, and principal of a Jewish school in 1825. In 1835 he was called to Prague as a preacher, but in 1839 returned to Berlin to take charge of a normal school. In 1845 he was appointed member of a government commission to devise measures for the educational improvement of the Jews in Prussia. In 1850 he resigned his position in the normal school, and was afterwards chiefly engaged in literary labor. His researches shed much light on Hebrew literature. He died at Berlin March 17, 1886. As early as 1818 he had published *Etwas über die rabbinische Literatur*, but his chief works were *Die gottesdienstlichen Vorträge der Juden* (1832); *Die synagogale Poesie des Mittelalters* (1855); *Die Ritus des synagogalen Gottesdienstes geschichtlich entwickelt* (1859); and *Litteraturgeschichte der synagogalen Poesie* (1865). His collected works appeared in three volumes (1875-76). He was also engaged with other Jewish scholars on a German translation of the Bible.
